Name	The name for the certificate collection. This name appears at the top of the page in the Keyfactor Command Management Portal for this collection and can be configured to appear on the Management Portal menu under Certificate Collections. It will also appear in other places within the Management Portal where you can reference certificate collections (e.g. expiration alerts and certain reports). Because it can appear on the menu and in selection dropdowns, the name should be fairly short.
Description	The description for the collection. This description appears at the top of the page in the Management Portal for this collection and can be more detailed than the collection name.
Automated	An internally used Keyfactor Command field.
Content	A string containing the search criteria for the collection.
DuplicationField	An integer that sets the type of de-duplication (a.k.a. "ignore renewed certificate results by") to apply to the collection when using the collection in areas of Keyfactor Command that apply de-duplication (e.g. expiration alerts). For more information, see Saving Search Criteria as a Collection on page 38 in the *Keyfactor Command Reference Guide*. Possible values are: **Value** / **Description** 0 / None 1 / Common Name 2 / Distinguished Name 3 / Principal Name
ShowOnDashboard	A Boolean that sets whether the results from this collection are included on the Management Portal dashboard *Certificate Counts by Collection* graph (*true*) or not (*false*).
Favorite	A Boolean that sets whether the collection appears on the Navigator—on the *Certificates* top-level menu dropdown—(*true*) or not (*false*).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon () at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.8.3 GET Certificate Collections

The GET /CertificateCollections method is used to return a list of all certificate collections. This method returns HTTP 200 OK on a success with details about each defined certificate collection. This method allows URL parameters to specify paging and the level of information detail.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: Certificates: *Read*

Permissions for certificates can be set at either the global or certificate collection level. See Certificate Permissions on page 588 in the *Keyfactor Command Reference Guide* for more information about global vs collection permissions.

Table 240: GET Certificate Collections Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Certificate Search Page on page 31. The query fields supported for this endpoint are: • *Name* • *Query*
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *Name*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 241: GET CertificateCollections Response Data

Name	Description
ID	The Keyfactor Command reference ID for the certificate collection. The ID is automatically assigned by Keyfactor Command.
Name	The name for the certificate collection. This name appears at the top of the page in the Keyfactor Command Management Portal for this collection and can be configured to appear on the Management Portal menu under Certificate Collections. It will also appear in other places within the Management Portal where you can reference certificate collections (e.g. expiration alerts and certain reports). Because it can appear on the menu and in selection dropdowns, the name should be fairly short.
Description	The description for the collection. This description appears at the top of the page in the Management Portal for this collection and can be more detailed than the collection name.
Automated	An internally used Keyfactor Command field.
Content	A string containing the search criteria for the collection.
DuplicationField	An integer that sets the type of de-duplication (a.k.a. "ignore renewed certificate results by") to apply to the collection when using the collection in areas of Keyfactor Command that apply de-duplication (e.g. expiration alerts). For more information, see Saving Search Criteria as a Collection on page 38 in the *Keyfactor Command Reference Guide*. Possible values are:
ShowOnDashboard	A Boolean that sets whether the results from this collection are included on the Management Portal dashboard *Certificate Counts by Collection* graph (*true*) or not (*false*).
Favorite	A Boolean that sets whether the collection appears on the Navigator—on the *Certificates* top-level menu dropdown—(*true*) or not (*false*).

Value	Description
0	None
1	Common Name
2	Distinguished Name
3	Principal Name

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon () at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.8.4 POST Certificate Collections

The POST /CertificateCollections method is used to create a new saved collection of certificates or update an existing collection. This method returns HTTP 200 OK on a success with details about the certificate collection.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
Certificates: *Read*
Certificate Collections: *Modify*

Permissions for certificates can be set at either the global or certificate collection level. See Certificate Permissions on page 588 in the *Keyfactor Command Reference Guide* for more information about global vs collection permissions.

Table 242: POST Certificate Collections Input Parameters

Name	In	Description
Name	Body	**Required**. The name for the certificate collection. This name appears at the top of the page in the Keyfactor Command Management Portal for this collection and can be configured to appear on the Management Portal menu under Certificate Collections. It will also appear in other places within the Management Portal where you can reference certificate collections (e.g. expiration alerts and certain reports). Because it can appear on the menu and in selection dropdowns, the name should be fairly short.
Description	Body	**Required**. The description for the collection. This description appears at the top of the page in the Management Portal for this collection and can be more detailed than the collection name. See also *CopyFromId*.
Query	Body	**Required**. A string containing the search criteria for the collection. For example: `"Query": "(IssuedDate -ge \"%TODAY-7%\" AND TemplateShortName -ne NULL) OR (IssuedDate -ge \"%TODAY-7%\" AND IssuerDN -contains \"keyexample\")"` See Certificate Search Page on page 31in the *Keyfactor Command Reference Guide* for querying guidelines. See also *CopyFromId*.
DuplicationField	Body	An integer that sets the type of de-duplication (a.k.a. "ignore renewed certificate results by") to apply to the collection when using the collection in areas of Keyfactor Command that apply de-duplication (e.g. expiration alerts). For more information, see Saving Search Criteria as a Collection on page 38 in the *Keyfactor Command Reference Guide*. The default is 0. Possible values are: **Value** / **Description** 0 / None 1 / Common Name 2 / Distinguished Name 3 / Principal Name
ShowOnDashboard	Body	A Boolean that sets whether the results from this collection are included on the Management Portal dashboard *Certificate Counts by Collection* graph (*true*) or not (*false*). The default is *false*.
Favorite	Body	A Boolean that sets whether the collection appears on the Navigator—on the *Certificates* top-level menu dropdown—(*true*) or not (*false*). The default is *false*.

Name	In	Description
CopyFromId	Body	An integer identifying an existing certificate collection from which to copy the query string. Use the *GET /CertificateCollections* method (see GET Certificate Collections on page 1079) to locate the ID of the collection whose query you wish to copy. When you use this parameter, the permissions, query and description of the existing collection are copied to the new collection. Providing the *Query* or *Description* parameter in the request overrides the copied value and replaces it with the value provided in the request if the requesting user has global *Read* permissions for certificates. If the requesting user is granted *Read* permissions to the collection via collection-level security rather than global security, the *Query* the user provides will be appended to the existing query rather than overwriting it. See the below example.  **Example:** Gina wants to create a new collection using the *CopyFromId* option. She first uses GET /CertificateCollections/{id} to list the collection she plans to copy from and sees the following results: `{ "Id": 10, "Name": "Keyexample Collection", "Description": "Certificates in the Keyexample Domain", "Automated": false, "Content": "CN -contains \"keyexample.com\"", "DuplicationField": 2, "ShowOnDashboard": false, "Favorite": true }` Gina wants her new certificate collection to retain the same collection-level permissions as the *Keyexample Collection*. However, she wants the collection to report on a different domain name. The *Keyexample Collection* is configured to grant collection-level permissions of *Read*, *Edit Metadata*, and *Download with Private Key* to the *Power Users* role. At the Key Example company, users with the Power Users role do not have global certificate *Read* permissions because all certificate permissions are granted using certificate collection permissions. Only full Keyfactor Command administrators have global certificate *Read* permissions. Users with the Power Users role have *Modify* permissions for certificate collections to allow them to create new collections. This level of permissions is significant for what Gina wants to do. Gina holds the Power Users role and is not a full administrator. Gina uses POST /CertificateCollections/Copy (or POST /CertificateCollections—the behavior and output would be the same) to

Name	In	Description

		create a new certificate collection using the *CopyFromId* option with the following command:
		
		`{`
		`"CopyFromId": 10,`
		`"Name": "Keyother Collection",`
		`"Description": "Certificates in the Keyother Domain",`
		`"Query": "CN -contains \"keyother.com\"",`
		`"DuplicationField": 2,`
		`"ShowOnDashboard": false,`
		`"Favorite": true`
		`}`
		
		In the response, Gina sees the following:
		
		`{`
		`"Id": 15,`
		`"Name": "Keyother Collection",`
		`"Description": "Certificates in the Keyother Domain",`
		`"Automated": false,`
		`"Content": "(CN -contains \"keyexample.com\") AND (CN -contains \"keyother.com\")",`
		`"Query": "(CN -contains \"keyexample.com\") AND (CN -contains \"keyother.com\")",`
		`"DuplicationField": 2,`
		`"ShowOnDashboard": false,`
		`"Favorite": true`
		`}`
		
		Notice that Gina has not achieved her desired goal. The new collection contains a query for both the keyexample.com domain and the keyother.com domain. Gina's new query was appended to the existing query rather than overwriting the existing query. This happened because Gina does not have global *Read* permissions for certificates and is done to prevent a user from increasing the scope of certificates they can view.
		
		Gina asks Martha, who is a full Keyfactor Command administrator and has the global *Read* permissions for certificates, to copy the collection for her. Martha first deletes the first Keyother Collection that Gina created and then runs the same command that Gina ran to create a new collection.
		
		In the response, Martha sees the following:
		
		`{`
		`"Id": 16,`

Name	In	Description

		
		`"Name": "Keyother Collection",`
		`"Description": "Certificates in the Keyother Domain",`
		`"Automated": false,`
		`"Content": "(CN -contains \"keyother.com\")",`
		`"Query": "(CN -contains \"keyother.com\")",`
		`"DuplicationField": 2,`
		`"ShowOnDashboard": false,`
		`"Favorite": true`
		`}`
		
		Notice that when Martha runs the command, Gina's goal is achieved.

Table 243: POST Certificate Collections Response Data

Name	Description
ID	The Keyfactor Command reference ID for the certificate collection. The ID is automatically assigned by Keyfactor Command.
Name	The name for the certificate collection. This name appears at the top of the page in the Keyfactor Command Management Portal for this collection and can be configured to appear on the Management Portal menu under Certificate Collections. It will also appear in other places within the Management Portal where you can reference certificate collections (e.g. expiration alerts and certain reports). Because it can appear on the menu and in selection dropdowns, the name should be fairly short.
Description	The description for the collection. This description appears at the top of the page in the Management Portal for this collection and can be more detailed than the collection name.
Content	A string containing the search criteria for the collection. This field contains the same value as *Query* and is retained for backwards compatibility.
Query	A string containing the search criteria for the collection.
DuplicationField	An integer that sets the type of de-duplication (a.k.a. "ignore renewed certificate results by") to apply to the collection when using the collection in areas of Keyfactor Command that apply de-duplication (e.g. expiration alerts). For more information, see Saving Search Criteria as a Collection on page 38 in the *Keyfactor Command Reference Guide*. Possible values are:
ShowOnDashboard	A Boolean that sets whether the results from this collection are included on the Management Portal dashboard *Certificate Counts by Collection* graph (*true*) or not (*false*).
Favorite	A Boolean that sets whether the collection appears on the Navigator—on the *Certificates* top-level menu dropdown—(*true*) or not (*false*).

Value	Description
0	None
1	Common Name
2	Distinguished Name
3	Principal Name

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.8.5 PUT Certificate Collections

The PUT /CertificateCollections method is used to update an existing saved collection of certificates. This method returns HTTP 200 OK on a success with details about the certificate collection.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
Certificates: *Read*
Certificate Collections: *Modify*

Permissions for certificates can be set at either the global or certificate collection level. See Certificate Permissions on page 588 in the *Keyfactor Command Reference Guide* for more information about global vs collection permissions.

Table 244: PUT CertificateCollections Input Parameters

Name	In	Description
ID	Body	**Required**. The Keyfactor Command reference ID for the certificate collection. The ID is automatically assigned by Keyfactor Command. Use the *GET /CertificateCollections* method (see GET Certificate Collections on page 1079) to locate the ID of the collection you wish to update.
Name	Body	**Required**. The name for the certificate collection. This name appears at the top of the page in the Keyfactor Command Management Portal for this collection and can be configured to appear on the Management Portal menu under Certificate Collections. It will also appear in other places within the Management Portal where you can reference certificate collections (e.g. expiration alerts and certain reports). Because it can appear on the menu and in selection dropdowns, the name should be fairly short.
Description	Body	**Required**. The description for the collection. This description appears at the top of the page in the Management Portal for this collection and can be more detailed than the collection name.
Query	Body	**Required**. A string containing the search criteria for the collection. For example: `"Query": "(IssuedDate -ge \"%TODAY-7%\" AND TemplateShortName -ne NULL) OR (IssuedDate -ge \"%TODAY-7%\" AND IssuerDN -contains \"keyexample\")"` See Certificate Search Page on page 31in the *Keyfactor Command Reference Guide* for querying guidelines.
DuplicationField	Body	An integer that sets the type of de-duplication (a.k.a. "ignore renewed certificate results by") to apply to the collection when using the collection in areas of Keyfactor Command that apply de-duplication (e.g. expiration alerts). For more information, see Saving Search Criteria as a Collection on page 38 in the *Keyfactor Command Reference Guide*. The default is 0. Possible values are: **Value** / **Description** 0 / None 1 / Common Name 2 / Distinguished Name 3 / Principal Name
ShowOnDashboard	Body	A Boolean that sets whether the results from this collection are included on the Management Portal dashboard *Certificate Counts by Collection* graph (*true*) or not (*false*). The default is *false*.

Name	In	Description
Favorite	Body	A Boolean that sets whether the collection appears on the Navigator—on the *Certificates* top-level menu dropdown—(*true*) or not (*false*). The default is *false*.

Table 245: PUT CertificateCollections Response Data

Name	Description
ID	The Keyfactor Command reference ID for the certificate collection. The ID is automatically assigned by Keyfactor Command.
Name	The name for the certificate collection. This name appears at the top of the page in the Keyfactor Command Management Portal for this collection and can be configured to appear on the Management Portal menu under Certificate Collections. It will also appear in other places within the Management Portal where you can reference certificate collections (e.g. expiration alerts and certain reports). Because it can appear on the menu and in selection dropdowns, the name should be fairly short.
Description	The description for the collection. This description appears at the top of the page in the Management Portal for this collection and can be more detailed than the collection name.
Content	A string containing the search criteria for the collection. This field contains the same value as *Query* and is retained for backwards compatibility.
Query	A string containing the search criteria for the collection.
DuplicationField	An integer that sets the type of de-duplication (a.k.a. "ignore renewed certificate results by") to apply to the collection when using the collection in areas of Keyfactor Command that apply de-duplication (e.g. expiration alerts). For more information, see Saving Search Criteria as a Collection on page 38 in the *Keyfactor Command Reference Guide*. Possible values are: **Value** / **Description** 0 / None 1 / Common Name 2 / Distinguished Name 3 / Principal Name
ShowOnDashboard	A Boolean that sets whether the results from this collection are included on the Management Portal dashboard *Certificate Counts by Collection* graph (*true*) or not (*false*).
Favorite	A Boolean that sets whether the collection appears on the Navigator—on the *Certificates* top-level menu dropdown—(*true*) or not (*false*).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.8.6 POST Certificate Collections Copy

The POST /CertificateCollections/Copy method is used to copy an existing saved collection of certificates in order to create a new collection. The permissions, query and description of the existing collection are copied to the new collection. Providing the *Query* or *Description* parameter in the request overrides the copied value and replaces it with the value provided in the request. This method returns HTTP 200 OK on a success with details about the new certificate collection.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
Certificates: *Read*
Certificate Collections: *Modify*

Permissions for certificates can be set at either the global or certificate collection level. See Certificate Permissions on page 588 in the *Keyfactor Command Reference Guide* for more information about global vs collection permissions.

Table 246: POST Certificate Collections Copy Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>Name</td><td>Body</td><td>Required. The name for the certificate collection. This name appears at the top of the page in the Keyfactor Command Management Portal for this collection and can be configured to appear on the Management Portal menu under Certificate Collections. It will also appear in other places within the Management Portal where you can reference certificate collections (e.g. expiration alerts and certain reports). Because it can appear on the menu and in selection dropdowns, the name should be fairly short.</td></tr>
<tr><td>Description</td><td>Body</td><td>Required. The description for the collection. This description appears at the top of the page in the Management Portal for this collection and can be more detailed than the collection name.
See also CopyFromId.</td></tr>
<tr><td>Query</td><td>Body</td><td>Required. A string containing the search criteria for the collection.
For example:
<pre>"Query": "(IssuedDate -ge \"%TODAY-7%\" AND TemplateShortName -ne NULL) OR (IssuedDate -ge \"%TODAY-7%\" AND IssuerDN -contains \"keyexample\")"</pre>See Certificate Search Page on page 31in the Keyfactor Command Reference Guide for querying guidelines.
See also CopyFromId.</td></tr>
<tr><td>DuplicationField</td><td>Body</td><td>An integer that sets the type of de-duplication (a.k.a. "ignore renewed certificate results by") to apply to the collection when using the collection in areas of Keyfactor Command that apply de-duplication (e.g. expiration alerts). For more information, see Saving Search Criteria as a Collection on page 38 in the Keyfactor Command Reference Guide. The default is 0. Possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>0</td><td>None</td></tr>
<tr><td>1</td><td>Common Name</td></tr>
<tr><td>2</td><td>Distinguished Name</td></tr>
<tr><td>3</td><td>Principal Name</td></tr>
</table></td></tr>
<tr><td>ShowOnDashboard</td><td>Body</td><td>A Boolean that sets whether the results from this collection are included on the Management Portal dashboard Certificate Counts by Collection graph (true) or not (false). The default is false.</td></tr>
<tr><td>Favorite</td><td>Body</td><td>A Boolean that sets whether the collection appears on the Navigator—on the Certificates top-level menu dropdown—(true) or not (false). The default is false.</td></tr>
</table>

Name	In	Description
CopyFromId	Body	An integer identifying an existing certificate collection from which to copy the query string. Use the *GET /CertificateCollections* method (see GET Certificate Collections on page 1079) to locate the ID of the collection whose query you wish to copy. When you use this parameter, the permissions, query and description of the existing collection are copied to the new collection. Providing the *Query* or *Description* parameter in the request overrides the copied value and replaces it with the value provided in the request if the requesting user has global *Read* permissions for certificates. If the requesting user is granted *Read* permissions to the collection via collection-level security rather than global security, the *Query* the user provides will be appended to the existing query rather than overwriting it. See the below example.  **Example:** Gina wants to create a new collection using the *CopyFromId* option. She first uses GET /CertificateCollections/{id} to list the collection she plans to copy from and sees the following results: `{ "Id": 10, "Name": "Keyexample Collection", "Description": "Certificates in the Keyexample Domain", "Automated": false, "Content": "CN -contains \"keyexample.com\"", "DuplicationField": 2, "ShowOnDashboard": false, "Favorite": true }` Gina wants her new certificate collection to retain the same collection-level permissions as the *Keyexample Collection*. However, she wants the collection to report on a different domain name. The *Keyexample Collection* is configured to grant collection-level permissions of *Read*, *Edit Metadata*, and *Download with Private Key* to the *Power Users* role. At the Key Example company, users with the Power Users role do not have global certificate *Read* permissions because all certificate permissions are granted using certificate collection permissions. Only full Keyfactor Command administrators have global certificate *Read* permissions. Users with the Power Users role have *Modify* permissions for certificate collections to allow them to create new collections. This level of permissions is significant for what Gina wants to do. Gina holds the Power Users role and is not a full administrator. Gina uses POST /CertificateCollections/Copy (or POST /CertificateCollections—the behavior and output would be the same) to

Name	In	Description

		create a new certificate collection using the *CopyFromId* option with the following command:
		
		`{`
		`"CopyFromId": 10,`
		`"Name": "Keyother Collection",`
		`"Description": "Certificates in the Keyother Domain",`
		`"Query": "CN -contains \"keyother.com\"",`
		`"DuplicationField": 2,`
		`"ShowOnDashboard": false,`
		`"Favorite": true`
		`}`
		
		In the response, Gina sees the following:
		
		`{`
		`"Id": 15,`
		`"Name": "Keyother Collection",`
		`"Description": "Certificates in the Keyother Domain",`
		`"Automated": false,`
		`"Content": "(CN -contains \"keyexample.com\") AND (CN -contains \"keyother.com\")",`
		`"Query": "(CN -contains \"keyexample.com\") AND (CN -contains \"keyother.com\")",`
		`"DuplicationField": 2,`
		`"ShowOnDashboard": false,`
		`"Favorite": true`
		`}`
		
		Notice that Gina has not achieved her desired goal. The new collection contains a query for both the keyexample.com domain and the keyother.com domain. Gina's new query was appended to the existing query rather than overwriting the existing query. This happened because Gina does not have global *Read* permissions for certificates and is done to prevent a user from increasing the scope of certificates they can view.
		
		Gina asks Martha, who is a full Keyfactor Command administrator and has the global *Read* permissions for certificates, to copy the collection for her. Martha first deletes the first Keyother Collection that Gina created and then runs the same command that Gina ran to create a new collection.
		
		In the response, Martha sees the following:
		
		`{`
		`"Id": 16,`

Name	In	Description

		
		`"Name": "Keyother Collection",`
		`"Description": "Certificates in the Keyother Domain",`
		`"Automated": false,`
		`"Content": "(CN -contains \"keyother.com\")",`
		`"Query": "(CN -contains \"keyother.com\")",`
		`"DuplicationField": 2,`
		`"ShowOnDashboard": false,`
		`"Favorite": true`
		`}`
		
		Notice that when Martha runs the command, Gina's goal is achieved.

Table 247: POST Certificate Collections Copy Response Data

Name	Description
ID	The Keyfactor Command reference ID for the certificate collection. The ID is automatically assigned by Keyfactor Command.
Name	The name for the certificate collection. This name appears at the top of the page in the Keyfactor Command Management Portal for this collection and can be configured to appear on the Management Portal menu under Certificate Collections. It will also appear in other places within the Management Portal where you can reference certificate collections (e.g. expiration alerts and certain reports). Because it can appear on the menu and in selection dropdowns, the name should be fairly short.
Description	The description for the collection. This description appears at the top of the page in the Management Portal for this collection and can be more detailed than the collection name.
Content	A string containing the search criteria for the collection. This field contains the same value as *Query* and is retained for backwards compatibility.
Query	A string containing the search criteria for the collection.
DuplicationField	An integer that sets the type of de-duplication (a.k.a. "ignore renewed certificate results by") to apply to the collection when using the collection in areas of Keyfactor Command that apply de-duplication (e.g. expiration alerts). For more information, see Saving Search Criteria as a Collection on page 38 in the *Keyfactor Command Reference Guide*. Possible values are:
ShowOnDashboard	A Boolean that sets whether the results from this collection are included on the Management Portal dashboard *Certificate Counts by Collection* graph (*true*) or not (*false*).
Favorite	A Boolean that sets whether the collection appears on the Navigator—on the *Certificates* top-level menu dropdown—(*true*) or not (*false*).

Value	Description
0	None
1	Common Name
2	Distinguished Name
3	Principal Name

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.8.7 POST Certificate Collections ID Permissions

The POST /CertificateCollections/{id}/Permissions method is used to set permissions on a certificate collection. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: Security Settings: *Modify*

Warning: When using this method to update an existing certificate collection, all existing RoleId and Permission information must be submitted along with any updates. Any existing permissions that are not included with their full existing data (RoleId and Permission mappings) on an update using this method will be removed from the permissions for the certificate collection. There is not presently a GET method to retrieve the current state of the permissions for certificate collections.

Note: This method has been deprecated and will be removed from the Keyfactor API in release 11. It has been replaced by the endpoint: PUT /Security/Roles/{id}/Permissions/Collection.

Table 248: POST CertificateCollections {id} Permissions Input Parameters

Name	In	Description
id	Path	**Required**. An integer indicating the ID of the certificate collection to update. Use the *GET /CertificateCollections* method (see GET Certificate Collections on page 1079) to retrieve a list of all the certificate collections to determine the certificate collection ID.
RoleId	Body	An integer identifying the Keyfactor Command security role that you wish to grant collection security permissions to. Use the *GET /Security/Roles* method (see GET Security Roles on page 1630) to retrieve a list of your defined security roles to determine the security role ID to use.
Permissions	Body	An array of the collection permissions that can be granted to the role. Possible values are: • Read • EditMetadata • Recover • Revoke • Delete For example: `"Permissions": [ "Read", "Recover", "Revoke" ]` Permissions for certificates can be set at either the global or certificate collection level. See Certificate Permissions on page 588 in the *Keyfactor Command Reference Guide* for more information about global vs collection permissions.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.9 Certificate Stores

The CertificateStores component of the Keyfactor API (formerly known as the JKS API) provides a set of methods to support management of certificate locations.

Through different remote Keyfactor orchestrators, Keyfactor Command can inventory, install, and remove certificates for each of the store types. For certain store types, additional actions are supported as well. The CertificateStores component provides a way to programmatically schedule jobs for these stores. For more information about certificate stores and their support within Keyfactor Command, see the *Keyfactor Command Reference Guide* and *Keyfactor Command Orchestrator Installation and Configuration Guide*, or contact your Keyfactor

representative. The set of methods in this API component that can be used to manage certificate stores and their scheduled jobs is listed in Table 249: Certificate Stores Endpoints.

Table 249: Certificate Stores Endpoints

Endpoint	Method	Description	
/	DELETE	Deletes multiple certificate stores specified in the request body.	DELETE Certificate Stores on the next page
/	GET	Returns all certificate stores with paging and option to specify detail level.	GET Certificate Stores on page 1100
/	POST	Creates a new certificate store if valid parameters are supplied.	POST Certificate Stores on page 1108
/	PUT	Updates an existing certificate store.	PUT Certificate Stores on page 1128
/{id}	DELETE	Deletes a certificate store by its GUID.	DELETE Certificate Stores ID on page 1148
/{id}	GET	Returns certificate store details for the specified certificate store.	GET Certificate Stores ID on page 1148
/{id}/Inventory	GET	Returns certificate inventory for the specified certificate store.	GET Certificate Stores ID Inventory on page 1161
/Server (*deprecated)	GET	Returns a list of certificate store servers.	GET Certificate Stores Server on page 1163
/Server (*deprecated)	POST	Creates a new certificate store server.	POST Certificate Stores Server on page 1165
/Server (*deprecated)	PUT	Updates an existing certificate store server.	PUT Certificate Stores Server on page 1170
/Password	PUT	Updates the password for a certificate store.	PUT Certificate Stores Password on page 1174
/DiscoveryJob	PUT	Creates a job to find certificate stores.	PUT Certificate Stores Discovery Job on page 1177
/AssignContainer	PUT	Assigns a certificate store to a container.	PUT Certificate Stores Assign Container on page 1182
/Approve	POST	Approves an array of pending certificate	POST Certificate Stores

Endpoint	Method	Description	
		stores.	Approve on page 1190
/Schedule	POST	Creates an inventory schedule for a certificate store.	POST Certificate Stores Schedule on page 1198
/Reenrollment	POST	Schedules a reenrollment of a certificate into a certificate store.	POST Certificate Stores Reenrollment on page 1201
/Certificates/Add	POST	Configures a management job to add a certificate to one or more stores with the provided schedule.	POST Certificate Stores Certificates Add on page 1204
/Certificates/Remove	POST	Configures a management job to remove a certificate from one or more stores with the provided schedule.	POST Certificate Stores Certificates Remove on page 1209

3.2.9.1 DELETE Certificate Stores

The DELETE /CertificateStores method is used to delete multiple certificate stores in one request. The certificate store GUIDs should be supplied in the request body as a JSON array of strings. This endpoint returns 204 with no content upon success. GUIDs of any certificate stores that could not be deleted are returned in the response body. Delete operations will continue until the entire array of GUIDs has been processed.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: CertificateStoreManagement: *Modify*

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Table 250: DELETE Certificate Stores Input Parameters

Name	In	Description
IDs	Body	**Required**. An array of strings indicating Keyfactor Command certificate store GUIDs for certificate stores that should be deleted in the form: `[52fe526d-9914-4239-b74b-b47d0607cf7c,8ec160d9-3242-4eb4-956b-a7651af6c542]` Use the *GET /CertificateStores* method (see GET Certificate Stores on the next page) to retrieve a list of all the certificate stores to determine the certificate store GUIDs.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.9.2 GET Certificate Stores

The GET /CertificateStores method is used to return a list of all certificate stores defined in Keyfactor Command. The results include both approved certificates stores and certificates stores found on discovery but not yet approved. This method allows URL parameters to specify paging and the level of information detail. This method returns HTTP 200 OK on a success with details about the certificate store(s).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateStoreManagement: *Read*

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Table 251: GET Certificate Stores Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Using the Certificate Store Search Feature on page 360. The query fields supported for this endpoint are: • *AddSupported* (True, False) • *AgentAvailable* (True, False) • *AgentId* • *Approved* (True, False) • *Category* (0-Javakeystore,2-PEMFile, 3-F5SSLProfiles,4-IISRoots, 5-NetScaler, 6-IISPersonal, 7-F5WebServer, 8-IISRevoked, 9-F5WebServerREST, 10-F5SSLProfilesREST, 11-F5CABundlesREST, 100-AmazonWebServices, 101-FileTransferProtocol) • *CertificateId* • *ClientMachine* • *Container* (ContainerName) • *ContainerId* • *HasInventoryScheduled* (True, False) • *PrivateKeyAllowed* (0-Forbidden, 1-Optional, 2-Required) • *RemoveSupported* (True, False) • *StorePath* **Tip:** Use the following query to limit the results to only active certificate stores and not include discovery results: `approved -eq true`
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *ClientMachine*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 252: GET Certificate Stores Response Data

Name	Description
Id	A string indicating the GUID of the certificate store within Keyfactor Command. This ID is automatically set by Keyfactor Command.
ContainerId	An integer indicating the ID of the certificate store's associated certificate store container, if applicable (see GET Certificate Store Containers on page 1212).
ClientMachine	The string value of the client machine. The value for this will vary depending on the certificate store type. For example, for a Java keystore or an F5 device, it is the hostname of the machine on which the store is located, but for an Amazon Web Services store, it is the FQDN of the Keyfactor Command Windows Orchestrator. See Adding or Modifying a Certificate Store on page 363 in the *Keyfactor Command Reference Guide* for more information.
Storepath	A string indicating the path to the certificate store on the target. The format for this path will vary depending on the certificate store type. For example, for a Java keystore, this will be a file path (e.g. /opt/myapp/store.jks), but for an F5 device, this will be a partition name on the device (e.g. Common). See Adding or Modifying a Certificate Store on page 363 in the *Keyfactor Command Reference Guide* for more information. The maximum number of characters supported in this field is 722.
CertStoreInventoryJobId	A string indicating the GUID that identifies the inventory job for the certificate store in the Keyfactor Command database. This will be null if an inventory schedule is not set for the certificate store.
CertStoreType	An integer indicating the ID of the certificate store type, as defined in Keyfactor Command, for this certificate store. (0-Javakeystore,2-PEMFile, 3-F5SSLProfiles,4-IISRoots, 5-NetScaler, 6-IISPersonal, 7-F5WebServer, 8-IISRevoked, 9-F5WebServerREST, 10-F5SSLProfilesREST, 11-F5CABundlesREST, 100-AmazonWebServices, 101-FileTransferProtocol)
Approved	A Boolean that indicates whether a certificate store is approved (true) or not (false). If a certificate store is approved, it can be used and updated. A certificate store that has been discovered using the discover feature but not yet marked as approved will be false here.
CreateIfMissing	A Boolean that indicates whether a new certificate store should be created with the information provided (true) or not (false). This option is only valid for Java keystores and any custom certificate store types you have defined to support this functionality.
Properties	Some types of certificate stores have additional properties that are stored in this parameter. The data is stored in a series of, typically, key value pairs that define the property name and value (see GET Certificate Store Types on page 1242 for more information). As of Keyfactor Command v10, this parameter is used to store certificate store server usernames, server passwords, and the UseSSL flag. Built-in certificate stores that typically require configuration of certificate store server parameters include NetScaler and F5 stores. The legacy methods for managing certificate store server credentials have been deprecated but are retained for backwards compatiblity. For more information, see POST Certificate Stores Server

Name	Description

	on page 1165.
	When reading this field, the values are returned as simple key value pairs, with the values being individual values. When writing, the values are specified as objects, though they are typically single values.
	For example, on a GET request for a *PEM* store configured with a separate private key, the contents of this field might be:
	`"{ \"privateKeyPath\":\"/opt/app/mystore.key\", \"separatePrivateKey\":\"true\" }"`
	However, the syntax used when updating the properties sets the value as a key value pair using *value* as the key. For example, on a POST or PUT request for a *PEM* store configured with a separate private key, the contents of this field might be:
	`"{ \"privateKeyPath\":{\"value\":\"/opt/app/mystore.key\"}, \"separatePrivateKey\":{\"value\":\"true\"} }"`
	An example server properties parameter POST for an FTP or NetScaler store would contain:
	`"{ \"ServerUsername\":{\"value\":{\"SecretValue\":\"User_Name\"}}, \"ServerPassword\":{\"value\":{\"SecretValue\":\"Password\"}}, \"ServerUseSsl\":{\"value\":\"true\"} }"`
	An example server properties parameter POST for an FTP or NetScaler store with the username and password stored as PAM secrets would contain (where the Provider value—1 in this example—is the Id value from GET PAM Providers on page 1455):
	`"{ \"ServerUsername\":{\"value\":{\"Provider\":\"1\",\"Parameters\": {\"SecretId\":\"User_Name\"}}}, \"ServerPassword\":{\"value\":{\"Provider\":\"1\",\"Parameters\": {\"SecretId\":\"Password\"}}}, \"ServerUseSsl\":{\"value\":\"true\"} }"`
	Note: There are three standard properties that are used for any built-in certificate store types that require server credentials (e.g. F5):

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>

ServerUsername
ServerPassword
ServerUseSsl

These replace the separate certificate store server records that existed in previous versions of Keyfactor Command. For legacy support, if credentials are not provided through store properties during creation or editing of a certificate store, Keyfactor Command will attempt to find a certificate store server record and copy the credentials from it into the store properties for future use.

Tip: Built-in stores that make use of this field include:

AWS stores use this field to store secured versions of the access key and secret.
F5 REST stores (all types) use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl) and primary node information (PrimaryNode, PrimaryNodeCheckRetryWaitSecs, PrimaryNodeCheckRetryMax) and F5 version (F5Version).
F5 SOAP stores (all types) use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl).
FTP stores use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl).
IIS stores (all types) use this field to store the UseSSL flag and the port for SMB communications.
Java keystores use this field to store type (ProviderType).
NetScaler stores use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl).
PEM stores use this field to store the path to the private key file, if defined, and the Boolean value indicating whether a separate private key path is defined.

</td></tr>
<tr><td>AgentId</td><td>A string indicating the Keyfactor Command GUID of the orchestrator for this store.</td></tr>
<tr><td>AgentAssigned</td><td>A Boolean that indicates whether there is an orchestrator assigned to this certificate store (true) or not (false).</td></tr>
<tr><td>ContainerName</td><td>A string indicating the name of the certificate store's associated container, if applicable.</td></tr>
<tr><td>InventorySchedule</td><td>The inventory schedule for this certificate store. The following schedule types are supported:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Immediate</td><td>A Boolean that indicates a job scheduled to run immediately (true) or not (false).

  Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as null.</td></tr>
<tr><td>Interval</td><td>A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Minutes</td><td>An integer indicating the number of minutes between each interval.</td></tr>
</table>

For example, every hour:

<pre>"Interval": {
   "Minutes": 60
}</pre></td></tr>
<tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>

For example, daily at 11:30 pm:

<pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre></td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>ExactlyOnce</td><td>A dictionary that indicates a job scheduled to run at the time specified with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, exactly once at 11:45 am:
<pre>"ExactlyOnce": {
   "Time": "2022-02-27T11:45:00Z"
}</pre>
Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as ExactlyOnce.</td></tr>
</table>
Note: Although the Swagger Example Value may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint.
</td></tr>
<tr><td>ReenrollmentStatus</td><td>An array that indicates whether the certificate store can use the re-enrollment function with accompanying data about the re-enrollment job. The following reenrollment fields are supported:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Data</td><td>A Boolean that indicates whether the certificate store can use the re-enrollment function (true) or not (false).</td></tr>
<tr><td>AgentId</td><td>A string indicating the Keyfactor Command GUID of the orchestrator that can re-enroll the certificate store.</td></tr>
<tr><td>Message</td><td>A string indicating the reason the certificate store cannot re-enroll, if applicable.</td></tr>
<tr><td>JobProperties</td><td>An array of key/value pairs for the unique parameters defined</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>for the certificate store type. The key is the name of the specific parameter from the certificate store type definition as returned in the JobProperties on the store type using the GET CertificateStoreTypes method and the value is the value that should be set for that parameter on a certificate in the certificate store. For example, for NetScaler, the key name that is optionally used to associate a certificate with a virtual server is NetscalerVserver and is returned by GET CertificateStoreTypes like so:
<code>"JobProperties": ["NetscalerVserver"]</code>
It can be seen in the Keyfactor Command Management Portal when editing the certificate store type in the field for Management Job Custom Fields.
The setting is referenced using the following format:
<code>"JobProperties": [
{"NetscalerVserver":"MyVirtualServerName"}]</code>
Note: The only built-in certificate store type that makes use of job properties that can be set on a certificate-by-certificate basis in the store is NetScaler. You may have custom certificate store types that make use of this functionality.
This field is optional.</td></tr>
<tr><td>CustomAliasAllowed</td><td>An integer indicating the option for a custom alias for this certificate store.
• 0—forbidden
• 1—optional
• 2—required</td></tr>
</table>
</td></tr>
<tr><td>SetNewPasswordAllowed</td><td>A Boolean that indicates whether the store password can be changed (true) or not (false).</td></tr>
<tr><td>Password</td><td>Note: Secret data is stored in the secrets table or a PAM provider and is not returned in responses.</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.9.3 POST Certificate Stores

The POST /CertificateStores method is used to create new certificate stores in Keyfactor Command. This method returns HTTP 200 OK on a success with details about the certificate store created.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: CertificateStoreManagement: *Modify*

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Table 253: POST Certificate Stores Input Parameters

Name	In	Description
ContainerId	Body	An integer indicating the ID of the certificate store's associated certificate store container, if applicable (see GET Certificate Store Containers on page 1212).
ClientMachine	Body	**Required**. The string value of the client machine. The value for this will vary depending on the certificate store type. For example, for a Java keystore or an F5 device, it is the hostname of the machine on which the store is located, but for an Amazon Web Services store, it is the FQDN of the Keyfactor Command Windows Orchestrator. See Adding or Modifying a Certificate Store on page 363 in the *Keyfactor Command Reference Guide* for more information.
Storepath	Body	**Required**. A string indicating the path to the certificate store on the target. The format for this path will vary depending on the certificate store type. For example, for a Java keystore, this will be a file path (e.g. /opt/myapp/store.jks), but for an F5 device, this will be a partition name on the device (e.g. Common). See Adding or Modifying a Certificate Store on page 363 in the *Keyfactor Command Reference Guide* for more information. The maximum number of characters supported in this field is 722.
CertStoreInventoryJobId	Body	A string indicating the GUID that identifies the inventory job for the certificate store in the Keyfactor Command database. This will be null if an inventory schedule is not set for the certificate store.
CertStoreType	Body	**Required**. An integer indicating the ID of the certificate store type, as defined in Keyfactor Command, for this certificate store. (0-Javakeystore,2-PEMFile, 3-F5SSLProfiles,4-IISRoots, 5-NetScaler, 6-IISPersonal, 7-F5WebServer, 8-IISRevoked, 9-F5WebServerREST, 10-F5SSLProfilesREST, 11-F5CABundlesREST, 100-AmazonWebServices, 101-FileTransferProtocol)
Approved	Body	A Boolean that indicates whether a certificate store is approved (true) or not (false). If a certificate store is approved, it can be used and updated. A certificate store that has been discovered using the discover feature but not yet marked as approved will be false here. The default for new stores created with this method is *true*.
CreateIfMissing	Body	A Boolean that indicates whether a new certificate store should be created with the information provided (true) or not (false). This option is only valid for Java keystores and any custom certificate store types you have defined to support this functionality. The default is *false*.
Properties	Body	**Required**. Some types of certificate stores have additional properties that are stored in this parameter. The data is stored in a series of, typically, key value pairs that define the property name and value (see GET Certificate Store Types on page 1242 for more information). As of Keyfactor Command v10, this parameter is used to store certificate store server usernames, server passwords, and the UseSSL flag. Built-in certificate stores that typically require configuration of certificate store server parameters include NetScaler and F5 stores. The legacy methods for managing certificate store server credentials have been deprecated but are retained for backwards compatiblity. For more information, see POST Certificate Stores Server on page 1165. When reading this field, the values are returned as simple key value pairs, with the values

Name	In	Description

		being individual values. When writing, the values are specified as objects, though they are typically single values.
		For example, on a GET request for a *PEM* store configured with a separate private key, the contents of this field might be:
		`"{ \"privateKeyPath\":\"/opt/app/mystore.key\", \"separatePrivateKey\":\"true\" }"`
		However, the syntax used when updating the properties sets the value as a key value pair using *value* as the key. For example, on a POST or PUT request for a *PEM* store configured with a separate private key, the contents of this field might be:
		`"{ \"privateKeyPath\":{\"value\":\"/opt/app/mystore.key\"}, \"separatePrivateKey\":{\"value\":\"true\"} }"`
		An example server properties parameter POST for an FTP or NetScaler store would contain:
		`"{ \"ServerUsername\":{\"value\":{\"SecretValue\":\"User_Name\"}}, \"ServerPassword\":{\"value\":{\"SecretValue\":\"Password\"}}, \"ServerUseSsl\":{\"value\":\"true\"} }"`
		An example server properties parameter POST for an FTP or NetScaler store with the username and password stored as PAM secrets would contain (where the Provider value—1 in this example—is the Id value from GET PAM Providers on page 1455):
		`"{ \"ServerUsername\":{\"value\":{\"Provider\":\"1\",\"Parameters\": {\"SecretId\":\"User_Name\"}}}, \"ServerPassword\":{\"value\":{\"Provider\":\"1\",\"Parameters\": {\"SecretId\":\"Password\"}}}, \"ServerUseSsl\":{\"value\":\"true\"} }"`
		Note: There are three standard properties that are used for any built-in certificate store types that require server credentials (e.g. F5):
		• ServerUsername
		• ServerPassword

Name	In	Description
		 • ServerUseSsl These replace the separate certificate store server records that existed in previous versions of Keyfactor Command. For legacy support, if credentials are not provided through store properties during creation or editing of a certificate store, Keyfactor Command will attempt to find a certificate store server record and copy the credentials from it into the store properties for future use.  **Tip:** Built-in stores that make use of this field include: • AWS stores use this field to store secured versions of the access key and secret. • F5 REST stores (all types) use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl) and primary node information (PrimaryNode, PrimaryNodeCheckRetryWaitSecs, PrimaryNodeCheckRetryMax) and F5 version (F5Version). • F5 SOAP stores (all types) use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl). • FTP stores use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl). • IIS stores (all types) use this field to store the UseSSL flag and the port for SMB communications. • Java keystores use this field to store type (ProviderType). • NetScaler stores use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl). • PEM stores use this field to store the path to the private key file, if defined, and the Boolean value indicating whether a separate private key path is defined.
AgentId	Body	**Required**. A string indicating the Keyfactor Command GUID of the orchestrator for this store.
AgentAssigned	Body	A Boolean that indicates whether there is an orchestrator assigned to this certificate store (true) or not (false). The default is *true*.
ContainerName	Body	A string indicating the name of the certificate store's associated container, if applicable.
InventorySchedule	Body	The inventory schedule for this certificate store. The following schedule types are supported:

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
<tr><td>Immediate</td><td>A Boolean that indicates a job scheduled to run immediately (true) or not (false).

Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as null.</td></tr>
<tr><td>Interval</td><td>A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Minutes</td><td>An integer indicating the number of minutes between each interval.</td></tr>
</table>
For example, every hour:
<pre>"Interval": {
   "Minutes": 60
}</pre></td></tr>
<tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, daily at 11:30 pm:
<pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre></td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>ExactlyOnce</td><td>A dictionary that indicates a job scheduled to run at the time specified with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, exactly once at 11:45 am:
<pre>"ExactlyOnce": {
   "Time": "2022-02-27T11:45:00Z"
}</pre>

Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as ExactlyOnce.</td></tr>
</table>

Note: Although the Swagger Example Value may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint.
</td></tr>
<tr><td>ReenrollmentStatus</td><td>Body</td><td>An array that indicates whether the certificate store can use the re-enrollment function with accompanying data about the re-enrollment job. The following reenrollment fields are supported:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Data</td><td>A Boolean that indicates whether the certificate store can use the re-enrollment function (true) or not (false).</td></tr>
<tr><td>AgentId</td><td>A string indicating the Keyfactor Command GUID of the orchestrator that can re-enroll the certificate store.</td></tr>
<tr><td>Message</td><td>A string indicating the reason the certificate store cannot re-enroll, if applicable.</td></tr>
<tr><td>JobProperties</td><td>An array of key/value pairs for the unique parameters defined</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>for the certificate store type. The key is the name of the specific parameter from the certificate store type definition as returned in the JobProperties on the store type using the GET CertificateStoreTypes method and the value is the value that should be set for that parameter on a certificate in the certificate store. For example, for NetScaler, the key name that is optionally used to associate a certificate with a virtual server is NetscalerVserver and is returned by GET CertificateStoreTypes like so:
<code>"JobProperties": ["NetscalerVserver"]</code>
It can be seen in the Keyfactor Command Management Portal when editing the certificate store type in the field for Management Job Custom Fields.
The setting is referenced using the following format:
<code>"JobProperties": [
{"NetscalerVserver":"MyVirtualServerName"}
]</code>
Note: The only built-in certificate store type that makes use of job properties that can be set on a certificate-by-certificate basis in the store is NetScaler. You may have custom certificate store types that make use of this functionality.
This field is optional.</td></tr>
<tr><td>CustomAliasAllowed</td><td>An integer indicating the option for a custom alias for this certificate store.
0—forbidden
1—optional
2—required</td></tr>
</table>
</td></tr>
<tr><td>SetNewPasswordAllowed</td><td>Body</td><td>A Boolean that indicates whether the store password can be changed (true) or not (false). The default is false.</td></tr>
<tr><td>Password</td><td>Body</td><td>An array indicating the source for and details of the credential information Keyfactor Command will use to access the certificates in a specific certificate store (the store password). This is different from credential information Keyfactor Command uses to access a certificate store server as a whole. The former (this setting) is typically used for Java keystores; the latter is typically used for certificates stores on NetScaler and F5 devices and set at the server level, not the certificate store level (see POST Certificate Stores Server on page 1165).</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
Certificate stores that require credentials support up to three possible credential options:

Use no store password.
This option is supported for Java keystores that would normally require a password, but can be configured with the no password option (see Value, below).
Store the credential information in the Keyfactor secrets table.
A Keyfactor secret is a user-defined password that is encrypted and stored securely in the Keyfactor Command database.
Load the credential information from a PAM provider.
See Privileged Access Management (PAM) on page 640 in the Keyfactor Command Reference Guide and PAM Providers on page 1439 for more information.

The possible values are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Value</td><td>A string—submitted as an object—indicating a password to be stored as a Keyfactor secret.

Tip: To set the no password option on a store, submit the password with a null value. For example:
<pre>"Password": {
   "Value": {null}
}</pre>To set the value to a string to be stored in the Keyfactor secrets table, include the password in quotes. For example:
<pre>"Password": {
   "Value": "MyVerySecurePassword"
}</pre></td></tr>
<tr><td>SecretTypeGuid</td><td>A string indicating the Keyfactor Command reference GUID for the type of credentials. This value is automatically set by Keyfactor Command.</td></tr>
<tr><td>InstanceId</td><td>The Keyfactor Command reference ID for the secret provider. If you are using a secret provider with an integer ID, this will be used. This value is automatically set by Keyfactor Command.</td></tr>
<tr><td>InstanceGuid</td><td>The Keyfactor Command reference GUID for the secret provider. If you are using a secret provider with a GUID ID, this will be used. This value is automatically set by Keyfactor Command.</td></tr>
<tr><td>ProviderType Para-</td><td>An array containing the values for the PAM provider types specified by ProviderTypeParams. The provider type parameter values include:</td></tr>
</table>
</td></tr>
</table>

Name	In	Description
		Name / **Description** meterValue-s **Name** / **Description** Id — The Keyfactor Command reference ID for the PAM provider type parameter. Value — The value set for the parameter (e.g. the name of the CyberArk folder where the protected object that stores the username or password resides). InstanceId — The Keyfactor Command reference ID for the PAM provider. If you are attaching to something with an integer Id, this will be used. InstanceGuid — The Keyfactor Command reference GUID for the PAM provider. If you are attaching to something with a GUID ID, this will be used. Provider — An array containing information about the provider. PAM provider details include: **Name** / **Description** Id — An integer indicating the Keyfactor Command reference ID for the PAM provider. Name — A string indicating the internal name for the PAM provider. Area — An integer indicating the area of Keyfactor Command the provider is used for. PAM providers generally have a value of 1, indicating they are used for certificate stores. ProviderType — An array containing details about the provider type for the provider, including:

Name	In	Description
		Name / **Description** **Name** / **Description** **Name** / **Description** **Name** / **Description** Id — A string indicating the Keyfactor Command reference GUID for the provider type. Name — A string that indicates the name of the provider type. Provider Type Params — An array of parameters that the provider type uses for data input in Keyfactor Command when creating new PAM provider and certificate store records. See below instance of *ProviderTypeParam* for details. Provider-Type — An array containing the values for

Name	In	Description
		Name / **Description** **Name** / **Description** **Name** / **Description** Para-mValues — the provider types specified by ProviderTypeParams. See the previous level of *Provider-TypeParamValues* for details. SecuredAre-aId — An integer indicating the Keyfactor Command reference ID for the certificate store container the PAM provider is associated with, if any. You can create a single PAM provider for each provider type (e.g. CyberArk), however, if you have opted to organize your certificate stores into containers, you will need to create multiple providers to match your container organization structure. The container field in the PAM provider definition is not required, but if one is supplied when creating a PAM provider, the PAM provider can only be used with certificate stores in the matching container. Likewise, a PAM provider defined with no container would be available for selection when setting passwords for any certificate store that also did not specify a container. A PAM provider configured in this way could be used across a variety of certificate stores (e.g. both JKS and F5) as long as they were not in containers.

Name	In	Description
		Name / **Description** **Name**: Provider-Type Param **Description**: An array of parameters that the provider type uses for data input in Keyfactor Command when creating new PAM provider and certificate store records. PAM provider type parameters include: **Name** / **Description** Id — An integer indicating the Keyfactor Command reference ID for the PAM provider type parameter. Name — A string indicating the internal name for the PAM provider type parameter. DisplayName — A string indicating the display name for the PAM provider type parameter. For parameters with an InstanceLevel of *false*, this name appears on the PAM provider dialog for the parameter when a user creates a new PAM provider. For parameters with an InstanceLevel of *true*, this name appears on the Server dialog for the parameter when a user creates a new PAM provider. DataType — An integer indicating the data type for the parameter. Possible values are: • 1 = String • 2 = Secret InstanceLevel — A Boolean that sets whether the parameter is used to define the

Name	In	Description
		Name / **Description** **Name** / **Description** **Name** / **Description** underlying PAM provider (false) or a field that needs to be set to a value when configuring a certificate store to use the PAM provider (true). For an example, see GET PAM Providers on page 1455. Provider-Type: An array containing details for the provider type. **Name** / **Description-tion** Id: A string indicating the Keyfactor Command reference GUID for the PAM provider type parameter. Name: A string indicating the internal name for the PAM

</table>
</td></tr>
</table>

Table 254: POST Certificate Stores Response Data

Name	Description
Id	A string indicating the GUID of the certificate store within Keyfactor Command. This ID is automatically set by Keyfactor Command.
ContainerId	An integer indicating the ID of the certificate store's associated certificate store container, if applicable (see GET Certificate Store Containers on page 1212).
ClientMachine	The string value of the client machine. The value for this will vary depending on the certificate store type. For example, for a Java keystore or an F5 device, it is the hostname of the machine on which the store is located, but for an Amazon Web Services store, it is the FQDN of the Keyfactor Command Windows Orchestrator. See Adding or Modifying a Certificate Store on page 363 in the *Keyfactor Command Reference Guide* for more information.
Storepath	A string indicating the path to the certificate store on the target. The format for this path will vary depending on the certificate store type. For example, for a Java keystore, this will be a file path (e.g. /opt/myapp/store.jks), but for an F5 device, this will be a partition name on the device (e.g. Common). See Adding or Modifying a Certificate Store on page 363 in the *Keyfactor Command Reference Guide* for more information. The maximum number of characters supported in this field is 722.
CertStoreInventoryJobId	A string indicating the GUID that identifies the inventory job for the certificate store in the Keyfactor Command database. This will be null if an inventory schedule is not set for the certificate store.
CertStoreType	An integer indicating the ID of the certificate store type, as defined in Keyfactor Command, for this certificate store. (0-Javakeystore,2-PEMFile, 3-F5SSLProfiles,4-IISRoots, 5-NetScaler, 6-IISPersonal, 7-F5WebServer, 8-IISRevoked, 9-F5WebServerREST, 10-F5SSLProfilesREST, 11-F5CABundlesREST, 100-AmazonWebServices, 101-FileTransferProtocol)
Approved	A Boolean that indicates whether a certificate store is approved (true) or not (false). If a certificate store is approved, it can be used and updated. A certificate store that has been discovered using the discover feature but not yet marked as approved will be false here.
CreateIfMissing	A Boolean that indicates whether a new certificate store should be created with the information provided (true) or not (false). This option is only valid for Java keystores and any custom certificate store types you have defined to support this functionality.
Properties	Some types of certificate stores have additional properties that are stored in this parameter. The data is stored in a series of, typically, key value pairs that define the property name and value (see GET Certificate Store Types on page 1242 for more information). As of Keyfactor Command v10, this parameter is used to store certificate store server usernames, server passwords, and the UseSSL flag. Built-in certificate stores that typically require configuration of certificate store server parameters include NetScaler and F5 stores. The legacy methods for managing certificate store server credentials have been deprecated but are retained for backwards compatiblity. For more information, see POST Certificate Stores Server

Name	Description

	on page 1165.
	When reading this field, the values are returned as simple key value pairs, with the values being individual values. When writing, the values are specified as objects, though they are typically single values.
	For example, on a GET request for a *PEM* store configured with a separate private key, the contents of this field might be:
	`"{ \"privateKeyPath\":\"/opt/app/mystore.key\", \"separatePrivateKey\":\"true\" }"`
	However, the syntax used when updating the properties sets the value as a key value pair using *value* as the key. For example, on a POST or PUT request for a *PEM* store configured with a separate private key, the contents of this field might be:
	`"{ \"privateKeyPath\":{\"value\":\"/opt/app/mystore.key\"}, \"separatePrivateKey\":{\"value\":\"true\"} }"`
	An example server properties parameter POST for an FTP or NetScaler store would contain:
	`"{ \"ServerUsername\":{\"value\":{\"SecretValue\":\"User_Name\"}}, \"ServerPassword\":{\"value\":{\"SecretValue\":\"Password\"}}, \"ServerUseSsl\":{\"value\":\"true\"} }"`
	An example server properties parameter POST for an FTP or NetScaler store with the username and password stored as PAM secrets would contain (where the Provider value—1 in this example—is the Id value from GET PAM Providers on page 1455):
	`"{ \"ServerUsername\":{\"value\":{\"Provider\":\"1\",\"Parameters\": {\"SecretId\":\"User_Name\"}}}, \"ServerPassword\":{\"value\":{\"Provider\":\"1\",\"Parameters\": {\"SecretId\":\"Password\"}}}, \"ServerUseSsl\":{\"value\":\"true\"} }"`
	Note: There are three standard properties that are used for any built-in certificate store types that require server credentials (e.g. F5):

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>

ServerUsername
ServerPassword
ServerUseSsl

These replace the separate certificate store server records that existed in previous versions of Keyfactor Command. For legacy support, if credentials are not provided through store properties during creation or editing of a certificate store, Keyfactor Command will attempt to find a certificate store server record and copy the credentials from it into the store properties for future use.

Tip: Built-in stores that make use of this field include:

AWS stores use this field to store secured versions of the access key and secret.
F5 REST stores (all types) use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl) and primary node information (PrimaryNode, PrimaryNodeCheckRetryWaitSecs, PrimaryNodeCheckRetryMax) and F5 version (F5Version).
F5 SOAP stores (all types) use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl).
FTP stores use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl).
IIS stores (all types) use this field to store the UseSSL flag and the port for SMB communications.
Java keystores use this field to store type (ProviderType).
NetScaler stores use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl).
PEM stores use this field to store the path to the private key file, if defined, and the Boolean value indicating whether a separate private key path is defined.

</td></tr>
<tr><td>AgentId</td><td>A string indicating the Keyfactor Command GUID of the orchestrator for this store.</td></tr>
<tr><td>AgentAssigned</td><td>A Boolean that indicates whether there is an orchestrator assigned to this certificate store (true) or not (false).</td></tr>
<tr><td>ContainerName</td><td>A string indicating the name of the certificate store's associated container, if applicable.</td></tr>
<tr><td>InventorySchedule</td><td>The inventory schedule for this certificate store. The following schedule types are supported:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
</table>
</td></tr>
</table>

Name	Description

Name	Description
Immediate	A Boolean that indicates a job scheduled to run immediately (true) or not (false). **Tip:** In some instances, jobs initially scheduled as *Immediate* will appear on a GET as *null*.
Interval	A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.

Name	Description
Minutes	An integer indicating the number of minutes between each interval.

For example, every hour:

```
"Interval": {
   "Minutes": 60
}
```

Name	Description
Daily	A dictionary that indicates a job scheduled to run every day at the same time with the parameter:

Name	Description
Time	The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).

For example, daily at 11:30 pm:

```
"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}
```

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>ExactlyOnce</td><td>A dictionary that indicates a job scheduled to run at the time specified with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, exactly once at 11:45 am:
<pre>"ExactlyOnce": {
   "Time": "2022-02-27T11:45:00Z"
}</pre>
Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as ExactlyOnce.</td></tr>
</table>
Note: Although the Swagger Example Value may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint.
</td></tr>
<tr><td>ReenrollmentStatus</td><td>An array that indicates whether the certificate store can use the re-enrollment function with accompanying data about the re-enrollment job. The following reenrollment fields are supported:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Data</td><td>A Boolean that indicates whether the certificate store can use the re-enrollment function (true) or not (false).</td></tr>
<tr><td>AgentId</td><td>A string indicating the Keyfactor Command GUID of the orchestrator that can re-enroll the certificate store.</td></tr>
<tr><td>Message</td><td>A string indicating the reason the certificate store cannot re-enroll, if applicable.</td></tr>
<tr><td>JobProperties</td><td>An array of key/value pairs for the unique parameters defined</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>for the certificate store type. The key is the name of the specific parameter from the certificate store type definition as returned in the JobProperties on the store type using the GET CertificateStoreTypes method and the value is the value that should be set for that parameter on a certificate in the certificate store. For example, for NetScaler, the key name that is optionally used to associate a certificate with a virtual server is NetscalerVserver and is returned by GET CertificateStoreTypes like so:
<code>"JobProperties": ["NetscalerVserver"]</code>
It can be seen in the Keyfactor Command Management Portal when editing the certificate store type in the field for Management Job Custom Fields.
The setting is referenced using the following format:
<code>"JobProperties": [
{"NetscalerVserver":"MyVirtualServerName"}]</code>
Note: The only built-in certificate store type that makes use of job properties that can be set on a certificate-by-certificate basis in the store is NetScaler. You may have custom certificate store types that make use of this functionality.
This field is optional.</td></tr>
<tr><td>CustomAliasAllowed</td><td>An integer indicating the option for a custom alias for this certificate store.
0—forbidden
1—optional
2—required</td></tr>
</table>
</td></tr>
<tr><td>SetNewPasswordAllowed</td><td>A Boolean that indicates whether the store password can be changed (true) or not (false).</td></tr>
<tr><td>Password</td><td>Note: Secret data is stored in the secrets table or a PAM provider and is not returned in responses.</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.9.4 PUT Certificate Stores

The PUT /CertificateStores method is used to update an existing certificate store in Keyfactor Command. This method returns HTTP 200 OK on a success with a message body containing the certificate store.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateStoreManagement: *Modify*

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Warning: Any previously populated fields that are not submitted with their full existing data using this method will be cleared of their existing data. When using this method, you should first do a GET to retrieve all the values for the record you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing.

Table 255: PUT Certificate Stores Input Parameters

Name	In	Description
Id	Body	A string indicating the GUID of the certificate store within Keyfactor Command. This ID is automatically set by Keyfactor Command.
ContainerId	Body	An integer indicating the ID of the certificate store's associated certificate store container, if applicable (see GET Certificate Store Containers on page 1212).
ClientMachine	Body	**Required**. The string value of the client machine. The value for this will vary depending on the certificate store type. For example, for a Java keystore or an F5 device, it is the hostname of the machine on which the store is located, but for an Amazon Web Services store, it is the FQDN of the Keyfactor Command Windows Orchestrator. See Adding or Modifying a Certificate Store on page 363 in the *Keyfactor Command Reference Guide* for more information.
Storepath	Body	**Required**. A string indicating the path to the certificate store on the target. The format for this path will vary depending on the certificate store type. For example, for a Java keystore, this will be a file path (e.g. /opt/myapp/store.jks), but for an F5 device, this will be a partition name on the device (e.g. Common). See Adding or Modifying a Certificate Store on page 363 in the *Keyfactor Command Reference Guide* for more information. The maximum number of characters supported in this field is 722.
CertStoreInventoryJobId	Body	A string indicating the GUID that identifies the inventory job for the certificate store in the Keyfactor Command database. This will be null if an inventory schedule is not set for the certificate store.
CertStoreType	Body	**Required**. An integer indicating the ID of the certificate store type, as defined in Keyfactor Command, for this certificate store. (0-Javakeystore,2-PEMFile, 3-F5SSLProfiles,4-IISRoots, 5-NetScaler, 6-IISPersonal, 7-F5WebServer, 8-IISRevoked, 9-F5WebServerREST, 10-F5SSLProfilesREST, 11-F5CABundlesREST, 100-AmazonWebServices, 101-FileTransferProtocol)
Approved	Body	A Boolean that indicates whether a certificate store is approved (true) or not (false). If a certificate store is approved, it can be used and updated. A certificate store that has been discovered using the discover feature but not yet marked as approved will be false here. The default for new stores created with this method is *true*.
CreateIfMissing	Body	A Boolean that indicates whether a new certificate store should be created with the information provided (true) or not (false). This option is only valid for Java keystores and any custom certificate store types you have defined to support this functionality. The default is *false*.
Properties	Body	**Required**. Some types of certificate stores have additional properties that are stored in this parameter. The data is stored in a series of, typically, key value pairs that define the property name and value (see GET Certificate Store Types on page 1242 for more information). As of Keyfactor Command v10, this parameter is used to store certificate store server usernames, server passwords, and the UseSSL flag. Built-in certificate stores that typically require configuration of certificate store server parameters include NetScaler and F5 stores. The legacy methods for managing certificate store server credentials have been deprecated but

Name	In	Description

		are retained for backwards compatiblity. For more information, see POST Certificate Stores Server on page 1165.
		When reading this field, the values are returned as simple key value pairs, with the values being individual values. When writing, the values are specified as objects, though they are typically single values.
		For example, on a GET request for a *PEM* store configured with a separate private key, the contents of this field might be:
		`"{ \"privateKeyPath\":\"/opt/app/mystore.key\", \"separatePrivateKey\":\"true\" }"`
		However, the syntax used when updating the properties sets the value as a key value pair using *value* as the key. For example, on a POST or PUT request for a *PEM* store configured with a separate private key, the contents of this field might be:
		`"{ \"privateKeyPath\":{\"value\":\"/opt/app/mystore.key\"}, \"separatePrivateKey\":{\"value\":\"true\"} }"`
		An example server properties parameter POST for an FTP or NetScaler store would contain:
		`"{ \"ServerUsername\":{\"value\":{\"SecretValue\":\"User_Name\"}}, \"ServerPassword\":{\"value\":{\"SecretValue\":\"Password\"}}, \"ServerUseSsl\":{\"value\":\"true\"} }"`
		An example server properties parameter POST for an FTP or NetScaler store with the username and password stored as PAM secrets would contain (where the Provider value—1 in this example—is the Id value from GET PAM Providers on page 1455):
		`"{ \"ServerUsername\":{\"value\":{\"Provider\":\"1\",\"Parameters\": {\"SecretId\":\"User_Name\"}}}, \"ServerPassword\":{\"value\":{\"Provider\":\"1\",\"Parameters\": {\"SecretId\":\"Password\"}}}, \"ServerUseSsl\":{\"value\":\"true\"} }"`
		Note: There are three standard properties that are used for any built-in certificate

Name	In	Description
		store types that require server credentials (e.g. F5): • ServerUsername • ServerPassword • ServerUseSsl These replace the separate certificate store server records that existed in previous versions of Keyfactor Command. For legacy support, if credentials are not provided through store properties during creation or editing of a certificate store, Keyfactor Command will attempt to find a certificate store server record and copy the credentials from it into the store properties for future use. **Tip:** Built-in stores that make use of this field include: • AWS stores use this field to store secured versions of the access key and secret. • F5 REST stores (all types) use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl) and primary node information (PrimaryNode, PrimaryNodeCheckRetryWaitSecs, PrimaryNodeCheckRetryMax) and F5 version (F5Version). • F5 SOAP stores (all types) use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl). • FTP stores use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl). • IIS stores (all types) use this field to store the UseSSL flag and the port for SMB communications. • Java keystores use this field to store type (ProviderType). • NetScaler stores use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl). • PEM stores use this field to store the path to the private key file, if defined, and the Boolean value indicating whether a separate private key path is defined.
AgentId	Body	**Required**. A string indicating the Keyfactor Command GUID of the orchestrator for this store.
AgentAssigned	Body	A Boolean that indicates whether there is an orchestrator assigned to this certificate store (true) or not (false). The default is *true*.
ContainerName	Body	A string indicating the name of the certificate store's associated container, if applicable.
InventorySchedule	Body	The inventory schedule for this certificate store. The following schedule types are supported:

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>

</td></tr>
<tr><td>SetNewPasswordAllowed</td><td>Body</td><td>A Boolean that indicates whether the store password can be changed (true) or not (false). The default is false.</td></tr>
<tr><td>Password</td><td>Body</td><td>An array indicating the source for and details of the credential information Keyfactor Command will use to access the certificates in a specific certificate store (the store password). This is different from credential information Keyfactor Command uses to access a certificate store server as a whole. The former (this setting) is typically used for Java keystores; the latter is typically used for certificates stores on NetScaler and F5 devices and set at the server level, not the certificate store level (see POST Certificate Stores Server on page 1165).</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
Certificate stores that require credentials support up to three possible credential options:

Use no store password.
This option is supported for Java keystores that would normally require a password, but can be configured with the no password option (see Value, below).
Store the credential information in the Keyfactor secrets table.
A Keyfactor secret is a user-defined password that is encrypted and stored securely in the Keyfactor Command database.
Load the credential information from a PAM provider.
See Privileged Access Management (PAM) on page 640 in the Keyfactor Command Reference Guide and PAM Providers on page 1439 for more information.

The possible values are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Value</td><td>A string—submitted as an object—indicating a password to be stored as a Keyfactor secret.

Tip: To set the no password option on a store, submit the password with a null value. For example:
<pre>"Password": {
   "Value": {null}
}</pre>To set the value to a string to be stored in the Keyfactor secrets table, include the password in quotes. For example:
<pre>"Password": {
   "Value": "MyVerySecurePassword"
}</pre></td></tr>
<tr><td>SecretTypeGuid</td><td>A string indicating the Keyfactor Command reference GUID for the type of credentials. This value is automatically set by Keyfactor Command.</td></tr>
<tr><td>InstanceId</td><td>The Keyfactor Command reference ID for the secret provider. If you are using a secret provider with an integer ID, this will be used. This value is automatically set by Keyfactor Command.</td></tr>
<tr><td>InstanceGuid</td><td>The Keyfactor Command reference GUID for the secret provider. If you are using a secret provider with a GUID ID, this will be used. This value is automatically set by Keyfactor Command.</td></tr>
<tr><td>ProviderType Para-</td><td>An array containing the values for the PAM provider types specified by ProviderTypeParams. The provider type parameter values include:</td></tr>
</table>
</td></tr>
</table>

Name	In	Description
		Name / **Description** meterValue-s **Name** / **Description** Id — The Keyfactor Command reference ID for the PAM provider type parameter. Value — The value set for the parameter (e.g. the name of the CyberArk folder where the protected object that stores the username or password resides). InstanceId — The Keyfactor Command reference ID for the PAM provider. If you are attaching to something with an integer Id, this will be used. InstanceGuid — The Keyfactor Command reference GUID for the PAM provider. If you are attaching to something with a GUID ID, this will be used. Provider — An array containing information about the provider. PAM provider details include: **Name** / **Description** Id — An integer indicating the Keyfactor Command reference ID for the PAM provider. Name — A string indicating the internal name for the PAM provider. Area — An integer indicating the area of Keyfactor Command the provider is used for. PAM providers generally have a value of 1, indicating they are used for certificate stores. ProviderType — An array containing details about the provider type for the provider, including:

Name	In	Description
		Name / **Description** **Name** / **Description** **Name** / **Description** **Name** / **Description** Id — A string indicating the Keyfactor Command reference GUID for the provider type. Name — A string that indicates the name of the provider type. Provider Type Params — An array of parameters that the provider type uses for data input in Keyfactor Command when creating new PAM provider and certificate store records. See below instance of *ProviderTypeParam* for details. Provider-Type — An array containing the values for

Name	In	Description
		Name / **Description** **Name** / **Description** **Name** / **Description** Para-mValues — the provider types specified by ProviderTypeParams. See the previous level of *Provider-TypeParamValues* for details. SecuredAre-aId — An integer indicating the Keyfactor Command reference ID for the certificate store container the PAM provider is associated with, if any. You can create a single PAM provider for each provider type (e.g. CyberArk), however, if you have opted to organize your certificate stores into containers, you will need to create multiple providers to match your container organization structure. The container field in the PAM provider definition is not required, but if one is supplied when creating a PAM provider, the PAM provider can only be used with certificate stores in the matching container. Likewise, a PAM provider defined with no container would be available for selection when setting passwords for any certificate store that also did not specify a container. A PAM provider configured in this way could be used across a variety of certificate stores (e.g. both JKS and F5) as long as they were not in containers.

Name	In	Description
		Name / **Description** **Name**: Provider-Type Param **Description**: An array of parameters that the provider type uses for data input in Keyfactor Command when creating new PAM provider and certificate store records. PAM provider type parameters include: **Name** / **Description** Id — An integer indicating the Keyfactor Command reference ID for the PAM provider type parameter. Name — A string indicating the internal name for the PAM provider type parameter. DisplayName — A string indicating the display name for the PAM provider type parameter. For parameters with an InstanceLevel of *false*, this name appears on the PAM provider dialog for the parameter when a user creates a new PAM provider. For parameters with an InstanceLevel of *true*, this name appears on the Server dialog for the parameter when a user creates a new PAM provider. DataType — An integer indicating the data type for the parameter. Possible values are: • 1 = String • 2 = Secret InstanceLevel — A Boolean that sets whether the parameter is used to define the

Name	In	Description
		Name / **Description** **Name** / **Description** **Name** / **Description** underlying PAM provider (false) or a field that needs to be set to a value when configuring a certificate store to use the PAM provider (true). For an example, see GET PAM Providers on page 1455. Provider-Type: An array containing details for the provider type. **Name** / **Descrip-tion** Id: A string indicating the Keyfactor Command reference GUID for the PAM provider type para-meter. Name: A string indicating the internal name for the PAM

</td></tr>
</table>

Table 256: PUT Certificate Stores Response Data

Name	Description
Id	A string indicating the GUID of the certificate store within Keyfactor Command. This ID is automatically set by Keyfactor Command.
ContainerId	An integer indicating the ID of the certificate store's associated certificate store container, if applicable (see GET Certificate Store Containers on page 1212).
ClientMachine	The string value of the client machine. The value for this will vary depending on the certificate store type. For example, for a Java keystore or an F5 device, it is the hostname of the machine on which the store is located, but for an Amazon Web Services store, it is the FQDN of the Keyfactor Command Windows Orchestrator. See Adding or Modifying a Certificate Store on page 363 in the *Keyfactor Command Reference Guide* for more information.
Storepath	A string indicating the path to the certificate store on the target. The format for this path will vary depending on the certificate store type. For example, for a Java keystore, this will be a file path (e.g. /opt/myapp/store.jks), but for an F5 device, this will be a partition name on the device (e.g. Common). See Adding or Modifying a Certificate Store on page 363 in the *Keyfactor Command Reference Guide* for more information. The maximum number of characters supported in this field is 722.
CertStoreInventoryJobId	A string indicating the GUID that identifies the inventory job for the certificate store in the Keyfactor Command database. This will be null if an inventory schedule is not set for the certificate store.
CertStoreType	An integer indicating the ID of the certificate store type, as defined in Keyfactor Command, for this certificate store. (0-Javakeystore,2-PEMFile, 3-F5SSLProfiles,4-IISRoots, 5-NetScaler, 6-IISPersonal, 7-F5WebServer, 8-IISRevoked, 9-F5WebServerREST, 10-F5SSLProfilesREST, 11-F5CABundlesREST, 100-AmazonWebServices, 101-FileTransferProtocol)
Approved	A Boolean that indicates whether a certificate store is approved (true) or not (false). If a certificate store is approved, it can be used and updated. A certificate store that has been discovered using the discover feature but not yet marked as approved will be false here.
CreateIfMissing	A Boolean that indicates whether a new certificate store should be created with the information provided (true) or not (false). This option is only valid for Java keystores and any custom certificate store types you have defined to support this functionality.
Properties	Some types of certificate stores have additional properties that are stored in this parameter. The data is stored in a series of, typically, key value pairs that define the property name and value (see GET Certificate Store Types on page 1242 for more information). As of Keyfactor Command v10, this parameter is used to store certificate store server usernames, server passwords, and the UseSSL flag. Built-in certificate stores that typically require configuration of certificate store server parameters include NetScaler and F5 stores. The legacy methods for managing certificate store server credentials have been deprecated but are retained for backwards compatiblity. For more information, see POST Certificate Stores Server

Name	Description

	on page 1165.
	When reading this field, the values are returned as simple key value pairs, with the values being individual values. When writing, the values are specified as objects, though they are typically single values.
	For example, on a GET request for a *PEM* store configured with a separate private key, the contents of this field might be:
	`"{ \"privateKeyPath\":\"/opt/app/mystore.key\", \"separatePrivateKey\":\"true\" }"`
	However, the syntax used when updating the properties sets the value as a key value pair using *value* as the key. For example, on a POST or PUT request for a *PEM* store configured with a separate private key, the contents of this field might be:
	`"{ \"privateKeyPath\":{\"value\":\"/opt/app/mystore.key\"}, \"separatePrivateKey\":{\"value\":\"true\"} }"`
	An example server properties parameter POST for an FTP or NetScaler store would contain:
	`"{ \"ServerUsername\":{\"value\":{\"SecretValue\":\"User_Name\"}}, \"ServerPassword\":{\"value\":{\"SecretValue\":\"Password\"}}, \"ServerUseSsl\":{\"value\":\"true\"} }"`
	An example server properties parameter POST for an FTP or NetScaler store with the username and password stored as PAM secrets would contain (where the Provider value—1 in this example—is the Id value from GET PAM Providers on page 1455):
	`"{ \"ServerUsername\":{\"value\":{\"Provider\":\"1\",\"Parameters\": {\"SecretId\":\"User_Name\"}}}, \"ServerPassword\":{\"value\":{\"Provider\":\"1\",\"Parameters\": {\"SecretId\":\"Password\"}}}, \"ServerUseSsl\":{\"value\":\"true\"} }"`
	Note: There are three standard properties that are used for any built-in certificate store types that require server credentials (e.g. F5):

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>

ServerUsername
ServerPassword
ServerUseSsl

These replace the separate certificate store server records that existed in previous versions of Keyfactor Command. For legacy support, if credentials are not provided through store properties during creation or editing of a certificate store, Keyfactor Command will attempt to find a certificate store server record and copy the credentials from it into the store properties for future use.

Tip: Built-in stores that make use of this field include:

AWS stores use this field to store secured versions of the access key and secret.
F5 REST stores (all types) use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl) and primary node information (PrimaryNode, PrimaryNodeCheckRetryWaitSecs, PrimaryNodeCheckRetryMax) and F5 version (F5Version).
F5 SOAP stores (all types) use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl).
FTP stores use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl).
IIS stores (all types) use this field to store the UseSSL flag and the port for SMB communications.
Java keystores use this field to store type (ProviderType).
NetScaler stores use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl).
PEM stores use this field to store the path to the private key file, if defined, and the Boolean value indicating whether a separate private key path is defined.

</td></tr>
<tr><td>AgentId</td><td>A string indicating the Keyfactor Command GUID of the orchestrator for this store.</td></tr>
<tr><td>AgentAssigned</td><td>A Boolean that indicates whether there is an orchestrator assigned to this certificate store (true) or not (false).</td></tr>
<tr><td>ContainerName</td><td>A string indicating the name of the certificate store's associated container, if applicable.</td></tr>
<tr><td>InventorySchedule</td><td>The inventory schedule for this certificate store. The following schedule types are supported:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Immediate</td><td>A Boolean that indicates a job scheduled to run immediately (true) or not (false).

  Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as null.</td></tr>
<tr><td>Interval</td><td>A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Minutes</td><td>An integer indicating the number of minutes between each interval.</td></tr>
</table>

For example, every hour:

<pre>"Interval": {
   "Minutes": 60
}</pre></td></tr>
<tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>

For example, daily at 11:30 pm:

<pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre></td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>ExactlyOnce</td><td>A dictionary that indicates a job scheduled to run at the time specified with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, exactly once at 11:45 am:
<pre>"ExactlyOnce": {
   "Time": "2022-02-27T11:45:00Z"
}</pre>
Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as ExactlyOnce.</td></tr>
</table>
Note: Although the Swagger Example Value may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint.
</td></tr>
<tr><td>ReenrollmentStatus</td><td>An array that indicates whether the certificate store can use the re-enrollment function with accompanying data about the re-enrollment job. The following reenrollment fields are supported:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Data</td><td>A Boolean that indicates whether the certificate store can use the re-enrollment function (true) or not (false).</td></tr>
<tr><td>AgentId</td><td>A string indicating the Keyfactor Command GUID of the orchestrator that can re-enroll the certificate store.</td></tr>
<tr><td>Message</td><td>A string indicating the reason the certificate store cannot re-enroll, if applicable.</td></tr>
<tr><td>JobProperties</td><td>An array of key/value pairs for the unique parameters defined</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>for the certificate store type. The key is the name of the specific parameter from the certificate store type definition as returned in the JobProperties on the store type using the GET CertificateStoreTypes method and the value is the value that should be set for that parameter on a certificate in the certificate store. For example, for NetScaler, the key name that is optionally used to associate a certificate with a virtual server is NetscalerVserver and is returned by GET CertificateStoreTypes like so:
<code>"JobProperties": ["NetscalerVserver"]</code>
It can be seen in the Keyfactor Command Management Portal when editing the certificate store type in the field for Management Job Custom Fields.
The setting is referenced using the following format:
<code>"JobProperties": [
{"NetscalerVserver":"MyVirtualServerName"}]</code>
Note: The only built-in certificate store type that makes use of job properties that can be set on a certificate-by-certificate basis in the store is NetScaler. You may have custom certificate store types that make use of this functionality.
This field is optional.</td></tr>
<tr><td>CustomAliasAllowed</td><td>An integer indicating the option for a custom alias for this certificate store.
0—forbidden
1—optional
2—required</td></tr>
</table>
</td></tr>
<tr><td>SetNewPasswordAllowed</td><td>A Boolean that indicates whether the store password can be changed (true) or not (false).</td></tr>
<tr><td>Password</td><td>Note: Secret data is stored in the secrets table or a PAM provider and is not returned in responses.</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.9.5 DELETE Certificate Stores ID

The DELETE /CertificateStores/{id} method is used to delete an existing certificate store with the specified GUID. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateStoreManagement: *Modify*

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Table 257: DELETE Certificate Stores Input Parameters

Name	In	Description
id	Path	**Required**. A string indicating the GUID of the certificate store to delete. Use the *GET /CertificateStores* method (see GET Certificate Stores on page 1100) to retrieve a list of all the certificate stores to determine the certificate store GUID.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.9.6 GET Certificate Stores ID

The GET /CertificateStores/{id} method is used to return details for the certificate store with the specified ID. This method returns HTTP 200 OK on a success with a message body containing certificate store details.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateStoreManagement: *Read*

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Table 258: GET Certificate Stores {id} Input Parameters

Name	In	Description
id	Path	**Required**. A string indicating the GUID of the certificate store within Keyfactor Command.

Table 259: GET Certificate Stores {id} Response Data

Name	Description
Id	A string indicating the GUID of the certificate store within Keyfactor Command. This ID is automatically set by Keyfactor Command.
ContainerId	An integer indicating the ID of the certificate store's associated certificate store container, if applicable (see GET Certificate Store Containers on page 1212).
ClientMachine	The string value of the client machine. The value for this will vary depending on the certificate store type. For example, for a Java keystore or an F5 device, it is the hostname of the machine on which the store is located, but for an Amazon Web Services store, it is the FQDN of the Keyfactor Command Windows Orchestrator. See Adding or Modifying a Certificate Store on page 363 in the *Keyfactor Command Reference Guide* for more information.
Storepath	A string indicating the path to the certificate store on the target. The format for this path will vary depending on the certificate store type. For example, for a Java keystore, this will be a file path (e.g. /opt/myapp/store.jks), but for an F5 device, this will be a partition name on the device (e.g. Common). See Adding or Modifying a Certificate Store on page 363 in the *Keyfactor Command Reference Guide* for more information. The maximum number of characters supported in this field is 722.
CertStoreInventoryJobId	A string indicating the GUID that identifies the inventory job for the certificate store in the Keyfactor Command database. This will be null if an inventory schedule is not set for the certificate store.
CertStoreType	An integer indicating the ID of the certificate store type, as defined in Keyfactor Command, for this certificate store. (0-Javakeystore,2-PEMFile, 3-F5SSLProfiles,4-IISRoots, 5-NetScaler, 6-IISPersonal, 7-F5WebServer, 8-IISRevoked, 9-F5WebServerREST, 10-F5SSLProfilesREST, 11-F5CABundlesREST, 100-AmazonWebServices, 101-FileTransferProtocol)
Approved	A Boolean that indicates whether a certificate store is approved (true) or not (false). If a certificate store is approved, it can be used and updated. A certificate store that has been discovered using the discover feature but not yet marked as approved will be false here.
CreateIfMissing	A Boolean that indicates whether a new certificate store should be created with the information provided (true) or not (false). This option is only valid for Java keystores and any custom certificate store types you have defined to support this functionality.
Properties	Some types of certificate stores have additional properties that are stored in this parameter. The data is stored in a series of, typically, key value pairs that define the property name and value (see GET Certificate Store Types on page 1242 for more information). As of Keyfactor Command v10, this parameter is used to store certificate store server usernames, server passwords, and the UseSSL flag. Built-in certificate stores that typically require configuration of certificate store server parameters include NetScaler and F5 stores. The legacy methods for managing certificate store server credentials have been deprecated but are retained for backwards compatiblity. For more information, see POST Certificate Stores Server on page 1165. When reading this field, the values are returned as simple key value pairs, with the values being individual values. When writing, the values are specified as objects, though they are typically single

Name	Description

	values.
	For example, on a GET request for a *PEM* store configured with a separate private key, the contents of this field might be:
	`"{ \"privateKeyPath\":\"/opt/app/mystore.key\", \"separatePrivateKey\":\"true\" }"`
	However, the syntax used when updating the properties sets the value as a key value pair using *value* as the key. For example, on a POST or PUT request for a *PEM* store configured with a separate private key, the contents of this field might be:
	`"{ \"privateKeyPath\":{\"value\":\"/opt/app/mystore.key\"}, \"separatePrivateKey\":{\"value\":\"true\"} }"`
	An example server properties parameter POST for an FTP or NetScaler store would contain:
	`"{ \"ServerUsername\":{\"value\":{\"SecretValue\":\"User_Name\"}}, \"ServerPassword\":{\"value\":{\"SecretValue\":\"Password\"}}, \"ServerUseSsl\":{\"value\":\"true\"} }"`
	An example server properties parameter POST for an FTP or NetScaler store with the username and password stored as PAM secrets would contain (where the Provider value—1 in this example—is the Id value from GET PAM Providers on page 1455):
	`"{ \"ServerUsername\":{\"value\":{\"Provider\":\"1\",\"Parameters\": {\"SecretId\":\"User_Name\"}}}, \"ServerPassword\":{\"value\":{\"Provider\":\"1\",\"Parameters\": {\"SecretId\":\"Password\"}}}, \"ServerUseSsl\":{\"value\":\"true\"} }"`
	Note: There are three standard properties that are used for any built-in certificate store types that require server credentials (e.g. F5):
	• ServerUsername
	• ServerPassword
	• ServerUseSsl

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
These replace the separate certificate store server records that existed in previous versions of Keyfactor Command. For legacy support, if credentials are not provided through store properties during creation or editing of a certificate store, Keyfactor Command will attempt to find a certificate store server record and copy the credentials from it into the store properties for future use.
Tip: Built-in stores that make use of this field include:

AWS stores use this field to store secured versions of the access key and secret.
F5 REST stores (all types) use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl) and primary node information (PrimaryNode, PrimaryNodeCheckRetryWaitSecs, PrimaryNodeCheckRetryMax) and F5 version (F5Version).
F5 SOAP stores (all types) use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl).
FTP stores use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl).
IIS stores (all types) use this field to store the UseSSL flag and the port for SMB communications.
Java keystores use this field to store type (ProviderType).
NetScaler stores use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl).
PEM stores use this field to store the path to the private key file, if defined, and the Boolean value indicating whether a separate private key path is defined.

• 1—optional
• 2—required</td></tr>
</table>
</td></tr>
<tr><td>SetNewPasswordAllowed</td><td>A Boolean that indicates whether the store password can be changed (true) or not (false).</td></tr>
<tr><td>Password</td><td>An array indicating the source for and details of the credential information Keyfactor Command will use to access the certificates in a specific certificate store (the store password). This is different from credential information Keyfactor Command uses to access a certificate store server as a whole. The former (this setting) is typically used for Java keystores; the latter is typically used for certificates stores on NetScaler and F5 devices and set at the server level, not the certificate store level (see <a>POST Certificate Stores Server on page 1165).
Certificate stores that require credentials support up to three possible credential options:
• Use no store password.
This option is supported for Java keystores that would normally require a password, but can be configured with the no password option (see Value, below).</td></tr>
</table>

Name	Description
	• Store the credential information in the Keyfactor secrets table. A Keyfactor secret is a user-defined password that is encrypted and stored securely in the Keyfactor Command database. • Load the credential information from a PAM provider. See Privileged Access Management (PAM) on page 640 in the *Keyfactor Command Reference Guide* and PAM Providers on page 1439 for more information. The possible values are:

Name	Description

Value	A string—submitted as an object—indicating a password to be stored as a Keyfactor secret.
	
	Tip: To set the no password option on a store, submit the password with a null value. For example:
	`"Password": {`
	`"Value": {null}`
	`}`
	To set the value to a string to be stored in the Keyfactor secrets table, include the password in quotes. For example:
	`"Password": {`
	`"Value": "MyVerySecurePassword"`
	`}`

SecretTypeGuid	A string indicating the Keyfactor Command reference GUID for the type of credentials. This value is automatically set by Keyfactor Command.
InstanceId	The Keyfactor Command reference ID for the secret provider. If you are using a secret provider with an integer ID, this will be used. This value is automatically set by Keyfactor Command.
InstanceGuid	The Keyfactor Command reference GUID for the secret provider. If you are using a secret provider with a GUID ID, this will be used. This value is automatically set by Keyfactor Command.
ProviderTypeParameterValues	An array containing the values for the PAM provider types specified by ProviderTypeParams. The provider type parameter values include:

Name	Description
	Name / **Description** **Name** / **Description** Id — The Keyfactor Command reference ID for the PAM provider type parameter. Value — The value set for the parameter (e.g. the name of the CyberArk folder where the protected object that stores the username or password resides). InstanceId — The Keyfactor Command reference ID for the PAM provider. If you are attaching to something with an integer Id, this will be used. InstanceG-uid — The Keyfactor Command reference GUID for the PAM provider. If you are attaching to something with a GUID ID, this will be used. Provider — An array containing information about the provider. PAM provider details include: **Name** / **Description** Id — An integer indicating the Keyfactor Command reference ID for the PAM provider. Name — A string indicating the internal name for the PAM provider. Area — An integer indicating the area of Keyfactor Command the provider is used for. PAM providers generally have a value of 1, indicating they are used for certificate stores. ProviderType — An array containing details about the provider type for the provider, including:

Name	Description
	Name / **Description** **Name** / **Description** **Name** / **Description** **Name** / **Description** Id — A string indicating the Keyfactor Command reference GUID for the provider type. Name — A string that indicates the name of the provider type. Provider Type Params — An array of parameters that the provider type uses for data input in Keyfactor Command when creating new PAM provider and certificate store records. See below instance of *ProviderTypeParam* for details. ProviderType ParamValues — An array containing the values for the provider types specified by ProviderTypeParams. See the previous level of *ProviderTypeParamValues* for details.

Name	Description
	Name / **Description** **Name** / **Description** **Name** / **Description** SecuredAreaId: An integer indicating the Keyfactor Command reference ID for the certificate store container the PAM provider is associated with, if any. You can create a single PAM provider for each provider type (e.g. CyberArk), however, if you have opted to organize your certificate stores into containers, you will need to create multiple providers to match your container organization structure. The container field in the PAM provider definition is not required, but if one is supplied when creating a PAM provider, the PAM provider can only be used with certificate stores in the matching container. Likewise, a PAM provider defined with no container would be available for selection when setting passwords for any certificate store that also did not specify a container. A PAM provider configured in this way could be used across a variety of certificate stores (e.g. both JKS and F5) as long as they were not in containers. ProviderTypeParam: An array of parameters that the provider type uses for data input in Keyfactor Command when creating new PAM provider and certificate store records. PAM provider type parameters include:

Name	Description
	Name / **Description**
	Name / **Description**
	Name / **Description**
	Name / **Description**
	Id / An integer indicating the Keyfactor Command reference ID for the PAM provider type parameter.
	Name / A string indicating the internal name for the PAM provider type parameter.
	DisplayName / A string indicating the display name for the PAM provider type parameter. For parameters with an InstanceLevel of *false*, this name appears on the PAM provider dialog for the parameter when a user creates a new PAM provider. For parameters with an InstanceLevel of *true*, this name appears on the Server dialog for the parameter when a user creates a new PAM provider.
	DataType / An integer indicating the data type for the parameter. Possible values are: • 1 = String • 2 = Secret
	InstanceLevel / A Boolean that sets whether the parameter is used to define the underlying PAM provider (false) or a field that needs to be set to a value when configuring a certificate store to use the PAM provider (true). For an example, see GET PAM Providers on page 1455.
	Provider- / An array containing details for the

Name	Description
	Name / **Description** ProviderId: An integer indicating the Keyfactor Command reference ID for the PAM provider. IsManaged: A Boolean indicating whether the credentials for the store are managed by a PAM provider (true) or stored in the Keyfactor secrets table (false). This value is automatically set by Keyfactor Command.

Name	Description
	Note: Secret data is stored in the secrets table or a PAM provider and is not returned in responses.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.9.7 GET Certificate Stores ID Inventory

The GET /CertificateStores/{id}/Inventory method is used to return a list of all the certificates found in the selected certificate store based on an inventory done using Keyfactor Command an approved orchestrator. The results include both end entity certificates and chain certificates found in the store. This method allows URL parameters to specify paging and sorting. This method returns HTTP 200 OK on a success with details about the certificates in the store.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateStoreManagement: *Read*

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Table 260: GET Certificate Stores {id} Inventory Input Parameters

Name	In	Description
id	Path	**Required**. A string indicating the GUID of the certificate store within Keyfactor Command.
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *Name*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 261: GET Certificate Stores {id} Inventory Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Name</td><td>A string indicating the alias for the certificate in the certificate store. The format for this varies depending on the certificate store type and whether the Overwrite flag is selected. See PFX Enrollment on page 132 in the Keyfactor Command Reference Guide for more information.</td></tr>
<tr><td>Certificates</td><td>An array of certificates (end entity and chain) found in the certificate store. Certificate details include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of the certificate.</td></tr>
<tr><td>IssuedDN</td><td>A string indicating the distinguished name of the certificate.</td></tr>
<tr><td>SerialNumber</td><td>A string indicating the serial number of the certificate.</td></tr>
<tr><td>NotBefore</td><td>The date, in UTC, on which the certificate was issued by the certificate authority.</td></tr>
<tr><td>NotAfter</td><td>The date, in UTC, on which the certificate expires.</td></tr>
<tr><td>SigningAlgorithm</td><td>A string indicating the algorithm used to sign the certificate.</td></tr>
<tr><td>IssuerDN</td><td>A string indicating the distinguished name of the issuer.</td></tr>
<tr><td>Thumbprint</td><td>A string indicating the thumbprint of the certificate.</td></tr>
<tr><td>CertStoreInventoryItemId</td><td>An integer indicating the Keyfactor Command referenced ID of the certificate in the certificate store.</td></tr>
</table></td></tr>
<tr><td>CertStoreInventoryItemId</td><td>An integer indicating the Keyfactor Command reference ID of the certificate in the certificate store.</td></tr>
<tr><td>Parameters</td><td>An array of entry parameters associated with the certificate in the certificate store. Expected entry parameters will vary depending on the configuration of the certificate store type. See POST Certificate Store Types on page 1247 for more information about entry parameters.</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.9.8 GET Certificate Stores Server

The GET /CertificateStores/Server method is used to retrieve all servers for certificate stores. Only select types of certificate stores have an associated server. These include F5, FTP, NetScaler, and any custom method you've defined to support this. This method returns HTTP 200 OK on a success with details for each server.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateStoreManagement: *Read*

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Note: This method has been deprecated and will be removed from the Keyfactor API in release 12. Certificate store server information is now found in the certificate store (see GET Certificate Stores on page 1100).

Table 262: GET Certificate Stores Server Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Using the Certificate Store Search Feature on page 360 section. The query fields supported for this endpoint are: • *Id* • *Name* • *ServerType*
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *Id*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 263: GET Certificate Stores Server Response Data

Name	Description
Id	The ID of the server.
Username	The username used to connect to the certificate store. **Note:** Secret data is stored in the secrets table or a PAM provider and is not returned in responses.
Password	The password used to connect to the certificate store. **Note:** Secret data is stored in the secrets table or a PAM provider and is not returned in responses.
UseSSL	A Boolean that indicates whether Keyfactor Command will use SSL to communicate with the server (true) or not (false).
ServerType	An integer indicating the type of server. Possible values include (plus any custom values): **Value** / **Description** 0 – F5 Web Server & F5 SSL Profiles 1 – NetScaler 2 – FTP 3 – F5 Web Server REST 4 – F5 SSL Profiles REST 5 – F5 CA Bundles REST
Name	The host name of the server.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.9.9 POST Certificate Stores Server

The POST /CertificateStores/Server method is used to create a new server record for a certificate store in Keyfactor Command. This method returns HTTP 200 OK on a success with details of the newly created server record.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: CertificateStoreManagement: *Modify*

Permissions for certificate stores can be set at either the global or certificate store container level. Creating new certificate store server records requires permissions at the global level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Note: This method has been deprecated and will be removed from the Keyfactor API in a future release. This method is retained until that time for backwards compatibility. Continuing to use this endpoint with the latest Keyfactor Command functionality could cause serious data issues.Certificate store server information is now found in the certificate store (see POST Certificate Stores on page 1108). The Management Portal has additional functionality, such as being able to set different credentials for different stores on the same server, which use the new API endpoint.

Tip: If a certificate store that requires a server is missing a server definition within the store record, the certificate store server created with this method will be used. If no credentials are supplied in the request and no certificate store server exists, an error is returned and the request fails.

Table 264: POST Certificate Stores Server Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>Username</td><td>Body</td><td>Required. The username used to connect to the certificate store. Username parameters include:

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>SecretValue</td><td>A string containing the username.

This value only needs to be supplied if you're storing your username in the Keyfactor Command database.</td></tr>
<tr><td>Provider</td><td>An integer that identifies the PAM provider used to store the username. Use the GET /PamProviders method (see GET PAM Providers on page 1455) to retrieve a list of your defined PAM providers to determine the PAM provider ID to use. See PAM Provider Configuration in Keyfactor Command on page 652 in the Keyfactor Command Reference Guide for more information.

This value only needs to be supplied if you're storing your username using a PAM provider.</td></tr>
<tr><td>Parameters</td><td>The parameters required by your PAM provider, containing the information that identifies the location of the username in the PAM solution. Use the GET /PamProviders method (see GET PAM Providers on page 1455) to retrieve a list of the parameters used by your PAM provider. Only parameters where InstanceLevel is equal to true need to be supplied in the request.

For example, for Delinea (formerly Thycotic), this might be:

<pre>"Username": {
   "Provider": 2,
   "Parameters": {
      "SecretId": 4
   }
},</pre>

For CyberArk, this might be:

<pre>"Username": {
   "Provider": 5,
   "Parameters": {
      "Folder": "Root",
      "Object": "F5Username"
   }
},</pre></td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>Password</td><td>Body</td><td>Required. The password used to connect to the certificate store. Password parameters include:

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>SecretValue</td><td>A string containing the password. This value only needs to be supplied if you're storing your password in the Keyfactor Command database.</td></tr>
<tr><td>Provider</td><td>An integer that identifies the PAM provider used to store the password. Use the GET /PamProviders method (see <a>GET PAM Providers on page 1455) to retrieve a list of your defined PAM providers to determine the PAM provider ID to use.</td></tr>
<tr><td>Parameters</td><td>The parameters required by your PAM provider, containing the information that identifies the location of the password in the PAM solution. Use the GET /PamProviders method (see <a>GET PAM Providers on page 1455) to retrieve a list of the parameters used by your PAM provider. Only parameters where InstanceLevel is equal to true need to be supplied in the request.
For example, for Delinea, this might be:

<pre>"Password": {
   "Provider": 2,
      "Parameters": {
      "SecretId": 5
   }
},</pre>
For CyberArk, this might be:

<pre>"Password": {
   "Provider": 5,
   "Parameters": {
      "Folder": "Root",
      "Object": "F5Password"
   }
},</pre></td></tr>
</table></td></tr>
<tr><td>UseSSL</td><td>Body</td><td>A Boolean that indicates whether Keyfactor Command will use SSL to communicate with the server (true) or not (false). The default is false.</td></tr>
<tr><td>ServerType</td><td>Body</td><td>An integer indicating the type of server. Possible values include (plus any custom values):</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>0</td><td>F5 Web Server & F5 SSL Profiles</td></tr>
<tr><td>1</td><td>NetScaler</td></tr>
<tr><td>2</td><td>FTP</td></tr>
<tr><td>3</td><td>F5 Web Server REST</td></tr>
<tr><td>4</td><td>F5 SSL Profiles REST</td></tr>
<tr><td>5</td><td>F5 CA Bundles REST</td></tr>
</table>
Use the GET /CertificateStoreTypes method (see GET Certificate Store Types on page 1242) to locate the server types for your custom certificate store types. The ServerRegistration value returned by that method maps to the ServerType.
The default is <code>0</code>.
</td></tr>
<tr><td>Name</td><td>Body</td><td>Required. The host name of the server.</td></tr>
<tr><td>Container</td><td>Body</td><td>An integer that identifies the certificate store container into which the certificate store should be placed for organizational and management purposes. This value must be specified if you are using PAM to store your username and/or password and your PAM provider has been configured to be linked to a specific certificate store container.</td></tr>
</table>

Table 265: POST Certificate Stores Server Response Data

Name	Description
Id	The ID of the server.
UseSSL	A Boolean that indicates whether Keyfactor Command will use SSL to communicate with the server (true) or not (false).
ServerType	An integer indicating the type of server. Possible values include (plus any custom values): **Value** / **Description** 0 / F5 Web Server & F5 SSL Profiles 1 / NetScaler 2 / FTP 3 / F5 Web Server REST 4 / F5 SSL Profiles REST 5 / F5 CA Bundles REST
Name	The host name of the server.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.9.10 PUT Certificate Stores Server

The PUT /CertificateStores/Server method is used to update the server record for a certificate store in Keyfactor Command. This method returns HTTP 200 OK on a success with details of the server record.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateStoreManagement: *Modify*

Permissions for certificate stores can be set at either the global or certificate store container level. Updating certificate store server records requires permissions at the global level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Note: This method has been deprecated and will be removed from the Keyfactor API in a future release. This method is retained until that time for backwards compatibility. Continuing to use this endpoint with the latest Keyfactor Command functionality could cause serious data issues. The Management Portal has additional functionality, such as being able to set different credentials for different stores on the same server, which use the new PUT Certificate Stores on page 1128 API endpoint. Using this deprecated API endpoint could potentially, for instance, overwrite all cert stores on the server.

Warning: Any previously populated fields that are not submitted with their full existing data using this method will be cleared of their existing data. When using this method, you should first do a GET to retrieve all the values for the record you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing.

Table 266: PUT Certificate Stores Server Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>Id</td><td>Body</td><td>The ID of the server.</td></tr>
<tr><td>Username</td><td>Body</td><td>Required. The username used to connect to the certificate store. Username parameters
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>SecretValue</td><td>A string containing the username.
This value only needs to be supplied if you're storing your username in the Keyfactor Command database.</td></tr>
<tr><td>Provider</td><td>An integer that identifies the PAM provider used to store the username. Use the GET /PamProviders method (see GET PAM Providers on page 1455) to retrieve a list of your defined PAM providers to determine the PAM provider ID to use. See PAM Provider Configuration in Keyfactor Command on page 652 in the Keyfactor Command Reference Guide for more information.
This value only needs to be supplied if you're storing your username using a PAM provider.</td></tr>
<tr><td>Parameters</td><td>The parameters required by your PAM provider, containing the information that identifies the location of the username in the PAM solution. Use the GET /PamProviders method (see GET PAM Providers on page 1455) to retrieve a list of the parameters used by your PAM provider. Only parameters where InstanceLevel is equal to true need to be supplied in the request.
For example, for Delinea (formerly Thycotic), this might be:
<pre>"Username": {
   "Provider": 2,
   "Parameters": {
      "SecretId": 4
   }
},</pre>For CyberArk, this might be:
<pre>"Username": {
   "Provider": 5,
   "Parameters": {
      "Folder": "Root",
      "Object": "F5Username"
   }
},</pre></td></tr>
</table></td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td></td></tr>
<tr><td>Password</td><td>Body</td><td>Required. The password used to connect to the certificate store. Password parameters include:<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>SecretValue</td><td>A string containing the password. This value only needs to be supplied if you're storing your password in the Keyfactor Command database.</td></tr>
<tr><td>Provider</td><td>An integer that identifies the PAM provider used to store the password. Use the GET /PamProviders method (see GET PAM Providers on page 1455) to retrieve a list of your defined PAM providers to determine the PAM provider ID to use.</td></tr>
<tr><td>Parameters</td><td>The parameters required by your PAM provider, containing the information that identifies the location of the password in the PAM solution. Use the GET /PamProviders method (see GET PAM Providers on page 1455) to retrieve a list of the parameters used by your PAM provider. Only parameters where InstanceLevel is equal to true need to be supplied in the request.
For example, for Delinea, this might be:<pre>"Password": {
   "Provider": 2,
      "Parameters": {
      "SecretId": 5
   }
},</pre>For CyberArk, this might be:<pre>"Password": {
   "Provider": 5,
   "Parameters": {
      "Folder": "Root",
      "Object": "F5Password"
   }
},</pre></td></tr>
</table></td></tr>
<tr><td>UseSSL</td><td>Body</td><td>A Boolean that indicates whether Keyfactor Command will use SSL to communicate with the server (true) or not (false). The default is false.</td></tr>
<tr><td>Name</td><td>Body</td><td>Required. The host name of the server.</td></tr>
</table>

Name	In	Description
Container	Body	An integer that identifies the certificate store container into which the certificate store should be placed for organizational and management purposes. This value must be specified if you are using PAM to store your username and/or password and your PAM provider has been configured to be linked to a specific certificate store container.

Table 267: PUT Certificate Stores Server Response Data

Name	Description
Id	The ID of the server.
UseSSL	A Boolean that indicates whether Keyfactor Command will use SSL to communicate with the server (true) or not (false).
ServerType	An integer indicating the type of server. Possible values include (plus any custom values): **Value** / **Description** 0 / F5 Web Server & F5 SSL Profiles 1 / NetScaler 2 / FTP 3 / F5 Web Server REST 4 / F5 SSL Profiles REST 5 / F5 CA Bundles REST
Name	The host name of the server.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.9.11 PUT Certificate Stores Password

The PUT /CertificateStores/Password method is used to update a password for a certificate store that supports this functionality. This updates the password stored in Keyfactor Command for the certificate store but does not update the certificate store itself. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: CertificateStoreManagement: *Modify*

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Table 268: PUT Certificate Stores Password Input Parameters

<table>
<tr><th>Name</th><th>Type</th><th>Description</th></tr>
<tr><td>CertStoreID</td><td>Body</td><td>Required. A string indicating the GUID of the certificate store. Use the GET CertificateStores method (see GET Certificate Stores on page 1100) to retrieve a list of all your certificate stores to determine the GUID of the store.</td></tr>
<tr><td>NewPassword</td><td>Body</td><td>Required. A array that sets the password used by Keyfactor Command to access the certificate store. It does not impact the certificate store itself, just Keyfactor Command's definition of it. Password settings include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>SecretValue</td><td>A string containing the password. This value only needs to be supplied if you're storing your password in the Keyfactor Command database.</td></tr>
<tr><td>Provider</td><td>An integer that identifies the PAM provider used to store the password. Use the GET /PamProviders method (see GET PAM Providers on page 1455) to retrieve a list of your defined PAM providers to determine the PAM provider ID to use.
This value only needs to be supplied if you're storing your password using a PAM provider.</td></tr>
<tr><td>Parameters</td><td>The parameters required by your PAM provider, containing the information that identifies the location of the password in the PAM solution. Use the GET /PamProviders method (see GET PAM Providers on page 1455) to retrieve a list of the parameters used by your PAM provider. Only parameters where InstanceLevel is equal to true need to be supplied in the request.
For example, for Delinea (formerly Thycotic), this might be:
<pre>"NewPassword": {
 "Provider": 2,
 "Parameters": {
  "SecretId": 5
 }
},</pre>For CyberArk, this might be:
<pre>"NewPassword": {
 "Provider": 5,
 "Parameters": {
  "Folder": "Root",
  "Object": "F5Password"</pre></td></tr>
</table>
</td></tr>
</table>

Name	Type	Description

		Name / **Description**
		}
		},
		
		For a password stored in the Keyfactor Command database, this might be:
		
		`"NewPassword": {`
		`"SecretValue": "P@ssw0rd"`
		`}`

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.9.12 PUT Certificate Stores Discovery Job

The PUT /CertificateStores/DiscoveryJob method is used to schedule a discovery job for certificate stores. The certificate store discovery feature is used to scan machines and devices for existing certificates and certificate stores, which can then be configured for management in Keyfactor Command. Certificate store discovery is supported for:

- PEM and Java certificate stores discovered by the Keyfactor Java Agent. Only stores to which the service account running the Keyfactor Java Agent has at least read permissions will be returned on a discover job.
- F5 bundle and SSL certificates discovered by the Keyfactor Windows Orchestrator on F5 devices using the F5 REST API (v14 and up).
- F5 bundle and SSL certificates discovered by the Keyfactor Universal Orchestrator with a custom extension to support F5. For more information about the Keyfactor Universal Orchestrator and custom extensions, see Universal Orchestrator on page 2358 in the Installing Orchestrators on page 2355.
- Any custom certificate store types configured to support this function.

This endpoint returns 204 with no content upon success. The method schedules the discovery job through the orchestrator. The results of the discovery job are determined separately (see POST Certificate Stores Approve on page 1190).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateStoreManagement: *Modify*

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Table 269: PUT Certificate Stores Discovery Job Input Parameters

Name	In	Description
ClientMachine	Body	**Required**. A string indicating the name in Keyfactor Command of the client machine that will do the discovery. This is not necessarily the actual DNS name of the server; the orchestrator may have been installed using an alternative as a reference name.
AgentId	Body	**Required**. A string indicating the Keyfactor Command reference GUID of the orchestrator for this store.
Type	Body	An integer indicating the ID of the certificate store type, as defined in Keyfactor Command, for this certificate store. (0-Javakeystore,2-PEMFile, 3-F5SSLProfiles,4-IISRoots, 5-NetScaler, 6-IISPersonal, 7-F5WebServer, 8-IISRevoked, 9-F5WebServerREST, 10-F5SSLProfilesREST, 11-F5CABundlesREST, 100-AmazonWebServices, 101-FileTransferProtocol) The default is 0 for a JKS discovery.
JobExecutionTimestamp	Body	The date and time at which the discovery job should run. If no date is provided, the job will be scheduled to run immediately. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).
Dirs	Body	**Required**. A string containing the directory or directories to search during the discovery job. Multiple directories should be separated by commas. **Java** For Java discovery, enter at a minimum either "/" for a Linux server or "c:\" for a Windows server. **PEM** For PEM discovery, enter at a minimum either "/" for a Linux server or "c:\" for a Windows server. **F5** For F5 discovery, enter "/".
IgnoredDirs	Body	A string containing the directories that should not be included in the search. Multiple directories should be separated by commas.
Extensions	Body	A string containing the file extensions for which to search. For example, search for files with the extension "jks" in order to exclude files with other extensions such as "txt". The dot should not be included when specifying extensions.

Name	In	Description
NamePatterns	Body	A string against which to compare the file names of certificate store files and return only those that contain the specified string (e.g. "myjks").
SymLinks	Body	A Boolean that sets whether the job should follow symbolic links on Linux and UNIX operating systems and report both the actual location of a found certificate store file in addition to the symbolic link pointing to the file. This option is ignored on Windows.
Compatibility	Body	A Boolean that sets whether the job will run using the compatibility mode introduced in Java version 1.8 to locate both JKS and PKCS12 type files (true) or not (false). This option applies only to Java keystore discover jobs.

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>ServerUsername</td><td>Body</td><td>Required*. The username used to connect to the certificate store server.

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>SecretValue</td><td>A string containing the username.
This value only needs to be supplied if you're storing your username in the Keyfactor Command database.</td></tr>
<tr><td>Provider</td><td>An integer that identifies the PAM provider used to store the username. Use the GET /PamProviders method (see GET PAM Providers on page 1455) to retrieve a list of your defined PAM providers to determine the PAM provider ID to use. See PAM Provider Configuration in Keyfactor Command on page 652 in the Keyfactor Command Reference Guide for more information.
This value only needs to be supplied if you're storing your username using a PAM provider.</td></tr>
<tr><td>Parameters</td><td>The parameters required by your PAM provider, containing the information that identifies the location of the username in the PAM solution. Use the GET /PamProviders method (see GET PAM Providers on page 1455) to retrieve a list of the parameters used by your PAM provider. Only parameters where InstanceLevel is equal to true need to be supplied in the request.
For example, for Delinea (formerly Thycotic), this might be:
<pre>"ServerUsername": {
 "Provider": 2,
 "Parameters": {
  "SecretId": 4
 }
},</pre>For CyberArk, this might be:
<pre>"ServerUsername": {
 "Provider": 5,
 "Parameters": {
  "Folder": "Root",
  "Object": "F5Username"
 }
},</pre></td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>

Note: Secret data is stored in the secrets table or a PAM provider and is not returned in responses.

This field is **required** only for select certificate store types that require authentication at the server level. These include F5, FTP, NetScaler, and any custom method you've defined to support this.
</td></tr>
<tr><td>ServerPassword</td><td>Body</td><td>

Required*. The password used to connect to the certificate store server. Password parameters include:

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>SecretValue</td><td>A string containing the password. This value only needs to be supplied if you're storing your password in the Keyfactor Command database.</td></tr>
<tr><td>Provider</td><td>An integer that identifies the PAM provider used to store the password. Use the GET /PamProviders method (see GET PAM Providers on page 1455) to retrieve a list of your defined PAM providers to determine the PAM provider ID to use.</td></tr>
<tr><td>Parameters</td><td>The parameters required by your PAM provider, containing the information that identifies the location of the password in the PAM solution. Use the GET /PamProviders method (see GET PAM Providers on page 1455) to retrieve a list of the parameters used by your PAM provider. Only parameters where InstanceLevel is equal to true need to be supplied in the request.
For example, for Delinea, this might be:
<pre>"Password": {
 "Provider": 2,
 "Parameters": {
  "SecretId": 5
 }
},</pre>For CyberArk, this might be:
<pre>"Password": {
 "Provider": 5,
 "Parameters": {
  "Folder": "Root",</pre></td></tr>
</table>

</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td><pre> "Object": "F5Password"
 }
},</pre></td></tr>
</table>
Note: Secret data is stored in the secrets table or a PAM provider and is not returned in responses.
This field is required only for select certificate store types that require authentication at the server level. These include F5, FTP, NetScaler, and any custom method you've defined to support this.
</td></tr>
<tr><td>ServerUseSsl</td><td>Body</td><td>A Boolean that indicates whether Keyfactor Command will use SSL to communicate with the certificate store server (true) or not (false). The default is false.</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.9.13 PUT Certificate Stores Assign Container

The PUT /CertificateStores/AssignContainer method is used to assign one or more certificate stores to a container. This method returns HTTP 200 OK on a success with the certificate stores that were just assigned to a container.

If you are creating a new container and assigning stores to it in one action, you should include the following fields:

- NewContainerName
- NewContainerType
- KeystoreIds

If you are assigning stores to an already existing container, you should include the following fields:

- CertStoreContainerId
- KeystoreIds

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateStoreManagement: *Modify*

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Table 270: PUT Certificate Stores Assign Container Input Parameters

Name	In	Description
CertStoreContainerId	Body	**Required***. An integer that identifies the container into which you want to place the certificate store or stores. One of the following is **required**: • *CertStoreContainerId* • *NewContainerName* and *NewContainerType*
KeystoreIds	Body	**Required**. An array of certificate store GUIDs for the stores you want to place into the container.
NewContainerName	Body	**Required***. A string that sets the name of the container if you would like to create a new container while assigning store(s) to it. One of the following is **required**: • *CertStoreContainerId* • *NewContainerName* and *NewContainerType*
NewContainerType	Body	**Required***. An integer for the container type if you would like to create a new container while assigning store(s) to it. Container types match certificate store types. Use the *GET /CertificateStoreTypes* method with a query (e.g. storetype -eq 7) or *GET /CertificateStoreTypes/{id}* method to determine what a particular certificate store type ID maps to. For example, type 2 maps to *PEM File* and type 10 maps to *F5 SSL Profiles REST*. One of the following is **required**: • *CertStoreContainerId* • *NewContainerName* and *NewContainerType*

Table 271: PUT Certificate Stores Assign Container Response Data

Name	Description
Id	A string indicating the GUID of the certificate store within Keyfactor Command. This ID is automatically set by Keyfactor Command.
ContainerId	An integer indicating the ID of the certificate store's associated certificate store container, if applicable (see GET Certificate Store Containers on page 1212).
ClientMachine	The string value of the client machine. The value for this will vary depending on the certificate store type. For example, for a Java keystore or an F5 device, it is the hostname of the machine on which the store is located, but for an Amazon Web Services store, it is the FQDN of the Keyfactor Command Windows Orchestrator. See Adding or Modifying a Certificate Store on page 363 in the *Keyfactor Command Reference Guide* for more information.
Storepath	A string indicating the path to the certificate store on the target. The format for this path will vary depending on the certificate store type. For example, for a Java keystore, this will be a file path (e.g. /opt/myapp/store.jks), but for an F5 device, this will be a partition name on the device (e.g. Common). See Adding or Modifying a Certificate Store on page 363 in the *Keyfactor Command Reference Guide* for more information. The maximum number of characters supported in this field is 722.
CertStoreInventoryJobId	A string indicating the GUID that identifies the inventory job for the certificate store in the Keyfactor Command database. This will be null if an inventory schedule is not set for the certificate store.
CertStoreType	An integer indicating the ID of the certificate store type, as defined in Keyfactor Command, for this certificate store. (0-Javakeystore,2-PEMFile, 3-F5SSLProfiles,4-IISRoots, 5-NetScaler, 6-IISPersonal, 7-F5WebServer, 8-IISRevoked, 9-F5WebServerREST, 10-F5SSLProfilesREST, 11-F5CABundlesREST, 100-AmazonWebServices, 101-FileTransferProtocol)
Approved	A Boolean that indicates whether a certificate store is approved (true) or not (false). If a certificate store is approved, it can be used and updated. A certificate store that has been discovered using the discover feature but not yet marked as approved will be false here.
CreateIfMissing	A Boolean that indicates whether a new certificate store should be created with the information provided (true) or not (false). This option is only valid for Java keystores and any custom certificate store types you have defined to support this functionality.
Properties	Some types of certificate stores have additional properties that are stored in this parameter. The data is stored in a series of, typically, key value pairs that define the property name and value (see GET Certificate Store Types on page 1242 for more information). As of Keyfactor Command v10, this parameter is used to store certificate store server usernames, server passwords, and the UseSSL flag. Built-in certificate stores that typically require configuration of certificate store server parameters include NetScaler and F5 stores. The legacy methods for managing certificate store server credentials have been deprecated but are retained for backwards compatiblity. For more information, see POST Certificate Stores Server

Name	Description

	on page 1165.
	When reading this field, the values are returned as simple key value pairs, with the values being individual values. When writing, the values are specified as objects, though they are typically single values.
	For example, on a GET request for a *PEM* store configured with a separate private key, the contents of this field might be:
	`"{ \"privateKeyPath\":\"/opt/app/mystore.key\", \"separatePrivateKey\":\"true\" }"`
	However, the syntax used when updating the properties sets the value as a key value pair using *value* as the key. For example, on a POST or PUT request for a *PEM* store configured with a separate private key, the contents of this field might be:
	`"{ \"privateKeyPath\":{\"value\":\"/opt/app/mystore.key\"}, \"separatePrivateKey\":{\"value\":\"true\"} }"`
	An example server properties parameter POST for an FTP or NetScaler store would contain:
	`"{ \"ServerUsername\":{\"value\":{\"SecretValue\":\"User_Name\"}}, \"ServerPassword\":{\"value\":{\"SecretValue\":\"Password\"}}, \"ServerUseSsl\":{\"value\":\"true\"} }"`
	An example server properties parameter POST for an FTP or NetScaler store with the username and password stored as PAM secrets would contain (where the Provider value—1 in this example—is the Id value from GET PAM Providers on page 1455):
	`"{ \"ServerUsername\":{\"value\":{\"Provider\":\"1\",\"Parameters\": {\"SecretId\":\"User_Name\"}}}, \"ServerPassword\":{\"value\":{\"Provider\":\"1\",\"Parameters\": {\"SecretId\":\"Password\"}}}, \"ServerUseSsl\":{\"value\":\"true\"} }"`
	Note: There are three standard properties that are used for any built-in certificate store types that require server credentials (e.g. F5):

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>

ServerUsername
ServerPassword
ServerUseSsl

These replace the separate certificate store server records that existed in previous versions of Keyfactor Command. For legacy support, if credentials are not provided through store properties during creation or editing of a certificate store, Keyfactor Command will attempt to find a certificate store server record and copy the credentials from it into the store properties for future use.

Tip: Built-in stores that make use of this field include:

AWS stores use this field to store secured versions of the access key and secret.
F5 REST stores (all types) use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl) and primary node information (PrimaryNode, PrimaryNodeCheckRetryWaitSecs, PrimaryNodeCheckRetryMax) and F5 version (F5Version).
F5 SOAP stores (all types) use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl).
FTP stores use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl).
IIS stores (all types) use this field to store the UseSSL flag and the port for SMB communications.
Java keystores use this field to store type (ProviderType).
NetScaler stores use this field to store secured versions of the server authentication information (ServerUsername, ServerPassword, ServerUseSsl).
PEM stores use this field to store the path to the private key file, if defined, and the Boolean value indicating whether a separate private key path is defined.

</td></tr>
<tr><td>AgentId</td><td>A string indicating the Keyfactor Command GUID of the orchestrator for this store.</td></tr>
<tr><td>AgentAssigned</td><td>A Boolean that indicates whether there is an orchestrator assigned to this certificate store (true) or not (false).</td></tr>
<tr><td>ContainerName</td><td>A string indicating the name of the certificate store's associated container, if applicable.</td></tr>
<tr><td>InventorySchedule</td><td>The inventory schedule for this certificate store. The following schedule types are supported:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
</table>
</td></tr>
</table>

Name	Description

	<table><tr><th>Name</th><th>Description</th></tr><tr><td>Immediate</td><td>A Boolean that indicates a job scheduled to run immediately (true) or not (false).
	
	Tip: In some instances, jobs initially scheduled as *Immediate* will appear on a GET as *null*.</td></tr><tr><td>Interval</td><td>A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.
	
	<table><tr><th>Name</th><th>Description</th></tr><tr><td>Minutes</td><td>An integer indicating the number of minutes between each interval.</td></tr></table>
	For example, every hour:
	
	<pre>"Interval": {
	  "Minutes": 60
	}</pre></td></tr><tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:
	
	<table><tr><th>Name</th><th>Description</th></tr><tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr></table>
	For example, daily at 11:30 pm:
	
	<pre>"Daily": {
	  "Time": "2022-02-25T23:30:00Z"
	}</pre></td></tr></table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>ExactlyOnce</td><td>A dictionary that indicates a job scheduled to run at the time specified with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, exactly once at 11:45 am:
<pre>"ExactlyOnce": {
   "Time": "2022-02-27T11:45:00Z"
}</pre>
Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as ExactlyOnce.</td></tr>
</table>
Note: Although the Swagger Example Value may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint.
</td></tr>
<tr><td>ReenrollmentStatus</td><td>An array that indicates whether the certificate store can use the re-enrollment function with accompanying data about the re-enrollment job. The following reenrollment fields are supported:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Data</td><td>A Boolean that indicates whether the certificate store can use the re-enrollment function (true) or not (false).</td></tr>
<tr><td>AgentId</td><td>A string indicating the Keyfactor Command GUID of the orchestrator that can re-enroll the certificate store.</td></tr>
<tr><td>Message</td><td>A string indicating the reason the certificate store cannot re-enroll, if applicable.</td></tr>
<tr><td>JobProperties</td><td>An array of key/value pairs for the unique parameters defined</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>for the certificate store type. The key is the name of the specific parameter from the certificate store type definition as returned in the JobProperties on the store type using the GET CertificateStoreTypes method and the value is the value that should be set for that parameter on a certificate in the certificate store. For example, for NetScaler, the key name that is optionally used to associate a certificate with a virtual server is NetscalerVserver and is returned by GET CertificateStoreTypes like so:
<code>"JobProperties": ["NetscalerVserver"]</code>
It can be seen in the Keyfactor Command Management Portal when editing the certificate store type in the field for Management Job Custom Fields.
The setting is referenced using the following format:
<code>"JobProperties": [
{"NetscalerVserver":"MyVirtualServerName"}]</code>
Note: The only built-in certificate store type that makes use of job properties that can be set on a certificate-by-certificate basis in the store is NetScaler. You may have custom certificate store types that make use of this functionality.
This field is optional.</td></tr>
<tr><td>CustomAliasAllowed</td><td>An integer indicating the option for a custom alias for this certificate store.
0—forbidden
1—optional
2—required</td></tr>
</table>
</td></tr>
<tr><td>SetNewPasswordAllowed</td><td>A Boolean that indicates whether the store password can be changed (true) or not (false).</td></tr>
<tr><td>Password</td><td>Note: Secret data is stored in the secrets table or a PAM provider and is not returned in responses.</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.9.14 POST Certificate Stores Approve

The POST /CertificateStores/Approve method is used to approve one or more certificate stores currently in the pending state—having been discovered using the certificate store discover option (see PUT Certificate Stores Discovery Job on page 1177). If more than one certificate store is included in the array, all stores must be of the same store type (e.g. Java keystore). This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateStoreManagement: *Modify*

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Table 272: POST Certificate Stores Approve Input Parameters

Name	In	Description
Id	Body	**Required**. The GUID of the pending certificate store. Use the *GET /CertificateStores* method (see GET Certificate Stores on page 1100) with a query of "Approved -eq false" to retrieve a list of all your unapproved certificate stores to determine the GUID of the store.
ContainerId	Body	An integer that identifies the container in which the certificate store should be placed on approval. Use the *GET /CertificateStores/Containers* method (see GET Certificate Store Containers on page 1212) to retrieve a list of your defined certificate store containers to determine the container ID to use.
CertStoreType	Body	**Required**. An integer indicating the ID of the certificate store type, as defined in Keyfactor Command, for this certificate store. (0-Javakeystore,2-PEMFile, 3-F5SSLProfiles,4-IISRoots, 5-NetScaler, 6-IISPersonal, 7-F5WebServer, 8-IISRevoked, 9-F5WebServerREST, 10-F5SSLProfilesREST, 11-F5CABundlesREST, 100-AmazonWebServices, 101-FileTransferProtocol)

Properties	Body	**Required***. Some types of certificate stores have additional properties that are stored in this parameter. The data is stored in a series of, typically, key value pairs that define the property name and value (see GET Certificate Store Types on page 1242 for more information).
		When reading this field, the values are returned as simple key value pairs, with the values being individual values. When writing, the values are specified as objects, though they are typically single values.
		For example, on a GET request for a *PEM* store configured with a separate private key, the contents of this field might be:
		`"{ \"privateKeyPath\":\"/opt/app/mystore.key\", \"separatePrivateKey\":\"true\" }"`
		However, the syntax used when updating the properties sets the value as a key value pair using *value* as the key. For example, on a POST or PUT request for a *PEM* store configured with a separate private key, the contents of this field might be:
		`"{ \"privateKeyPath\":{\"value\":\"/opt/app/mystore.key\"}, \"separatePrivateKey\":{\"value\":\"true\"} }"`
		This field is **required** for certificate store types that store additional properties in this parameter.

Password	Body	**Required**. An array indicating the source for and details of the credential information Keyfactor Command will use to access the certificates in a specific certificate store (the store password). This is different from credential information Keyfactor Command uses to access a certificate store server as a whole. The former (this setting) is typically used for Java keystores; the latter is typically used for certificates stores on NetScaler and F5 devices and set at the server level, not the certificate store level (see POST Certificate Stores Server on page 1165). Certificate stores that require credentials support up to three possible credential options:

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>

Use no store password.
This option is supported for Java keystores that would normally require a password, but can be configured with the no password option (see Value, below).
Store the credential information in the Keyfactor secrets table.
A Keyfactor secret is a user-defined password that is encrypted and stored securely in the Keyfactor Command database.
Load the credential information from a PAM provider.
See Privileged Access Management (PAM) on page 640 in the Keyfactor Command Reference Guide and PAM Providers on page 1439 for more information.

The possible values are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Value</td><td>A string—submitted as an object—indicating a password to be stored as a Keyfactor secret.

Tip: To set the no password option on a store, submit the password with a null value. For example:
<pre>"Password": {
   "Value": {null}
}</pre>To set the value to a string to be stored in the Keyfactor secrets table, include the password in quotes. For example:
<pre>"Password": {
   "Value": "MyVerySecurePassword"
}</pre></td></tr>
<tr><td>SecretTypeGuid</td><td>A string indicating the Keyfactor Command reference GUID for the type of credentials. This value is automatically set by Keyfactor Command.</td></tr>
<tr><td>InstanceId</td><td>The Keyfactor Command reference ID for the secret provider. If you are using a secret provider with an integer ID, this will be used. This value is automatically set by Keyfactor Command.</td></tr>
<tr><td>InstanceGuid</td><td>The Keyfactor Command reference GUID for the secret provider. If you are using a secret provider with a GUID ID, this will be used. This value is automatically set by Keyfactor Command.</td></tr>
<tr><td>Provider-TypePara-meterValues</td><td>An array containing the values for the provider types specified by ProviderTypeParams. PAM provider type parameter values include:</td></tr>
</table>
</td></tr>
</table>

Name	In	Description
		Name / **Description** Id — The Keyfactor Command reference ID for the PAM provider type parameter. Value — The value set for the parameter (e.g. the name of the CyberArk folder where the protected object that stores the username or password resides). InstanceId — The Keyfactor Command reference ID for the PAM provider. If you are attaching to something with an integer Id, this will be used. InstanceGuid — The Keyfactor Command reference GUID for the PAM provider. If you are attaching to something with a GUID ID, this will be used. Provider — An array containing information about the provider. PAM provider details include: **Name** / **Description** Id — An integer indicating the Keyfactor Command reference ID for the PAM provider. Name — A string indicating the internal name for the PAM provider. Area — An integer indicating the area of Keyfactor Command the provider is used for. PAM providers generally have a value of 1, indicating they are used for certificate stores. ProviderType — An array containing details about the provider type for the provider, including:

Name	In	Description
		Name / **Description** **Name** / **Description** **Name** / **Description** **Name** / **Description** Id — A string indicating the Keyfactor Command reference GUID for the provider type. Name — A string that indicates the name of the provider type. ProviderTypeParams — An array of parameters that the provider type uses for data input in Keyfactor Command when creating new PAM provider and certificate store records. See below instance of *ProviderTypeParam* for details. ProviderType — An array containing the values

Name	In	Description
		Name / **Description** **Name** / **Description** **Name** / **Description** Para-mValues — for the provider types specified by ProviderTypeParams. See the previous level of *Provider-TypeParamValues* for details. SecuredAre-aId — An integer indicating the Keyfactor Command reference ID for the certificate store container the PAM provider is associated with, if any. You can create a single PAM provider for each provider type (e.g. CyberArk), however, if you have opted to organize your certificate stores into containers, you will need to create multiple providers to match your container organization structure. The container field in the PAM provider definition is not required, but if one is supplied when creating a PAM provider, the PAM provider can only be used with certificate stores in the matching container. Likewise, a PAM provider defined with no container would be available for selection when setting passwords for any certificate store that also did not specify a container. A PAM provider configured in this way could be used across a variety of certificate stores (e.g. both JKS and

Name	In	Description
		Name / **Description** **Name** / **Description** **Name** / **Description** F5) as long as they were not in containers. Provider-Type Param: An array of parameters that the provider type uses for data input in Keyfactor Command when creating new PAM provider and certificate store records. PAM provider type parameters include: **Name** / **Description** Id: An integer indicating the Keyfactor Command reference ID for the PAM provider type parameter. Name: A string indicating the internal name for the PAM provider type parameter. DisplayName: A string indicating the display name for the PAM provider type parameter. For parameters with an InstanceLevel of *false*, this name appears on the PAM provider dialog for the parameter when a user creates a new PAM provider. For parameters with an InstanceLevel of *true*, this name appears on the Server dialog for the parameter when a user creates a new PAM provider. DataType: An integer indicating the data type for the parameter. Possible values are:

Name	In	Description
		Name / **Description** **Name** / **Description** **Name** / **Description** • 1 = String • 2 = Secret InstanceLevel: A Boolean that sets whether the parameter is used to define the underlying PAM provider (false) or a field that needs to be set to a value when configuring a certificate store to use the PAM provider (true). For an example, see GET PAM Providers on page 1455. ProviderType: An array containing details for the provider type. **Name** / **Description** Id: A string indicating the Keyfactor Command reference GUID for the PAM provider type parameter. Name: A string

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Descrip-tion</th></tr>
<tr><td></td><td>indicating the internal name for the PAM provider type para-meter.</td></tr>
<tr><td>Provider-TypeParams</td><td>Unused field</td></tr>
</table>
</td></tr>
</table>
</td></tr>
<tr><td>Provider</td><td>An integer indicating the Keyfactor Command reference ID for the PAM provider.</td></tr>
<tr><td>IsManaged</td><td>A Boolean indicating whether the credentials for the store are managed by a PAM provider (true) or stored in the Keyfactor secrets table (false). This value is automatically set by Keyfactor Command.</td></tr>
</table>
This field is required for Java keystores.
</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon () at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.9.15 POST Certificate Stores Schedule

The POST /CertificateStores/Schedule method is used to create and assign a schedule to one or more certificate stores in Keyfactor Command. The POST request must contain an array of certificate store GUIDs and the properties that make up the schedule to attach to the store(s). This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: CertificateStoreManagement: *Schedule*

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Table 273: POST Certificate Stores Schedule Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>StoreIds</td><td>Body</td><td>Required. An array of strings providing the certificate store GUIDs to schedule.</td></tr>
<tr><td>Schedule</td><td>Body</td><td>Required. The inventory schedule for the certificate store(s). Supported schedules are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
<tr><td>Immediate</td><td>A Boolean that indicates a job scheduled to run immediately (true) or not (false).

Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as null.</td></tr>
<tr><td>Interval</td><td>A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Minutes</td><td>An integer indicating the number of minutes between each interval.</td></tr>
</table>
For example, every hour:
<pre>"Interval": {
   "Minutes": 60
}</pre></td></tr>
<tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, daily at 11:30 pm:</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td><pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre></td></tr>
<tr><td>ExactlyOnce</td><td>A dictionary that indicates a job scheduled to run at the time specified with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, exactly once at 11:45 am:
<pre>"ExactlyOnce": {
   "Time": "2022-02-27T11:45:00Z"
}</pre>
Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as ExactlyOnce.</td></tr>
</table>
Note: Although the Swagger Example Value may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint.
</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.9.16 POST Certificate Stores Reenrollment

The POST /CertificateStores/Reenrollment method is used to schedule an existing certificate store for reenrollment. The reenrollment method is available for:

- PEM certificate stores managed by the Native Agent.
- PEM and Java certificate stores managed by Java and Android Agents.

- Any custom certificate store types created to support this functionality.

This endpoint returns 204 with no content upon success. Use the GET /OrchestratorJobs/JobHistory method to check on the progress of the job after submission (see GET Orchestrator Jobs Job History on page 1416).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateEnrollment: *EnrollCSR*
CertificateStoreManagement: *Modify*

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

In addition, the either the user scheduling the reenrollment job or the user configured to provide authentication to the CA (see Authorization Methods Tab on page 322 in the *Keyfactor Command Reference Guide*) must have enrollment permissions configured on the CA and template.

Table 274: POST Certificates Stores Reenrollment Input Parameters

Name	In	Description
KeystoreId	Body	**Required**. The GUID of the certificate store to schedule for reenrollment. Use the *GET /CertificateStores* method (see GET Certificate Stores on page 1100) to retrieve a list of your certificate stores to determine the GUID of the store.
SubjectName	Body	**Required**. A string containing the reenrollment subject name using X.500 format. For example: `"SubjectName": "CN=websrvr14.keyexample.com,OU=IT,O=\"Key Example, Inc.\",L=Independence,ST=OH,C=US"`
AgentGuid	Body	**Required**. The GUID of the orchestrator that is registered with the certificate store. Use the *GET /CertificateStores* method (see GET Certificate Stores on page 1100) to retrieve a list of your certificate stores to determine the GUID of the orchestrator associated with the store.
Alias	Body	**Required**. The alias of the certificate in the certificate store.

JobProperties	Body	An array of key/value pairs for the unique parameters defined for the certificate store type. The *key* is the name of the specific parameter from the certificate store type definition as returned in the JobProperties on the store type using the *GET CertificateStoreTypes* method and the *value* is the value that should be set for that parameter on a certificate in the certificate store. For example, for NetScaler, the key name that is optionally used to associate a certificate with a virtual server is *NetscalerVserver* and is returned by *GET CertificateStoreTypes* like so:
		`"JobProperties": [ "NetscalerVserver" ]`
		It can be seen in the Keyfactor Command Management Portal when editing the certificate store type in the field for *Management Job Custom Fields*.
		The setting is referenced using the following format:
		`"JobProperties": [ {"NetscalerVserver":"MyVirtualServerName"} ]`
		Note: The only built-in certificate store type that makes use of job properties that can be set on a certificate-by-certificate basis in the store is NetScaler, which does not support reenrollment. You may have custom certificate store types that make use of this functionality.

CertificateAuthority	Body	A string indicating the certificate authority to which to direct the enrollment request. If this parameter is not provided, the value set in the *Certificate Authority For Submitted CSRs* application setting will be used (see Application Settings: Agents Tab on page 565 in the *Keyfactor Command Reference Guide*).
CertificateTemplate	Body	A string indicating the certificate template to use for the enrollment request. If this parameter is not provided, the value set in the *Template For Submitted CSRs*

Name	In	Description
		application setting will be used (see Application Settings: Agents Tab on page 565 in the *Keyfactor Command Reference Guide*).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.9.17 POST Certificate Stores Certificates Add

The POST /CertificateStores/Certificates/Add method is used to add a certificate to one or more certificate stores. The POST request must contain a certificate ID and an array of certificate store GUIDs that identify the stores to which the certificate should be added. This method returns HTTP 200 OK on a success with an array of GUIDs for the add jobs. Use the GET /OrchestratorJobs/JobHistory method to check on the progress of the job after submission (see GET Orchestrator Jobs Job History on page 1416).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
Certificates: *Read*
CertificateStoreManagement: *Schedule*

Permissions for certificates and certificate stores can be set at either the global or certificate collection and certificate store container level. See Certificate Permissions on page 588 and Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs collection and container permissions.

Table 275: POST Certificate Stores Certificates Add Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>CertificateId</td><td>Body</td><td>Required. An integer containing the Keyfactor Command reference ID of the certificate to be added to the certificate store(s).</td></tr>
<tr><td>CertificateStores</td><td>Body</td><td>Required. An array of certificate store GUIDs to identify the certificate stores to which the certificate should be added and provide appropriate reference information for the certificate in the store. Parameters include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>CertificateStoreIds</td><td>Required. A string containing the GUID for the certificate store to which the certificate should be added.</td></tr>
<tr><td>Alias</td><td>Required*. A string providing an alias to be used for the certificate upon entry into the certificate store. The function of the alias varies depending on the certificate store type. For example, for an F5 device, it serves as the file name used to store the file in the device file system, minus the extension (e.g. use alias MyFile for a file named MyFile.pfx) while for a Java keystore, it is stored in the keystore associated with the certificate. Some certificate store types don't require an alias and some do. See Add Certificate on page 65 in the Keyfactor Command Reference Guide for more information. This field may be required depending on the store type selected.</td></tr>
<tr><td>JobFields</td><td>An array of key/value pairs that sets extra values for the job fields that will be associated with the add job. This option is typically used with custom Any Agent implementations.</td></tr>
<tr><td>Overwrite</td><td>A Boolean that sets whether a certificate in the store with the Alias provided should be overwritten with the certificate being added (true) or not (false). The default is false.
Use the GET /Certificates/Locations/{id} method (see GET Certificates Locations ID on page 940) to retrieve a list of the locations an existing certificate is in to determine the alias used for the certificate in the certificate store.</td></tr>
<tr><td>EntryPassword</td><td>The password to set on the entry within the certificate store, if applicable. Only select certificate stores support entry passwords (e.g. Java keystores). Entry password</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>values include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>SecretValue</td><td>A string containing the password. This value only needs to be supplied if you're storing your password in the Keyfactor Command database.</td></tr>
<tr><td>Provider</td><td>An integer that identifies the PAM provider used to store the password. Use the GET /PamProviders method (see <a>GET PAM Providers on page 1455) to retrieve a list of your defined PAM providers to determine the PAM provider ID to use.</td></tr>
<tr><td>Parameters</td><td>The parameters required by your PAM provider, containing the information that identifies the location of the password in the PAM solution. Use the GET /PamProviders method (see <a>GET PAM Providers on page 1455) to retrieve a list of the parameters used by your PAM provider. Only parameters where InstanceLevel is equal to true need to be supplied in the request.
For example, for Delinea (formerly Thycotic), this might be:
<pre>"EntryPassword": {
  "Provider": 2,
  "Parameters": {
    "SecretId": 5
  }</pre></td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>},
For CyberArk, this might be:
<pre>"EntryPassword": {
  "Provider": 5,
  "Parameters": {
    "Folder":
"Root",
    "Object":
"F5Password"
  }
},</pre></td></tr>
</table>
</td></tr>
<tr><td>PfxPassword</td><td>A string that sets the password to use when saving a certificate with its private key in the certificate store. This is only relevant if there's a private key being added along with the certificate.</td></tr>
<tr><td>IncludePrivateKey</td><td>A Boolean that sets whether to include the private key of the certificate in the certificate store if private keys are optional for the given certificate store (true) or not (false). The default is false.</td></tr>
</table>
For example, to add to one IIS personal store and one NetScaler store without overwriting an existing certificate:
<pre>"CertificateStores": [
   {
      "Alias": "MyCertificate.pfx",
      "CertificateStoreId": "fde12aa7-6643-43db-88e8-5c91c5ce78b3",
      "IncludePrivateKey": true
   },
   {
      "Alias": "C2107973A928859C21330E566B299CD4A0705AE8",
      "CertificateStoreId": "322e12ea-43b2-4aab-80ae-c4ad4569b4e7",
      "IncludePrivateKey": true
   }
]</pre>
</td></tr>
<tr><td>Schedule</td><td>Body</td><td>Required. The inventory schedule for the add job. Possible schedule values include:</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
<tr><td>Immediate</td><td>A Boolean that indicates a job scheduled to run immediately (true) or not (false).

Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as null.</td></tr>
<tr><td>ExactlyOnce</td><td>A dictionary that indicates a job scheduled to run at the time specified with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, exactly once at 11:45 am:
<pre>"ExactlyOnce": {
   "Time": "2022-02-27T11:45:00Z"
}</pre>
Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as ExactlyOnce.</td></tr>
</table>
Note: Although the Swagger Example Value may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint.
</td></tr>
<tr><td>CollectionId</td><td>Body</td><td>An integer specifying an optional certificate collection identifier to validate that the user executing the request has sufficient permissions to do so. If a certificate collection ID is not supplied, the user must have global permissions to complete the action. Supplying a certificate collection ID allows for a check of the user's certificate collection-level permissions to determine whether the user has sufficient permissions at a collection level to complete the action. See Certificate Permissions on page 588 in the Keyfactor Command Reference Guide for more information.</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.9.18 POST Certificate Stores Certificates Remove

The POST /CertificateStores/Certificates/Remove method is used to remove a certificate from one or more certificate stores. The POST request must contain an array of certificate store GUIDs and the certificate properties that identify the certificate to remove. This method returns HTTP 200 OK on a success with an array of GUIDs for the removal jobs. Use the GET /OrchestratorJobs/JobHistory method to check on the progress of the job after submission (see GET Orchestrator Jobs Job History on page 1416).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
Certificates: *Read*
CertificateStoreManagement: *Schedule*

Permissions for certificates and certificate stores can be set at either the global or certificate collection and certificate store container level. See Certificate Permissions on page 588 and Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs collection and container permissions.

Table 276: POST Certificate Stores Certificates Remove Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>CertificateStores</td><td>Body</td><td>Required. An array of certificate store GUIDs and related information to identify the certificate to remove from the certificate store(s). Certificate store detail includes:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Alias</td><td>Required. A string containing the unique identifier for the certificate in the certificate store. Each type of certificate store has a different format for this alias. Use the GET /Certificates/{id} method (see <a>GET Certificates ID on page 945) to retrieve the certificate store IDs in which the certificate is stored (CertStoreId) and the aliases under which the certificate is stored in these stores. This information is also available in the certificate details in the Management Portal.</td></tr>
<tr><td>CertificateStoreIds</td><td>Required. A string containing the GUID for the certificate store from which the certificate should be removed.</td></tr>
<tr><td>JobFields</td><td>An array of key/value pairs that sets extra values for the job fields that will be associated with the removal job. This option is typically used with custom Any Agent implementations.</td></tr>
</table>
For example, to remove from one IIS personal store and one NetScaler store:
<pre>
"CertificateStores": [
   {
      "Alias": "MyCertificate.pfx",
      "CertificateStoreId": "fde12aa7-6643-43db-88e8-5c91c5ce78b3"
   },
   {
      "Alias": "C2107973A928859C21330E566B299CD4A0705AE8",
      "CertificateStoreId": "322e12ea-43b2-4aab-80ae-c4ad4569b4e7"
   }
]
</pre></td></tr>
<tr><td>Schedule</td><td>Body</td><td>Required. The inventory schedule for the removal job. Supported schedules are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
</table></td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Immediate</td><td>A Boolean that indicates a job scheduled to run immediately (true) or not (false).

Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as null.</td></tr>
<tr><td>ExactlyOnce</td><td>A dictionary that indicates a job scheduled to run at the time specified with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, exactly once at 11:45 am:
<pre>"ExactlyOnce": {
   "Time": "2022-02-27T11:45:00Z"
}</pre>
Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as ExactlyOnce.</td></tr>
</table>
Note: Although the Swagger Example Value may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint.
</td></tr>
<tr><td>CollectionId</td><td>Body</td><td>An integer specifying an optional certificate collection identifier to validate that the user executing the request has sufficient permissions to do so. If a certificate collection ID is not supplied, the user must have global permissions to complete the action. Supplying a certificate collection ID allows for a check of the user's certificate collection-level permissions to determine whether the user has sufficient permissions at a collection level to complete the action. See Certificate Permissions on page 588 in the Keyfactor Command Reference Guide for more information.</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.10 Certificate Store Containers

The CertificateStoreContainers component of the Keyfactor API provides a set of methods to support management of certificate store containers.

Table 277: Certificate Store Containers Endpoints

Endpoint	Method	Description	Link
/	GET	Returns a list of certificate store containers.	GET Certificate Store Containers below
/	POST	Adds a certificate store container.	POST Certificate Store Containers on page 1215
/{id}	DELETE	Deletes a certificate store container.	DELETE Certificate Store Containers ID on page 1223
/{id}	GET	Returns details for the specified certificate store container.	GET Certificate Store Containers ID on page 1224
/{id}	PUT	Edits a certificate store container.	PUT Certificate Store Containers on page 1219

3.2.10.1 GET Certificate Store Containers

The GET /CertificateStoreContainers method is used to retrieve all certificate store containers. This method returns HTTP 200 OK on a success with container details.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateStoreManagement: *Read*

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Table 278: GET Certificate Store Containers Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Using the Containers Search Feature on page 394. The query fields supported for this endpoint are: • *CertStoreType* (0-Javakeystore,2-PEMFile, 3-F5SSLProfiles,4-IISRoots, 5-NetScaler, 6-IISPersonal, 7-F5WebServer, 8-IISRevoked, 9-F5WebServerREST, 10-F5SSLProfilesREST, 11-F5CABundlesREST, 100-AmazonWebServices, 101-FileTransferProtocol) • *HasSchedule* (True, False) • *Id* • *Name*(Short Name)
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *Name*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 279: GET Certificate Stores Containers Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the ID of the container.</td></tr>
<tr><td>Name</td><td>A string indicating the name of the container.</td></tr>
<tr><td>Over-writeSchedules</td><td>A Boolean indicating whether the schedule set on the container will overwrite schedules set individually on the certificate stores (true) or not (false).</td></tr>
<tr><td>Schedule</td><td>A string containing the inventory schedule set for the container. Supported schedules are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
<tr><td>Interval</td><td>A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Minutes</td><td>An integer indicating the number of minutes between each interval.</td></tr>
</table>
For example, every hour:
<pre>"Interval": {
   "Minutes": 60
}</pre></td></tr>
<tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, daily at 11:30 pm:
<pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre></td></tr>
</table></td></tr>
</table>

Name	Description
	Note: Although the Swagger *Example Value* may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint.
CertStoreType	An integer indicating the ID of the certificate store type, as defined in Keyfactor Command, for this certificate store. (0-Javakeystore,2-PEMFile, 3-F5SSLProfiles,4-IISRoots, 5-NetScaler, 6-IISPersonal, 7-F5WebServer, 8-IISRevoked, 9-F5WebServerREST, 10-F5SSLProfilesREST, 11-F5CABundlesREST, 100-AmazonWebServices, 101-FileTransferProtocol)
StoreCount	An integer indicating the number of stores of the type referenced by CertStoreType in the container.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.10.2 POST Certificate Store Containers

The POST /CertificateStoreContainers method is used to add a new certificate store container. This method returns HTTP 200 OK on a success with container details.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateStoreManagement: *Modify*

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Table 280: POST Certificate Stores Containers Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>Name</td><td>Body</td><td>Required. A string indicating the name of the container.</td></tr>
<tr><td>Schedule</td><td>Body</td><td>A string containing the inventory schedule set for the container. Supported schedules are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
<tr><td>Interval</td><td>A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Minutes</td><td>An integer indicating the number of minutes between each interval.</td></tr>
</table>
For example, every hour:
<pre>"Interval": {
   "Minutes": 60
}</pre></td></tr>
<tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, daily at 11:30 pm:
<pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre></td></tr>
</table>
Note: Although the Swagger Example Value may show examples of various other schedules, only the schedules shown here—that are available in the Management</td></tr>
</table>

Name	In	Description
		Portal for this functionality—are valid for this endpoint.
CertStoreTyp-e	Body	An integer indicating the ID of the certificate store type, as defined in Keyfactor Command, for this certificate store. (0-Javakeystore,2-PEMFile, 3-F5SSLProfiles,4-IISRoots, 5-NetScaler, 6-IISPersonal, 7-F5WebServer, 8-IISRevoked, 9-F5WebServerREST, 10-F5SSLProfilesREST, 11-F5CABundlesREST, 100-AmazonWebServices, 101-FileTransferProtocol) The default is 0 for a JKS keystore.

Table 281: POST Certificate Stores Containers Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the ID of the container.</td></tr>
<tr><td>Name</td><td>A string indicating the name of the container.</td></tr>
<tr><td>Schedule</td><td>A string containing the inventory schedule set for the container. Supported schedules are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
<tr><td>Interval</td><td>A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Minutes</td><td>An integer indicating the number of minutes between each interval.</td></tr>
</table>
For example, every hour:
<pre>"Interval": {
   "Minutes": 60
}</pre></td></tr>
<tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, daily at 11:30 pm:
<pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre></td></tr>
</table>
Note: Although the Swagger Example Value may show examples of various other schedules,</td></tr>
</table>

Name	Description
	only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint.
CertStoreType	An integer indicating the ID of the certificate store type, as defined in Keyfactor Command, for this certificate store. (0-Javakeystore,2-PEMFile, 3-F5SSLProfiles,4-IISRoots, 5-NetScaler, 6-IISPersonal, 7-F5WebServer, 8-IISRevoked, 9-F5WebServerREST, 10-F5SSLProfilesREST, 11-F5CABundlesREST, 100-AmazonWebServices, 101-FileTransferProtocol)

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.10.3 PUT Certificate Store Containers

The PUT /CertificateStoreContainers method is used to edit the specified certificate store container. This method returns HTTP 200 OK on a success with container details.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateStoreManagement: *Modify*

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Warning: Any previously populated fields that are not submitted with their full existing data using this method will be cleared of their existing data. When using this method, you should first do a GET to retrieve all the values for the record you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing.

Table 282: PUT Certificate Store Containers Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>Id</td><td>Path</td><td>Required. An integer indicating the ID of the container.</td></tr>
<tr><td>Name</td><td>Body</td><td>Required. A string indicating the name of the container.</td></tr>
<tr><td>Schedule</td><td>Body</td><td>A string containing the inventory schedule set for the container. Supported schedules are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
<tr><td>Interval</td><td>A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Minutes</td><td>An integer indicating the number of minutes between each interval.</td></tr>
</table>
For example, every hour:
<pre>"Interval": {
   "Minutes": 60
}</pre></td></tr>
<tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, daily at 11:30 pm:
<pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre></td></tr>
</table>
</td></tr>
</table>

Name	In	Description
		Note: Although the Swagger *Example Value* may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint.
CertStoreTyp-e	Body	An integer indicating the ID of the certificate store type, as defined in Keyfactor Command, for this certificate store. (0-Javakeystore,2-PEMFile, 3-F5SSLProfiles,4-IISRoots, 5-NetScaler, 6-IISPersonal, 7-F5WebServer, 8-IISRevoked, 9-F5WebServerREST, 10-F5SSLProfilesREST, 11-F5CABundlesREST, 100-AmazonWebServices, 101-FileTransferProtocol) The default is 0 for a JKS keystore.

Table 283: PUT Certificate Store Containers Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the ID of the container.</td></tr>
<tr><td>Name</td><td>A string indicating the name of the container.</td></tr>

Note: Although the Swagger Example Value may show examples of various other schedules,</td></tr>
</table>

Name	Description
	only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint.
CertStoreType	An integer indicating the ID of the certificate store type, as defined in Keyfactor Command, for this certificate store. (0-Javakeystore,2-PEMFile, 3-F5SSLProfiles,4-IISRoots, 5-NetScaler, 6-IISPersonal, 7-F5WebServer, 8-IISRevoked, 9-F5WebServerREST, 10-F5SSLProfilesREST, 11-F5CABundlesREST, 100-AmazonWebServices, 101-FileTransferProtocol)

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.10.4 DELETE Certificate Store Containers ID

The DELETE /CertificateStoreContainers/{id} method is used to delete the certificate store container with the specified ID. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateStoreManagement: *Modify*

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Table 284: DELETE Certificate Store Containers {id} Input Parameters

Name	In	Description
id	Path	**Required**. A string containing the ID of the certificate store container to delete. Use the *GET /CertificateStoreContainers* method (see GET Certificate Store Containers on page 1212) to retrieve a list of all the certificate store containers to determine the certificate store container ID.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.10.5 GET Certificate Store Containers ID

The GET /CertificateStoreContainers/{id} method is used to retrieve the certificate store container with the specified ID. This method returns HTTP 200 OK on a success with container details.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateStoreManagement: *Read*

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Table 285: GET Certificate Store Containers {id} Input Parameters

Name	In	Description
id	Path	**Required**. A string containing the ID of the certificate store container. Use the *GET /CertificateStoreContainers* method (see GET Certificate Store Containers on page 1212) to retrieve a list of all the certificate store containers to determine the certificate store container ID.

Table 286: GET Certificate Stores Containers {id} Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the ID of the container.</td></tr>
<tr><td>Name</td><td>A string indicating the name of the container.</td></tr>
<tr><td>Schedule</td><td>A string containing the inventory schedule set for the container. Supported schedules are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
<tr><td>Interval</td><td>A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Minutes</td><td>An integer indicating the number of minutes between each interval.</td></tr>
</table>
For example, every hour:
<pre>"Interval": {
   "Minutes": 60
}</pre></td></tr>
<tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, daily at 11:30 pm:
<pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre></td></tr>
</table>
Note: Although the Swagger Example Value may show examples of various other schedules,</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint.</td></tr>
<tr><td>CertStoreType</td><td>An integer indicating the ID of the certificate store type, as defined in Keyfactor Command, for this certificate store. (0-Javakeystore,2-PEMFile, 3-F5SSLProfiles,4-IISRoots, 5-NetScaler, 6-IISPersonal, 7-F5WebServer, 8-IISRevoked, 9-F5WebServerREST, 10-F5SSLProfilesREST, 11-F5CABundlesREST, 100-AmazonWebServices, 101-FileTransferProtocol)</td></tr>
<tr><td>CertificateStores</td><td>An array of certificate store data for the certificate stores within this container. Certificate store details include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>A string indicating the GUID of the certificate store within Keyfactor Command.</td></tr>
<tr><td>DisplayName</td><td>A string indicating the display name of the certificate store.</td></tr>
<tr><td>ContainerId</td><td>An integer indicating the ID of the certificate store's associated certificate store container.</td></tr>
<tr><td>ClientMachine</td><td>The string value of the client machine. The value for this will vary depending on the certificate store type. For example, for a Java keystore or an F5 device, it is the hostname of the machine on which the store is located, but for an Amazon Web Services store, it is the FQDN of the Keyfactor Command Windows Orchestrator. See Adding or Modifying a Certificate Store on page 363 in the Keyfactor Command Reference Guide for more information.</td></tr>
<tr><td>Storepath</td><td>A string indicating the path to the certificate store on the target. The format for this path will vary depending on the certificate store type. For example, for a Java keystore, this will be a file path (e.g. /opt/myapp/store.jks), but for an F5 device, this will be a partition name on the device (e.g. Common). See Adding or Modifying a Certificate Store on page 363 in the Keyfactor Command Reference Guide for more information.</td></tr>
<tr><td>CertStoreInventoryJobId</td><td>A string indicating the GUID that identifies the inventory job for the certificate store in the Keyfactor Command database. This will be null if an inventory schedule is not set for the certificate store.</td></tr>
</table></td></tr>
</table>

Name	Description

	<table><tr><th>Name</th><th>Description</th></tr><tr><td>CertStoreType</td><td>An integer indicating the ID of the certificate store type, as defined in Keyfactor Command, for this certificate store. (0-Javakeystore,2-PEMFile, 3-F5SSLProfiles,4-IISRoots, 5-NetScaler, 6-IISPersonal, 7-F5WebServer, 8-IISRevoked, 9-F5WebServerREST, 10-F5SSLProfilesREST, 11-F5CABundlesREST, 100-AmazonWebServices, 101-FileTransferProtocol)</td></tr><tr><td>Approved</td><td>A Boolean that indicates whether a certificate store is approved (true) or not (false). If a certificate store is approved, it can be used and updated. A certificate store that has been discovered using the discover feature but not yet marked as approved will be false here.</td></tr><tr><td>CreateIfMissing</td><td>A Boolean that indicates whether a new certificate store should be created with the information provided (true) or not (false). This option is only valid for Java keystores and any custom certificate store types you have defined to support this functionality.</td></tr><tr><td>Properties</td><td>Some types of certificate stores have additional properties that are stored in this parameter. The data is stored in a series of, typically, key value pairs that define the property name and value (see GET Certificate Store Types on page 1242 for more information).
	When reading this field, the values are returned as simple key value pairs, with the values being individual values. When writing, the values are specified as objects, though they are typically single values.
	For example, on a GET request for a PEM store configured with a separate private key, the contents of this field might be:
	<pre>"{
	  \"privateKeyPath\":\"/opt/app/mystore.key\",
	  \"separatePrivateKey\":\"true\"
	}"</pre>
	However, the syntax used when updating the properties sets the value as a key value pair using value as the key. For example, on a POST or PUT request for a PEM store configured with a separate private key, the contents of this field might be:</td></tr></table>

Name	Description

	<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td><pre>"{
	  \"privateKeyPath\":{\"value\":\"/-
	opt/app/mystore.key\"},
	  \"separatePrivateKey\":{\"value\":\"true\"}
	}"</pre>
	Tip: Built-in stores that make use of this field include: - AWS stores use this field to store secured versions of the access key and secret. - F5 REST stores (all types) use this field to store the primary node information (PrimaryNode, PrimaryNodeCheckRetryWaitSecs, PrimaryNodeCheckRetryMax) and F5 version (F5Version). - IIS stores (all types) use this field to store the port for SMB communications. - PEM stores use this field to store the path to the private key file, if defined, and the Boolean value indicating whether a separate private key path is defined. </td></tr><tr><td>AgentId</td><td>A string indicating the Keyfactor Command GUID of the orchestrator for this store.</td></tr><tr><td>AgentAssigned</td><td>A Boolean that indicates whether there is an orchestrator assigned to this certificate store (true) or not (false).</td></tr><tr><td>ContainerName</td><td>A string indicating the name of the certificate store's associated container.</td></tr><tr><td>InventorySchedule</td><td>The inventory schedule for this certificate store.</td></tr><tr><td>ReenrollmentStatus</td><td>An array that indicates whether the certificate store can use the re-enrollment function with accompanying data about the re-enrollment job.</td></tr><tr><td>SetNewPasswordAllowed</td><td>A Boolean that indicates whether the store password can be changed (true) or not (false).</td></tr><tr><td>Password</td><td>An array indicating the source for and details of the credential</td></tr></table>

Name	Description
	Name / **Description** information Keyfactor Command will use to access the certificates in a specific certificate store (the store password). **Note:** Secret data is stored in the secrets table or a PAM provider and is not returned in responses.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.11 Certificate Store Types

CertificateStoreTypes define constraints and properties of different kinds of certificates stores. Keyfactor Command contains default certificate store types and also allows users to define certificate store types for custom certificate stores.

Table 287: Certificate Store Type Endpoints

Endpoint	Method	Description	Link
/{id}	DELETE	Deletes a certificate store type using StoreType number.	DELETE Certificate Store Types ID on the next page
/{id}	GET	Returns certificate store type details for the specified certificate store type using StoreType number.	GET Certificate Store Types ID on the next page
/Name/{name}	GET	Returns certificate store type details for the specified certificate store type using ShortName.	GET CertificateStoreTypes Name Name on page 1235
/	DELETE	Delete multiple certificate store types using StoreType number.	DELETE Certificate Store Types on page 1241
/	GET	Returns all certificate store types with paging and options to the specified detail level.	GET Certificate Store Types on page 1242
/	POST	Creates a new certificate store type.	POST Certificate Store Types on page 1247
/	PUT	Updates a certificate store type using StoreType number.	PUT Certificate Store Types on page 1259

3.2.11.1 DELETE Certificate Store Types ID

The DELETE /CertificateStoreTypes/{id} method is used to delete an existing certificate store type with the specified ID. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: CertificateStoreManagement: *Modify*

Table 288: DELETE Certificate Store Types {id} Input Parameters

Name	In	Description
id	Path	**Required**. The ID of the certificate store type to delete. Use the *GET /CertificateStoreTypes* method (see GET Certificate Store Types on page 1242) to retrieve a list of all the certificate store types to determine the certificate store type ID.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.11.2 GET Certificate Store Types ID

The GET /CertificateStoreTypes/{id} method is used to return the certificate store type with the specified ID. This method returns HTTP 200 OK on a success with details for the certificate store type specified.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: CertificateStoreManagement: *Read*

Table 289: GET Certificate Store Types {id} Input Parameters

Name	In	Description
id	Path	**Required**. The ID of the certificate store type. Use the *GET /CertificateStoreTypes* method (see GET Certificate Store Types on page 1242) to retrieve a list of all the certificate store types to determine the certificate store type ID.

Table 290: GET Certificate Store Types {id} Response Data

Name	Description
Name	A string containing the full name of the certificate store type.
ShortName	A string containing the short name assigned to the certificate store type.
Capability	A string containing a reference name for the certificate store type (e.g. NS for a NetScaler store).
StoreType	A unique integer for the certificate store type. The ID is automatically assigned by Keyfactor Command.
ImportType	An integer that indicates the import type for the certificate store type. The ID is automatically assigned by Keyfactor Command and generally matches the *StoreType* for custom certificate store types.
LocalStore	A Boolean that indicates whether the store is local to the orchestrator machine (true) as, for example, JKS and PEM stores managed by the Keyfactor Java Agent or remote (false) as, for example, IIS stores managed by the Keyfactor Universal Orchestrator.
SupportedOperations	An array containing a series of Boolean values that indicate whether the certificate store type is enabled for the following functions: • Add • Create • Discovery • Enrollment • Remove
Properties	An array of unique parameters for the certificate store type. In the Keyfactor Command Management Portal these are known as *Custom Fields*. Property parameters include:

Name	Description
Name	A string containing the short name of the property.
DisplayName	A string containing the full display name of the property.
Type	A string containing the type of the property: • String • Bool • MultipleChoice • Secret

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>DependsOn</td><td>A string containing the name of the parameter on which this parameter depends. This only applies if at least two custom parameters have been created for this certificate store type. This option is used to configure one custom parameter to display only if another custom parameter contains a value.</td></tr>
<tr><td>DefaultValue</td><td>A string containing the default value(s) of the parameter. If Type is Multiple Choice, this field should contain a comma-separated list of multiple choice options for this parameter. If Type is Boolean, this field should contain true or false.</td></tr>
<tr><td>Required</td><td>A Boolean that indicates whether the parameter is required (true) or not (false).</td></tr>
</table>
Note: There are three standard properties that are used for any built-in certificate store types that require server credentials (e.g. F5):

ServerUsername
ServerPassword
ServerUseSsl

These replace the separate certificate store server records that existed in previous versions of Keyfactor Command. For legacy support, if credentials are not provided through store properties during creation or editing of a certificate store, Keyfactor Command will attempt to find a certificate store server record and copy the credentials from it into the store properties for future use.
</td></tr>
<tr><td>PasswordOptions</td><td>Options for the password in the certificate store type. Password options include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>EntrySupported</td><td>A Boolean that indicates whether entry of a password for the certificate in the certificate store is allowed (true) or not (false).</td></tr>
<tr><td>StoreRequired</td><td>A Boolean that indicates whether entry of a password on the certificate store as a whole is required (true) or not (false).</td></tr>
<tr><td>Style</td><td>A string containing the style of password:
Default: Keyfactor Command will randomly generate a password.
Custom: Allow a password to be entered and authen-</td></tr>
</table>
</td></tr>
</table>

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td>ticated when enrolling for a certificate through Keyfactor Command when installing to a store of this type. The Custom option can be selected only if the *Allow Custom Password* in the Application Settings, is equal to *True*. For more details, see Application Settings: Enrollment Tab on page 560 in the*Keyfactor Command Reference Guide*.</td></tr></table>
StorePathValue	An array containing the value(s) for the certificate store path.
PrivateKeyAllowed	A string containing the option for private key requirements for certificates stored in stores with this certificate store type: • *Forbidden*: Private key is not required; generally, applies to trust stores (e.g. Root CA certificates). • *Optional*: Private key is optional; applies to store types that could represent either a Trust Store or End-Entity Store. • *Required*: Private key is required; applies to stores that hold an End-Entity Certificate (server or client authorization).
ServerRequired	A Boolean that indicates whether server access is required for adding certificate stores for this certificate store type (true) or not (false). If set to true, a user will be prompted for a user-name and password to connect to the remote server.
PowerShell	A Boolean that indicates whether jobs for the store type are implemented using PowerShell (true) instead of a .NET class or not (false).
BlueprintAllowed	A Boolean that indicates whether certificate stores of this type will be included when creating or applying blueprints. For more details, see Orchestrator Blueprints on page 475 in the *Keyfactor Command Reference Guide*.
CustomAliasAllowed	A string containing the selected certificate store type alias option: • *Forbidden*: A custom alias is not required and cannot be supplied. • *Optional*: A custom alias is optional. • *Required*: A custom alias is required. The certificate store alias serves as an identifier for the certificate in the store. Depending on the type of store, it may be a file name, a certificate thumbprint, a string reference, or some other information. Some types of stores may not support associating an alias with the certificate (e.g. IIS trusted root).
EntryParameters	An array of unique parameters that are required when performing management jobs on a certificate store of this type. Entry parameter options include:

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td>Name</td><td>A string containing the short name of the entry parameter.</td></tr><tr><td>DisplayName</td><td>A string containing the full display name of the entry parameter.</td></tr><tr><td>Type</td><td>A string containing the type of the entry parameter: - String - Bool - MultipleChoice - Secret </td></tr><tr><td>RequiredWhen</td><td>An array of Boolean values indicating the circumstances under which a value is required to be provided for this entry parameter. These are: - HasPrivateKey: If set to true, a value must be provided for this field when configuring a management job (either add or remove) if the certificate has an associated private key in Keyfactor Command. This would be the case, for example, when doing a PFX enrollment and adding the resulting certificate to a certificate store. - OnAdd: If set to true, a value must be provided for this field when configuring an add certificate job. - OnRemove: If set to true, a value must be provided for this field when configuring a remove certificate job. - OnReenrollment: If set to true, a value must be provided for this field when configuring a reenrollment job. </td></tr><tr><td>DependsOn</td><td>A string containing the name of the parameter on which this parameter depends. This only applies if at least two custom parameters have been created for this certificate store type. This option is used to configure one custom parameter to display only if another custom parameter contains a value.</td></tr><tr><td>DefaultValue</td><td>A string containing the default value for the entry parameter. If Type is Multiple Choice, this field should contain a single value that represents the default selection from the provided list (see Options) for this entry parameter. If Type is Boolean, this field should contain true or false.</td></tr><tr><td>Options</td><td>A string containing a comma-separated list of multiple choice options for this entry parameter.</td></tr></table>

Name	Description
	Tip: What's the difference between properties (custom fields) and entry parameters? • Properties are about the certificate store definition itself and are static. For example, you might use a property to define the primary node name of an F5 instance. This node name is the same no matter what inventory or management jobs you do with the F5 device(s). Values for properties are entered in the certificate store record when creating or editing the certificate store record. • Entry parameters are about the specific certificate within the certificate store. They are used to send additional information related to the certificate to the server or device that hosts the certificate store when running management jobs for that certificate store. Often this is more fluid information that isn't the same for every use of that certificate store. For example, several virtual servers with separate certificates in the same folder may exist on a NetScaler device. When replacing one certificate, updates may need to be made to only the virtual server that is using the certificate. In this case, the authorized user will be prompted to enter the virtual server name based on an entry parameter. Values for entry parameters are entered at the time a management job is initiated (e.g. adding a certificate to a certificate store).
InventoryEndpoint	A string containing the orchestrator endpoint to which inventory updates are sent.
InventoryJobType	A GUID identifying the job type for inventory jobs.
ManagementJobType	A GUID identifying the job type for management jobs.
DiscoveryJobType	A GUID identifying the job type for discovery jobs.
EnrollmentJobType	A GUID identifying the job type for reenrollment jobs.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.11.3 GET CertificateStoreTypes Name Name

The GET /CertificateStoreTypes/Name/{name} method is used to return the certificate store type with the specified short name. This method returns HTTP 200 OK on a success with details for the certificate store type specified.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: CertificateStoreManagement: *Read*

Table 291: GET Certificate Store Types Name {ShortName} Input Parameters

Name	In	Description
name	Path	**Required**. The short name of the certificate store type. Use the *GET /CertificateStoreTypes* method (see GET Certificate Store Types on page 1242) to retrieve a list of all the certificate store types to determine the certificate store type short name.

Table 292: GET Certificate Store Types Name {ShortName} Response Data

Name	Description
Name	A string containing the full name of the certificate store type.
ShortName	A string containing the short name assigned to the certificate store type.
Capability	A string containing a reference name for the certificate store type (e.g. NS for a NetScaler store).
StoreType	A unique integer for the certificate store type. The ID is automatically assigned by Keyfactor Command.
ImportType	An integer that indicates the import type for the certificate store type. The ID is automatically assigned by Keyfactor Command and generally matches the *StoreType* for custom certificate store types.
LocalStore	A Boolean that indicates whether the store is local to the orchestrator machine (true) as, for example, JKS and PEM stores managed by the Keyfactor Java Agent or remote (false) as, for example, IIS stores managed by the Keyfactor Universal Orchestrator.
SupportedOperations	An array containing a series of Boolean values that indicate whether the certificate store type is enabled for the following functions: • Add • Create • Discovery • Enrollment • Remove
Properties	An array of unique parameters for the certificate store type. In the Keyfactor Command Management Portal these are known as *Custom Fields*. Property parameters include:

Name	Description
Name	A string containing the short name of the property.
DisplayName	A string containing the full display name of the property.
Type	A string containing the type of the property: • String • Bool • MultipleChoice • Secret

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>DependsOn</td><td>A string containing the name of the parameter on which this parameter depends. This only applies if at least two custom parameters have been created for this certificate store type. This option is used to configure one custom parameter to display only if another custom parameter contains a value.</td></tr>
<tr><td>DefaultValue</td><td>A string containing the default value(s) of the parameter. If Type is Multiple Choice, this field should contain a comma-separated list of multiple choice options for this parameter. If Type is Boolean, this field should contain true or false.</td></tr>
<tr><td>Required</td><td>A Boolean that indicates whether the parameter is required (true) or not (false).</td></tr>
</table>

Note: There are three standard properties that are used for any built-in certificate store types that require server credentials (e.g. F5):

ServerUsername
ServerPassword
ServerUseSsl

These replace the separate certificate store server records that existed in previous versions of Keyfactor Command. For legacy support, if credentials are not provided through store properties during creation or editing of a certificate store, Keyfactor Command will attempt to find a certificate store server record and copy the credentials from it into the store properties for future use.
</td></tr>
<tr><td>PasswordOptions</td><td>Options for the password in the certificate store type. Password options include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>EntrySupported</td><td>A Boolean that indicates whether entry of a password for the certificate in the certificate store is allowed (true) or not (false).</td></tr>
<tr><td>StoreRequired</td><td>A Boolean that indicates whether entry of a password on the certificate store as a whole is required (true) or not (false).</td></tr>
<tr><td>Style</td><td>A string containing the style of password:

Default: Keyfactor Command will randomly generate a password.
Custom: Allow a password to be entered and authen-

</td></tr>
</table>
</td></tr>
</table>

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td>ticated when enrolling for a certificate through Keyfactor Command when installing to a store of this type. The Custom option can be selected only if the *Allow Custom Password* in the Application Settings, is equal to *True*. For more details, see Application Settings: Enrollment Tab on page 560 in the*Keyfactor Command Reference Guide*.</td></tr></table>
StorePathValue	An array containing the value(s) for the certificate store path.
PrivateKeyAllowed	A string containing the option for private key requirements for certificates stored in stores with this certificate store type: • *Forbidden*: Private key is not required; generally, applies to trust stores (e.g. Root CA certificates). • *Optional*: Private key is optional; applies to store types that could represent either a Trust Store or End-Entity Store. • *Required*: Private key is required; applies to stores that hold an End-Entity Certificate (server or client authorization).
ServerRequired	A Boolean that indicates whether server access is required for adding certificate stores for this certificate store type (true) or not (false). If set to true, a user will be prompted for a user-name and password to connect to the remote server.
PowerShell	A Boolean that indicates whether jobs for the store type are implemented using PowerShell (true) instead of a .NET class or not (false).
BlueprintAllowed	A Boolean that indicates whether certificate stores of this type will be included when creating or applying blueprints. For more details, see Orchestrator Blueprints on page 475 in the *Keyfactor Command Reference Guide*.
CustomAliasAllowed	A string containing the selected certificate store type alias option: • *Forbidden*: A custom alias is not required and cannot be supplied. • *Optional*: A custom alias is optional. • *Required*: A custom alias is required. The certificate store alias serves as an identifier for the certificate in the store. Depending on the type of store, it may be a file name, a certificate thumbprint, a string reference, or some other information. Some types of stores may not support associating an alias with the certificate (e.g. IIS trusted root).
EntryParameters	An array of unique parameters that are required when performing management jobs on a certificate store of this type. Entry parameter options include:

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td>Name</td><td>A string containing the short name of the entry parameter.</td></tr><tr><td>DisplayName</td><td>A string containing the full display name of the entry parameter.</td></tr><tr><td>Type</td><td>A string containing the type of the entry parameter: - String - Bool - MultipleChoice - Secret </td></tr><tr><td>RequiredWhen</td><td>An array of Boolean values indicating the circumstances under which a value is required to be provided for this entry parameter. These are: - HasPrivateKey: If set to true, a value must be provided for this field when configuring a management job (either add or remove) if the certificate has an associated private key in Keyfactor Command. This would be the case, for example, when doing a PFX enrollment and adding the resulting certificate to a certificate store. - OnAdd: If set to true, a value must be provided for this field when configuring an add certificate job. - OnRemove: If set to true, a value must be provided for this field when configuring a remove certificate job. - OnReenrollment: If set to true, a value must be provided for this field when configuring a reenrollment job. </td></tr><tr><td>DependsOn</td><td>A string containing the name of the parameter on which this parameter depends. This only applies if at least two custom parameters have been created for this certificate store type. This option is used to configure one custom parameter to display only if another custom parameter contains a value.</td></tr><tr><td>DefaultValue</td><td>A string containing the default value for the entry parameter. If Type is Multiple Choice, this field should contain a single value that represents the default selection from the provided list (see Options) for this entry parameter. If Type is Boolean, this field should contain true or false.</td></tr><tr><td>Options</td><td>A string containing a comma-separated list of multiple choice options for this entry parameter.</td></tr></table>

Name	Description
	Tip: What's the difference between properties (custom fields) and entry parameters? • Properties are about the certificate store definition itself and are static. For example, you might use a property to define the primary node name of an F5 instance. This node name is the same no matter what inventory or management jobs you do with the F5 device(s). Values for properties are entered in the certificate store record when creating or editing the certificate store record. • Entry parameters are about the specific certificate within the certificate store. They are used to send additional information related to the certificate to the server or device that hosts the certificate store when running management jobs for that certificate store. Often this is more fluid information that isn't the same for every use of that certificate store. For example, several virtual servers with separate certificates in the same folder may exist on a NetScaler device. When replacing one certificate, updates may need to be made to only the virtual server that is using the certificate. In this case, the authorized user will be prompted to enter the virtual server name based on an entry parameter. Values for entry parameters are entered at the time a management job is initiated (e.g. adding a certificate to a certificate store).
InventoryEndpoint	A string containing the orchestrator endpoint to which inventory updates are sent.
InventoryJobType	A GUID identifying the job type for inventory jobs.
ManagementJobType	A GUID identifying the job type for management jobs.
DiscoveryJobType	A GUID identifying the job type for discovery jobs.
EnrollmentJobType	A GUID identifying the job type for reenrollment jobs.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.11.4 DELETE Certificate Store Types

The DELETE /CertificateStoreTypes method is used to delete multiple certificate store types in one request. The certificate store type IDs should be supplied in the request body as a JSON array of integers. IDs of any certificate store types that could not be deleted are returned in the response body. Delete operations will continue until the entire array of IDs has been processed. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: CertificateStoreManagement: *Modify*

Table 293: DELETE Certificate Store Types Input Parameters

Name	In	Description
ids	Body	**Required**. An array of Keyfactor Command certificate store type IDs for certificate store types that should be deleted in the form (without parameter name): `[106,108,109]` Use the *GET /CertificateStoreTypes* method (see GET Certificate Store Types below) to retrieve a list of all the certificate store types to determine the certificate store type IDs.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.11.5 GET Certificate Store Types

The GET /CertificateStoreTypes method is used to retrieve a list of all certificate store types. This method returns HTTP 200 OK on a success with details of the certificate store types.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: CertificateStoreManagement: *Read*

Table 294: GET Certificate Store Types Input Parameters

Name	In	Description
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.

Table 295: GET Certificate Store Types Response Data

Name	Description
Name	A string containing the full name of the certificate store type.
ShortName	A string containing the short name assigned to the certificate store type.
Capability	A string containing a reference name for the certificate store type (e.g. NS for a NetScaler store).
StoreType	A unique integer for the certificate store type. The ID is automatically assigned by Keyfactor Command.
ImportType	An integer that indicates the import type for the certificate store type. The ID is automatically assigned by Keyfactor Command and generally matches the *StoreType* for custom certificate store types.
LocalStore	A Boolean that indicates whether the store is local to the orchestrator machine (true) as, for example, JKS and PEM stores managed by the Keyfactor Java Agent or remote (false) as, for example, IIS stores managed by the Keyfactor Universal Orchestrator.
SupportedOperations	An array containing a series of Boolean values that indicate whether the certificate store type is enabled for the following functions: • Add • Create • Discovery • Enrollment • Remove
Properties	An array of unique parameters for the certificate store type. In the Keyfactor Command Management Portal these are known as *Custom Fields*. Property parameters include:

Name	Description
Name	A string containing the short name of the property.
DisplayName	A string containing the full display name of the property.
Type	A string containing the type of the property: • String • Bool • MultipleChoice • Secret

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>DependsOn</td><td>A string containing the name of the parameter on which this parameter depends. This only applies if at least two custom parameters have been created for this certificate store type. This option is used to configure one custom parameter to display only if another custom parameter contains a value.</td></tr>
<tr><td>DefaultValue</td><td>A string containing the default value(s) of the parameter. If Type is Multiple Choice, this field should contain a comma-separated list of multiple choice options for this parameter. If Type is Boolean, this field should contain true or false.</td></tr>
<tr><td>Required</td><td>A Boolean that indicates whether the parameter is required (true) or not (false).</td></tr>
</table>

Note: There are three standard properties that are used for any built-in certificate store types that require server credentials (e.g. F5):

ServerUsername
ServerPassword
ServerUseSsl

These replace the separate certificate store server records that existed in previous versions of Keyfactor Command. For legacy support, if credentials are not provided through store properties during creation or editing of a certificate store, Keyfactor Command will attempt to find a certificate store server record and copy the credentials from it into the store properties for future use.
</td></tr>
<tr><td>PasswordOptions</td><td>Options for the password in the certificate store type. Password options include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>EntrySupported</td><td>A Boolean that indicates whether entry of a password for the certificate in the certificate store is allowed (true) or not (false).</td></tr>
<tr><td>StoreRequired</td><td>A Boolean that indicates whether entry of a password on the certificate store as a whole is required (true) or not (false).</td></tr>
<tr><td>Style</td><td>A string containing the style of password:

Default: Keyfactor Command will randomly generate a password.
Custom: Allow a password to be entered and authen-

</td></tr>
</table>
</td></tr>
</table>

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td>ticated when enrolling for a certificate through Keyfactor Command when installing to a store of this type. The Custom option can be selected only if the *Allow Custom Password* in the Application Settings, is equal to *True*. For more details, see Application Settings: Enrollment Tab on page 560 in the*Keyfactor Command Reference Guide*.</td></tr></table>
StorePathValue	An array containing the value(s) for the certificate store path.
PrivateKeyAllowed	A string containing the option for private key requirements for certificates stored in stores with this certificate store type: • *Forbidden*: Private key is not required; generally, applies to trust stores (e.g. Root CA certificates). • *Optional*: Private key is optional; applies to store types that could represent either a Trust Store or End-Entity Store. • *Required*: Private key is required; applies to stores that hold an End-Entity Certificate (server or client authorization).
ServerRequired	A Boolean that indicates whether server access is required for adding certificate stores for this certificate store type (true) or not (false). If set to true, a user will be prompted for a user-name and password to connect to the remote server.
PowerShell	A Boolean that indicates whether jobs for the store type are implemented using PowerShell (true) instead of a .NET class or not (false).
BlueprintAllowed	A Boolean that indicates whether certificate stores of this type will be included when creating or applying blueprints. For more details, see Orchestrator Blueprints on page 475 in the *Keyfactor Command Reference Guide*.
CustomAliasAllowed	A string containing the selected certificate store type alias option: • *Forbidden*: A custom alias is not required and cannot be supplied. • *Optional*: A custom alias is optional. • *Required*: A custom alias is required. The certificate store alias serves as an identifier for the certificate in the store. Depending on the type of store, it may be a file name, a certificate thumbprint, a string reference, or some other information. Some types of stores may not support associating an alias with the certificate (e.g. IIS trusted root).
EntryParameters	An array of unique parameters that are required when performing management jobs on a certificate store of this type. Entry parameter options include:

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td>Name</td><td>A string containing the short name of the entry parameter.</td></tr><tr><td>DisplayName</td><td>A string containing the full display name of the entry parameter.</td></tr><tr><td>Type</td><td>A string containing the type of the entry parameter: - String - Bool - MultipleChoice - Secret </td></tr><tr><td>RequiredWhen</td><td>An array of Boolean values indicating the circumstances under which a value is required to be provided for this entry parameter. These are: - HasPrivateKey: If set to true, a value must be provided for this field when configuring a management job (either add or remove) if the certificate has an associated private key in Keyfactor Command. This would be the case, for example, when doing a PFX enrollment and adding the resulting certificate to a certificate store. - OnAdd: If set to true, a value must be provided for this field when configuring an add certificate job. - OnRemove: If set to true, a value must be provided for this field when configuring a remove certificate job. - OnReenrollment: If set to true, a value must be provided for this field when configuring a reenrollment job. </td></tr><tr><td>DependsOn</td><td>A string containing the name of the parameter on which this parameter depends. This only applies if at least two custom parameters have been created for this certificate store type. This option is used to configure one custom parameter to display only if another custom parameter contains a value.</td></tr><tr><td>DefaultValue</td><td>A string containing the default value for the entry parameter. If Type is Multiple Choice, this field should contain a single value that represents the default selection from the provided list (see Options) for this entry parameter. If Type is Boolean, this field should contain true or false.</td></tr><tr><td>Options</td><td>A string containing a comma-separated list of multiple choice options for this entry parameter.</td></tr></table>

Name	Description
	Tip: What's the difference between properties (custom fields) and entry parameters? • Properties are about the certificate store definition itself and are static. For example, you might use a property to define the primary node name of an F5 instance. This node name is the same no matter what inventory or management jobs you do with the F5 device(s). Values for properties are entered in the certificate store record when creating or editing the certificate store record. • Entry parameters are about the specific certificate within the certificate store. They are used to send additional information related to the certificate to the server or device that hosts the certificate store when running management jobs for that certificate store. Often this is more fluid information that isn't the same for every use of that certificate store. For example, several virtual servers with separate certificates in the same folder may exist on a NetScaler device. When replacing one certificate, updates may need to be made to only the virtual server that is using the certificate. In this case, the authorized user will be prompted to enter the virtual server name based on an entry parameter. Values for entry parameters are entered at the time a management job is initiated (e.g. adding a certificate to a certificate store).
InventoryEndpoint	A string containing the orchestrator endpoint to which inventory updates are sent.
InventoryJobType	A GUID identifying the job type for inventory jobs.
ManagementJobType	A GUID identifying the job type for management jobs.
DiscoveryJobType	A GUID identifying the job type for discovery jobs.
EnrollmentJobType	A GUID identifying the job type for reenrollment jobs.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.11.6 POST Certificate Store Types

The POST /CertificateStoresTypes method is used to create certificate store types in Keyfactor Command. This method returns HTTP 200 OK on a success with a message body containing a list of certificate store type details.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateStoreManagement: *Modify*

Table 296: POST Certificate Store Types Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>Name</td><td>Body</td><td>Required. A string containing the full name of the certificate store type. A unique value must be supplied.</td></tr>
<tr><td>ShortName</td><td>Body</td><td>Required. A string containing the short name assigned to the certificate store type. A unique value must be supplied with a maximum of 10 characters.</td></tr>
<tr><td>Capability</td><td>Body</td><td>A string containing a reference name for the certificate store type (e.g. NS for a NetScaler store).</td></tr>
<tr><td>LocalStore</td><td>Body</td><td>A Boolean that indicates whether the store is local to the orchestrator machine (true) as, for example, JKS and PEM stores managed by the Keyfactor Java Agent or remote (false) as, for example, IIS stores managed by the Keyfactor Universal Orchestrator. The default is false.</td></tr>
<tr><td>SupportedOperations</td><td>Body</td><td>An array containing a series of Boolean values that indicate whether the certificate store type is enabled for the following functions:
Add
Create
Discovery
Enrollment
Remove
The default for each value is false.</td></tr>
<tr><td>Properties</td><td>Body</td><td>An array of unique parameters for the certificate store type. In the Keyfactor Command Management Portal these are known as Custom Fields. Property parameters include:<table><tr><th>Name</th><th>Description</th></tr><tr><td>Name</td><td>Required. A string containing the short name of the property. If you choose to define a property, this field is required.</td></tr><tr><td>DisplayName</td><td>Required. A string containing the full display name of the property. If you choose to define a property, this field is required.</td></tr><tr><td>Type</td><td>Required. A string containing the type of the property:
String
Bool
MultipleChoice</td></tr></table></td></tr>
</table>

Name	In	Description
		<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td>• Secret If you choose to define a property, this field is **required**.</td></tr><tr><td>DependsOn</td><td>A string containing the name of the parameter on which this parameter depends. This only applies if at least two custom parameters have been created for this certificate store type. This option is used to configure one custom parameter to display only if another custom parameter contains a value.</td></tr><tr><td>DefaultValue</td><td>A string containing the default value(s) of the parameter. If *Type* is *Multiple Choice*, this field should contain a comma-separated list of multiple choice options for this parameter. If *Type* is *Boolean*, this field should contain *true* or *false*.</td></tr><tr><td>Required</td><td>A Boolean that indicates whether the parameter is required (true) or not (false).</td></tr></table> **Note:** There are three standard properties that are used for any built-in certificate store types that require server credentials (e.g. F5): • ServerUsername • ServerPassword • ServerUseSsl These replace the separate certificate store server records that existed in previous versions of Keyfactor Command. For legacy support, if credentials are not provided through store properties during creation or editing of a certificate store, Keyfactor Command will attempt to find a certificate store server record and copy the credentials from it into the store properties for future use. For example, to set a multiple choice property: `"Properties": [ { "Name": "Pets", "DisplayName": "Popular Pets", "Type": "MultipleChoice", "DependsOn": "", "DefaultValue": "Cat,Dog,Fish,Rat,Mouse",`

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>

<pre>
      "Required": false
   }
]
</pre>

This value is unset by default.</td></tr>
<tr><td>PasswordOptions</td><td>Body</td><td>Options for the password in the certificate store type. Password options include:

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>EntrySupported</td><td>A Boolean that indicates whether entry of a password for the certificate in the certificate store is allowed (true) or not (false). The default is false.</td></tr>
<tr><td>StoreRequired</td><td>A Boolean that indicates whether entry of a password on the certificate store as a whole is required (true) or not (false). The default is false.</td></tr>
<tr><td>Style</td><td>A string containing the style of password:
• Default: Keyfactor Command will randomly generate a password.
• Custom: Allow a password to be entered and authenticated when enrolling for a certificate through Keyfactor Command when installing to a store of this type. The Custom option can be selected only if the Allow Custom Password in the Application Settings, is equal to True. For more details, see Application Settings: Enrollment Tab on page 560 in theKeyfactor Command Reference Guide.

The default value is Default.</td></tr>
</table>
</td></tr>
<tr><td>StorePathType</td><td>Body</td><td>A string containing the selected store type:
• Freeform: Users are required to enter a path defining the certificate store location.
• Fixed: A store path does not apply, generally one store per device (e.g. IIS).
• MultipleChoice: Allow a comma separated list of options to be entered that users will be able to select from when defining the certificate store location.</td></tr>
</table>

Name	In	Description
		This value is unset by default.
StorePathValue	Body	An array containing the value(s) for the certificate store path if the *StorePathType* is set to Fixed or Multiple Choice. Multiple choice values should be provided in a bracketed comma-delimited list like so: `"StorePathValue": "[\"Apple\",\"Cherry\",\"Peach\",\"Pear\"]"` This value is unset by default.
PrivateKeyAllowed	Body	A string containing the option for private key requirements for certificates stored in stores with this certificate store type: • *Forbidden*: Private key is not required; generally, applies to trust stores (e.g. Root CA certificates). • *Optional*: Private key is optional; applies to store types that could represent either a Trust Store or End-Entity Store. • *Required*: Private key is required; applies to stores that hold an End-Entity Certificate (server or client authorization). The default value is *Forbidden*.
ServerRequired	Body	A Boolean that indicates whether server access is required for adding certificate stores for this certificate store type (true) or not (false). If set to true, a user will be prompted for a username and password to connect to the remote server. The default is *false*.
PowerShell	Body	A Boolean that indicates whether jobs for the store type are implemented using PowerShell (true) instead of a .NET class or not (false). The default is *false*.
BlueprintAllowed	Body	A Boolean that indicates whether certificate stores of this type will be included when creating or applying blueprints. For more details, see Orchestrator Blueprints on page 475 in the *Keyfactor Command Reference Guide*. The default is *false*.
CustomAliasAllowed	Body	A string containing the selected certificate store type alias option: • *Forbidden*: A custom alias is not required and cannot be supplied. • *Optional*: A custom alias is optional. • *Required*: A custom alias is required. The certificate store alias serves as an identifier for the certificate in the store. Depending on the type of store, it may be a file name, a certificate thumbprint, a string reference, or some other information. Some types of stores may not support associating an alias with the certificate (e.g. IIS trusted root). The default value is *Forbidden*.
EntryParameters	Body	An array of unique parameters that are required when performing management

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>jobs on a certificate store of this type. Entry parameter options include:

If Type is Boolean, this field should contain true or false.
This value is unset by default.</td></tr>
<tr><td>Options</td><td>A string containing a comma-separated list of multiple choice options for this entry parameter. This field should only be populated if Type is set to MultipleChoice.
This value is unset by default.</td></tr>
</table>
For example, to set a multiple choice entry parameter:
<pre>
"EntryParameter": [
   {
      "Name": "ZooAnimal",
      "DisplayName": "Favorite Zoo Animal",
      "Type": "MultipleChoice",
      "RequiredWhen": {
         "HasPrivateKey": false,
         "OnAdd": true,
         "OnRemove": true,
         "OnReenrollment": true
      },
      "DefaultValue": "Penguin",
      "Options": "Tiger,Bear,Giraffe,Lion,Wolf,Penguin,Zebra"
   }
]
</pre>
This value is unset by default.
</td></tr>
</table>

Name	In	Description
		Tip: What's the difference between properties (custom fields) and entry parameters? • Properties are about the certificate store definition itself and are static. For example, you might use a property to define the primary node name of an F5 instance. This node name is the same no matter what inventory or management jobs you do with the F5 device(s). Values for properties are entered in the certificate store record when creating or editing the certificate store record. • Entry parameters are about the specific certificate within the certificate store. They are used to send additional information related to the certificate to the server or device that hosts the certificate store when running management jobs for that certificate store. If Type is Multiple Choice, this field should contain a single value that represents the default selection from the provided list (see Options) for this entry parameter. If Type is Boolean, this field should contain true or false.</td></tr><tr><td>Options</td><td>A string containing a comma-separated list of multiple choice options for this entry parameter.</td></tr></table>

Name	Description
	Tip: What's the difference between properties (custom fields) and entry parameters? • Properties are about the certificate store definition itself and are static. For example, you might use a property to define the primary node name of an F5 instance. This node name is the same no matter what inventory or management jobs you do with the F5 device(s). Values for properties are entered in the certificate store record when creating or editing the certificate store record. • Entry parameters are about the specific certificate within the certificate store. They are used to send additional information related to the certificate to the server or device that hosts the certificate store when running management jobs for that certificate store. Often this is more fluid information that isn't the same for every use of that certificate store. For example, several virtual servers with separate certificates in the same folder may exist on a NetScaler device. When replacing one certificate, updates may need to be made to only the virtual server that is using the certificate. In this case, the authorized user will be prompted to enter the virtual server name based on an entry parameter. Values for entry parameters are entered at the time a management job is initiated (e.g. adding a certificate to a certificate store).
InventoryEndpoint	A string containing the orchestrator endpoint to which inventory updates are sent.
InventoryJobType	A GUID identifying the job type for inventory jobs.
ManagementJobType	A GUID identifying the job type for management jobs.
DiscoveryJobType	A GUID identifying the job type for discovery jobs.
EnrollmentJobType	A GUID identifying the job type for reenrollment jobs.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.11.7 PUT Certificate Store Types

The PUT /CertificateStoreTypes method is used to update a certificate store type in Keyfactor Command. This method returns HTTP 200 OK on a success with a message body containing a list of certificate store type details.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateStoreManagement: *Modify*

Warning: Any previously populated fields that are not submitted with their full existing data using this method will be cleared of their existing data. When using this method, you should first do a GET to retrieve all the values for the record you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing.

Table 298: PUT Certificate Store Types Input Parameters

Name	In	Description
StoreType	Body	**Required**. The Keyfactor Command reference ID for the certificate store type.
Name	Body	**Required**. A string containing the full name of the certificate store type. A unique value must be supplied.
ShortName	Body	**Required**. A string containing the short name assigned to the certificate store type. A unique value must be supplied with a maximum of 10 characters.
Capability	Body	A string containing a reference name for the certificate store type (e.g. NS for a NetScaler store). **Note:** The *Capability* cannot be changed on an edit if an orchestrator has registered with Keyfactor Command, been approved, and included the certificate store type in its capability list.
LocalStore	Body	A Boolean that indicates whether the store is local to the orchestrator machine (true) as, for example, JKS and PEM stores managed by the Keyfactor Java Agent or remote (false) as, for example, IIS stores managed by the Keyfactor Universal Orchestrator. The default is *false*.
SupportedOperations	Body	An array containing a series of Boolean values that indicate whether the certificate store type is enabled for the following functions: • Add • Create • Discovery • Enrollment • Remove The default for each value is *false*.
Properties	Body	An array of unique parameters for the certificate store type. In the Keyfactor Command Management Portal these are known as *Custom Fields*. Property parameters include: **Name** / **Description** StoreTypeID — **Required**. An integer identifying the certificate store type. This is the same ID referenced by the StoreType parameter, above. If you are updating a certificate store type, this field is **required**. Name — **Required**. A string containing the short name of the

Name	In	Description
		<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td>property. If you choose to define a property, this field is **required**.</td></tr><tr><td>DisplayName</td><td>**Required**. A string containing the full display name of the property. If you choose to define a property, this field is **required**.</td></tr><tr><td>Type</td><td>**Required**. A string containing the type of the property: - String - Bool - MultipleChoice - Secret If you choose to define a property, this field is **required**.</td></tr><tr><td>DependsOn</td><td>A string containing the name of the parameter on which this parameter depends. This only applies if at least two custom parameters have been created for this certificate store type. This option is used to configure one custom parameter to display only if another custom parameter contains a value.</td></tr><tr><td>DefaultValue</td><td>A string containing the default value(s) of the parameter. If *Type* is *Multiple Choice*, this field should contain a comma-separated list of multiple choice options for this parameter. If *Type* is *Boolean*, this field should contain *true* or *false*.</td></tr><tr><td>Required</td><td>A Boolean that indicates whether the parameter is required (true) or not (false).</td></tr></table> **Note:** There are three standard properties that are used for any built-in certificate store types that require server credentials (e.g. F5): - ServerUsername - ServerPassword - ServerUseSsl These replace the separate certificate store server records that existed in previous versions of Keyfactor Command. For legacy support, if credentials are not provided through store properties during creation or editing of a certificate store, Keyfactor Command will attempt to

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>find a certificate store server record and copy the credentials from it into the store properties for future use.

For example, to set a multiple choice property:

<pre>"Properties": [
   {
      "StoreTypeId": 111,
      "Name": "Pets",
      "DisplayName": "Popular Pets",
      "Type": "MultipleChoice",
      "DependsOn": "",
      "DefaultValue": "Cat,Dog,Fish,Rat,Mouse",
      "Required": false
   }
]</pre>
This value is unset by default.</td></tr>
<tr><td>PasswordOptions</td><td>Body</td><td>Options for the password in the certificate store type. Password options include:

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>EntrySupported</td><td>A Boolean that indicates whether entry of a password for the certificate in the certificate store is allowed (true) or not (false). The default is false.</td></tr>
<tr><td>StoreRequired</td><td>A Boolean that indicates whether entry of a password on the certificate store as a whole is required (true) or not (false). The default is false.</td></tr>
<tr><td>Style</td><td>A string containing the style of password:
• Default: Keyfactor Command will randomly generate a password.
• Custom: Allow a password to be entered and authenticated when enrolling for a certificate through Keyfactor Command when installing to a store of this type. The Custom option can be selected only if the Allow Custom Password in the Application Settings, is equal to True. For more details, see Application Settings: Enrollment Tab on</td></tr>
</table>
</td></tr>
</table>

Name	In	Description
		<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td>page 560 in the*Keyfactor Command Reference Guide*. The default value is *Default*.</td></tr></table>
StorePathType	Body	A string containing the selected store type: • *Freeform*: Users are required to enter a path defining the certificate store location. • *Fixed*: A store path does not apply, generally one store per device (e.g. IIS). • *MultipleChoice*: Allow a comma separated list of options to be entered that users will be able to select from when defining the certificate store location. This value is unset by default.
StorePathValue	Body	An array containing the value(s) for the certificate store path if the *StorePathType* is set to Fixed or Multiple Choice. Multiple choice values should be provided in a bracketed comma-delimited list like so: `"StorePathValue": "[\"Apple\",\"Cherry\",\"Peach\",\"Pear\"]"` This value is unset by default.
PrivateKeyAllowed	Body	A string containing the option for private key requirements for certificates stored in stores with this certificate store type: • *Forbidden*: Private key is not required; generally, applies to trust stores (e.g. Root CA certificates). • *Optional*: Private key is optional; applies to store types that could represent either a Trust Store or End-Entity Store. • *Required*: Private key is required; applies to stores that hold an End-Entity Certificate (server or client authorization). The default value is *Forbidden*.
ServerRequired	Body	A Boolean that indicates whether server access is required for adding certificate stores for this certificate store type (true) or not (false). If set to true, a user will be prompted for a username and password to connect to the remote server. The default is *false*.
PowerShell	Body	A Boolean that indicates whether jobs for the store type are implemented using PowerShell (true) instead of a .NET class or not (false). The default is *false*.
BlueprintAllowed	Body	A Boolean that indicates whether certificate stores of this type will be included

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>when creating or applying blueprints. For more details, see Orchestrator Blueprints on page 475 in the Keyfactor Command Reference Guide. The default is false.</td></tr>
<tr><td>CustomAliasAllowed</td><td>Body</td><td>A string containing the selected certificate store type alias option:
Forbidden: A custom alias is not required and cannot be supplied.
Optional: A custom alias is optional.
Required: A custom alias is required.
The certificate store alias serves as an identifier for the certificate in the store. Depending on the type of store, it may be a file name, a certificate thumbprint, a string reference, or some other information. Some types of stores may not support associating an alias with the certificate (e.g. IIS trusted root).
The default value is Forbidden.</td></tr>
<tr><td>EntryParameters</td><td>Body</td><td>An array of unique parameters that are required when performing management jobs on a certificate store of this type. Entry parameter options include:<table><tr><th>Name</th><th>Description</th></tr><tr><td>StoreTypeID</td><td>Required. An integer identifying the certificate store type. This is the same ID referenced by the StoreType parameter, above. If you are updating a certificate store type, this field is required.</td></tr><tr><td>Name</td><td>Required. A string containing the short name of the entry parameter. If you choose to define an entry parameter, this field is required. The name should be entered without spaces.</td></tr><tr><td>DisplayName</td><td>Required. A string containing the full display name of the entry parameter. If you choose to define an entry parameter, this field is required.</td></tr><tr><td>Type</td><td>Required. A string containing the type of the entry parameter:
String
Bool
MultipleChoice
Secret
If you choose to define an entry parameter, this field is required.</td></tr></table></td></tr>
</table>

Name	In	Description
		<table><tr><th>Name</th><th>Description</th></tr><tr><td>RequiredWhen</td><td>An array of Boolean values indicating the circumstances under which a value is required to be provided for this entry parameter. These are: **HasPrivateKey**: If set to *true*, a value must be provided for this field when configuring a management job (either add or remove) if the certificate has an associated private key in Keyfactor Command. This would be the case, for example, when doing a PFX enrollment and adding the resulting certificate to a certificate store. The default is *false*. **OnAdd**: If set to *true*, a value must be provided for this field when configuring an add certificate job. The default is *false*. **OnRemove**: If set to *true*, a value must be provided for this field when configuring a remove certificate job. The default is *false*. **OnReenrollment**: If set to *true*, a value must be provided for this field when configuring a reenrollment job. The default is *false*. </td></tr><tr><td>DependsOn</td><td>A string containing the name of the parameter on which this parameter depends. This only applies if at least two custom parameters have been created for this certificate store type. This option is used to configure one custom parameter to display only if another custom parameter contains a value.</td></tr><tr><td>DefaultValue</td><td>A string containing the default value for the entry parameter. If *Type* is *Multiple Choice*, this field should contain a single value that represents the default selection from the provided list (see Options) for this entry parameter. If *Type* is *Boolean*, this field should contain *true* or *false*. This value is unset by default.</td></tr><tr><td>Options</td><td>A string containing a comma-separated list of multiple choice options for this entry parameter. This field should only be populated if *Type* is set to *MultipleChoice*. This value is unset by default.</td></tr></table>

Name	In	Description
		For example, to set a multiple choice entry parameter: `"EntryParameter": [{ "StoreTypeId": 111, "Name": "ZooAnimal", "DisplayName": "Favorite Zoo Animal", "Type": "MultipleChoice", "RequiredWhen": { "HasPrivateKey": false, "OnAdd": true, "OnRemove": true, "OnReenrollment": true }, "DefaultValue": "Penguin", "Options": "Tiger,Bear,Giraffe,Lion,Wolf,Penguin,Zebra" }]` This value is unset by default. **Tip:** What's the difference between properties (custom fields) and entry parameters? • Properties are about the certificate store definition itself and are static. For example, you might use a property to define the primary node name of an F5 instance. This node name is the same no matter what inventory or management jobs you do with the F5 device(s). Values for properties are entered in the certificate store record when creating or editing the certificate store record. • Entry parameters are about the specific certificate within the certificate store. They are used to send additional information related to the certificate to the server or device that hosts the certificate store when running management jobs for that certificate store. Often this is more fluid information that isn't the same for every use of that certificate store. For example, several virtual servers with separate certificates in the same folder may exist on a NetScaler device. When replacing one certificate, updates may need to be made to only the virtual server that is using the certificate. In this case, the authorized user will be prompted to enter the virtual server name based on an entry parameter. Values for entry parameters are entered at the time a management job is initiated (e.g. adding a certificate to a certificate store).

Table 299: PUT Certificate Store Types Response Data

Name	Description
Name	A string containing the full name of the certificate store type.
ShortName	A string containing the short name assigned to the certificate store type.
Capability	A string containing a reference name for the certificate store type (e.g. NS for a NetScaler store).
StoreType	A unique integer for the certificate store type. The ID is automatically assigned by Keyfactor Command.
ImportType	An integer that indicates the import type for the certificate store type. The ID is automatically assigned by Keyfactor Command and generally matches the *StoreType* for custom certificate store types.
LocalStore	A Boolean that indicates whether the store is local to the orchestrator machine (true) as, for example, JKS and PEM stores managed by the Keyfactor Java Agent or remote (false) as, for example, IIS stores managed by the Keyfactor Universal Orchestrator.
SupportedOperations	An array containing a series of Boolean values that indicate whether the certificate store type is enabled for the following functions: • Add • Create • Discovery • Enrollment • Remove
Properties	An array of unique parameters for the certificate store type. In the Keyfactor Command Management Portal these are known as *Custom Fields*. Property parameters include:

Name	Description
Name	A string containing the short name of the property.
DisplayName	A string containing the full display name of the property.
Type	A string containing the type of the property: • String • Bool • MultipleChoice • Secret

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>DependsOn</td><td>A string containing the name of the parameter on which this parameter depends. This only applies if at least two custom parameters have been created for this certificate store type. This option is used to configure one custom parameter to display only if another custom parameter contains a value.</td></tr>
<tr><td>DefaultValue</td><td>A string containing the default value(s) of the parameter. If Type is Multiple Choice, this field should contain a comma-separated list of multiple choice options for this parameter. If Type is Boolean, this field should contain true or false.</td></tr>
<tr><td>Required</td><td>A Boolean that indicates whether the parameter is required (true) or not (false).</td></tr>
</table>

Note: There are three standard properties that are used for any built-in certificate store types that require server credentials (e.g. F5):

ServerUsername
ServerPassword
ServerUseSsl

These replace the separate certificate store server records that existed in previous versions of Keyfactor Command. For legacy support, if credentials are not provided through store properties during creation or editing of a certificate store, Keyfactor Command will attempt to find a certificate store server record and copy the credentials from it into the store properties for future use.
</td></tr>
<tr><td>PasswordOptions</td><td>Options for the password in the certificate store type. Password options include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>EntrySupported</td><td>A Boolean that indicates whether entry of a password for the certificate in the certificate store is allowed (true) or not (false).</td></tr>
<tr><td>StoreRequired</td><td>A Boolean that indicates whether entry of a password on the certificate store as a whole is required (true) or not (false).</td></tr>
<tr><td>Style</td><td>A string containing the style of password:

Default: Keyfactor Command will randomly generate a password.
Custom: Allow a password to be entered and authen-

</td></tr>
</table>
</td></tr>
</table>

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td>ticated when enrolling for a certificate through Keyfactor Command when installing to a store of this type. The Custom option can be selected only if the *Allow Custom Password* in the Application Settings, is equal to *True*. For more details, see Application Settings: Enrollment Tab on page 560 in the*Keyfactor Command Reference Guide*.</td></tr></table>
StorePathValue	An array containing the value(s) for the certificate store path.
PrivateKeyAllowed	A string containing the option for private key requirements for certificates stored in stores with this certificate store type: • *Forbidden*: Private key is not required; generally, applies to trust stores (e.g. Root CA certificates). • *Optional*: Private key is optional; applies to store types that could represent either a Trust Store or End-Entity Store. • *Required*: Private key is required; applies to stores that hold an End-Entity Certificate (server or client authorization).
ServerRequired	A Boolean that indicates whether server access is required for adding certificate stores for this certificate store type (true) or not (false). If set to true, a user will be prompted for a user-name and password to connect to the remote server.
PowerShell	A Boolean that indicates whether jobs for the store type are implemented using PowerShell (true) instead of a .NET class or not (false).
BlueprintAllowed	A Boolean that indicates whether certificate stores of this type will be included when creating or applying blueprints. For more details, see Orchestrator Blueprints on page 475 in the *Keyfactor Command Reference Guide*.
CustomAliasAllowed	A string containing the selected certificate store type alias option: • *Forbidden*: A custom alias is not required and cannot be supplied. • *Optional*: A custom alias is optional. • *Required*: A custom alias is required. The certificate store alias serves as an identifier for the certificate in the store. Depending on the type of store, it may be a file name, a certificate thumbprint, a string reference, or some other information. Some types of stores may not support associating an alias with the certificate (e.g. IIS trusted root).
EntryParameters	An array of unique parameters that are required when performing management jobs on a certificate store of this type. Entry parameter options include:

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td>Name</td><td>A string containing the short name of the entry parameter.</td></tr><tr><td>DisplayName</td><td>A string containing the full display name of the entry parameter.</td></tr><tr><td>Type</td><td>A string containing the type of the entry parameter: - String - Bool - MultipleChoice - Secret </td></tr><tr><td>RequiredWhen</td><td>An array of Boolean values indicating the circumstances under which a value is required to be provided for this entry parameter. These are: - HasPrivateKey: If set to true, a value must be provided for this field when configuring a management job (either add or remove) if the certificate has an associated private key in Keyfactor Command. This would be the case, for example, when doing a PFX enrollment and adding the resulting certificate to a certificate store. - OnAdd: If set to true, a value must be provided for this field when configuring an add certificate job. - OnRemove: If set to true, a value must be provided for this field when configuring a remove certificate job. - OnReenrollment: If set to true, a value must be provided for this field when configuring a reenrollment job. </td></tr><tr><td>DependsOn</td><td>A string containing the name of the parameter on which this parameter depends. This only applies if at least two custom parameters have been created for this certificate store type. This option is used to configure one custom parameter to display only if another custom parameter contains a value.</td></tr><tr><td>DefaultValue</td><td>A string containing the default value for the entry parameter. If Type is Multiple Choice, this field should contain a single value that represents the default selection from the provided list (see Options) for this entry parameter. If Type is Boolean, this field should contain true or false.</td></tr><tr><td>Options</td><td>A string containing a comma-separated list of multiple choice options for this entry parameter.</td></tr></table>

Name	Description
	Tip: What's the difference between properties (custom fields) and entry parameters? • Properties are about the certificate store definition itself and are static. For example, you might use a property to define the primary node name of an F5 instance. This node name is the same no matter what inventory or management jobs you do with the F5 device(s). Values for properties are entered in the certificate store record when creating or editing the certificate store record. • Entry parameters are about the specific certificate within the certificate store. They are used to send additional information related to the certificate to the server or device that hosts the certificate store when running management jobs for that certificate store. Often this is more fluid information that isn't the same for every use of that certificate store. For example, several virtual servers with separate certificates in the same folder may exist on a NetScaler device. When replacing one certificate, updates may need to be made to only the virtual server that is using the certificate. In this case, the authorized user will be prompted to enter the virtual server name based on an entry parameter. Values for entry parameters are entered at the time a management job is initiated (e.g. adding a certificate to a certificate store).
InventoryEndpoint	A string containing the orchestrator endpoint to which inventory updates are sent.
InventoryJobType	A GUID identifying the job type for inventory jobs.
ManagementJobType	A GUID identifying the job type for management jobs.
DiscoveryJobType	A GUID identifying the job type for discovery jobs.
EnrollmentJobType	A GUID identifying the job type for reenrollment jobs.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.12 CSR Generation

The CSR Generation component of the Keyfactor API includes methods necessary to generate certificate signing requests and determine which ones are pending.

Table 300: CSR Generation Endpoints

Endpoint	Method	Description	Link
/Pending/{id}	DELETE	Deletes a pending CSR by ID.	DELETE CSR Generation Pending ID below
/Pending/{id}	GET	Returns the details of a specific CSR request based on the ID number.	GET CSR Generation Pending ID below
/Pending	DELETE	Deletes multiple pending CSRs.	DELETE CSR Generation Pending on the next page
/Pending	GET	Returns a list of all pending CSRs.	GET CSR Generation Pending on page 1275
/Generate	POST	Generate and configure a CSR request.	POST CSR Generation Generate on page 1276

3.2.12.1 DELETE CSR Generation Pending ID

The DELETE /CSRGeneration/Pending/{id} method is used to delete a certificate signing request with the defined ID that has not yet been enrolled. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: CertificateEnrollment: *PendingCsr*

Table 301: DELETE CSR Generation Pending {id} Input Parameters

Name	In	Description
id	Path	**Required**. The ID of the certificate signing request for the CSR that should be deleted. Use the *GET /CSRGeneration/Pending* method (see GET CSR Generation Pending on page 1275) to retrieve a list of all the pending CSRs to determine the CSR IDs.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.12.2 GET CSR Generation Pending ID

The GET /CSRGeneration/Pending/{id} method is used to return a generated CSR with the defined ID that has not yet been enrolled. This method returns HTTP 200 OK on a success with the CSR in PEM format. This method does not return the parsed subject name or CSR request time. If you need that information, use the *GET /CSRGeneration/Pending* method (see GET CSR Generation Pending on page 1275).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: CertificateEnrollment: *PendingCsr*

Table 302: GET CSR Generation Pending {id} Input Parameters

Name	In	Description
id	Path	**Required**. The ID of the CSR that should be retrieved.

Table 303: GET CSR Generation Pending {id} Response Data

Name	Description
CSRFilePath	The proposed file name for the CSR file. This is considered deprecated and may be removed in a future release.
CSR	The text of the CSR in PEM format.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.12.3 DELETE CSR Generation Pending

The DELETE /CSRGeneration/Pending method is used to delete multiple certificate signing requests that have not yet been enrolled in one request. The IDs should be supplied in the request body as a JSON array of integers. Delete operations will continue until the entire array of IDs has been processed. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: CertificateEnrollment: *PendingCsr*

Table 304: DELETE CSR Generation Pending Input Parameters

Name	In	Description
ids	Body	**Required**. An array of Keyfactor Command certificate signing request IDs for CSRs that should be deleted in the form (without parameter name): `[8,14,27]` Use the *GET /CSRGeneration/Pending* method (see GET CSR Generation Pending on the next page) to retrieve a list of all the pending CSRs to determine the CSR IDs.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.12.4 GET CSR Generation Pending

The GET /CSRGeneration/Pending method is used to return details for generated CSRs that have not yet been enrolled. This method returns HTTP 200 OK on a success with details of the pending CSRs with details.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: CertificateEnrollment: *PendingCsr*

Table 305: GET CSR Generation Pending Input Parameters

Name	In	Description
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *Id*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 306: GET CSR Generation Pending Response Data

Name	Description
Id	A unique integer for the CSR generated.
CSR	A string containing the text of the CSR in PEM format.
RequestTime	A string containing the date and time that the CSR was generated in UTC time.
Subject	An array containing the subject of the certificate including the certificate subject information, the subject alternative names, the key length, and the hash algorithm.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.12.5 POST CSR Generation Generate

The POST /CSRGeneration/Generate method is used to generate and configure a CSR. This method returns HTTP 200 OK on a success with a message body containing the text of the CSR file created.

This method generates a private key and stores it in the Keyfactor Command database. When you use the CSR resulting from this method to enroll for a certificate through Keyfactor Command (see POST Enrollment CSR on page 1326), the resulting certificate is married together with the stored private key and may then be download with private key (see POST Certificates Recover on page 986).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateEnrollment: *CsrGeneration*

Note: This endpoint no longer includes the CSRFilePath return value in the response from the API call. Code separate from the API should be used to handle receipt of the CSR and placement on the file system.

Table 307: POST CSR Generation Generate Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>Subject</td><td>Body</td><td>Required. A string containing the subject name for the certificate using X.500 format for the full distinguished name (DN). For example:
<pre>"Subject": "CN=websrvr14.keyexample.com,OU=IT,O=\"Key Example, Inc.\",L-L=Independence,ST=OH,C=US"</pre>Supported subject name fields are:
<table>
<tr><th>Name</th><th>Abbreviation</th><th>Description</th></tr>
<tr><td>CommonName</td><td>CN</td><td>Required*. The desired common name of the certificate to be requested with the CSR.
This field is required if the Common Name Regular Expression application setting is set to the default value of .+. See Application Settings: Enrollment Tab on page 560 in the Keyfactor Command Reference Guide for more information.</td></tr>
<tr><td>Organization</td><td>O</td><td>The desired organization of the certificate to be requested with the CSR.</td></tr>
<tr><td>OrganizationalUnit</td><td>OU</td><td>The desired organizational unit of the certificate to be requested with the CSR.</td></tr>
<tr><td>Locality</td><td>L</td><td>The desired city of the certificate to be requested with the CSR.</td></tr>
<tr><td>State</td><td>ST</td><td>The desired state of the certificate to be requested with the CSR.</td></tr>
<tr><td>Country</td><td>C</td><td>The desired country (two characters) of the certificate to be requested with the CSR.</td></tr>
<tr><td>Email</td><td>E</td><td>The desired email address of the certificate to be requested with the CSR.</td></tr>
</table></td></tr>
<tr><td>KeyType</td><td>Body</td><td>Required. A string indicating the desired key encryption of the certificate. Accepted key types are:
• RSA</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>ECC</td></tr>
<tr><td>KeyLength</td><td>Body</td><td>Required. An integer indicating the desired key size of the certificate. Accepted key sizes are:
256
384
521
2048
4096
8192</td></tr>
<tr><td>Template</td><td>Body</td><td>A string indicating the desired template to be used for the certificate to be requested with the CSR. The template must have been configured in Keyfactor Command to support CSR generation. This field is optional.

Tip: Although you can include a template in your CSR, template handling in CSRs is future functionality, and the template will not be parsed back out of the CSR. Instead, submit a template directly with your CSR enrollment (see POST Enrollment CSR on page 1326).</td></tr>
<tr><td>SANs</td><td>Body</td><td>An array of key/value pairs that represent the elements for Keyfactor Command to use when generating the subject alternative name (SAN) for the certificate requested by the CSR. Possible values for the key are:<table><tr><th>Value</th><th>Description</th></tr><tr><td>rfc822</td><td>RFC 822 Name</td></tr><tr><td>dns</td><td>DNS Name</td></tr><tr><td>directory</td><td>Directory Name</td></tr><tr><td>uri</td><td>Uniform Resource Identifier</td></tr><tr><td>ip4</td><td>IP v4 Address</td></tr><tr><td>ip6</td><td>IP v6 Address</td></tr><tr><td>registeredid</td><td>Registered ID (an OID)</td></tr><tr><td>ms_ntprincipalname</td><td>MS_NTPrincipalName (a string)</td></tr><tr><td>ms_ntdsreplication</td><td>MS_NTDSReplication (a GUID)</td></tr></table>For example:</td></tr>
</table>

Name	In	Description

		<pre>"SANs": {
		  "dns": [
		  "dnssan1.keyexample.com",
		  "dnssan2.keyexample.com",
		  "dnssan3.keyexample.com"
		  ],
		  "ip4": [
		  "192.168.2.73"
		  ]
		}</pre>

Table 308: POST CSR Generation Generate Response Data

Name	Description
CSR	The text of the CSR in PEM format.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.13 Custom Job Types

The Custom Job Types component of the Keyfactor API includes methods necessary to create, update, list and delete custom orchestrator job types. Custom job types are intended to execute jobs on an orchestrator built using the AnyAgent framework that are outside the standard list of job functions built into Keyfactor Command. This powerful feature can execute just about any job that requires processing on the orchestrator and submitting data back to Keyfactor Command. The data submitted by custom jobs to Keyfactor Command is stored as a string and is limited to 2 MB.

Table 309: Custom Job Types Endpoints

Endpoint	Method	Description	Link
/{id}	DELETE	Deletes the custom job type for the specified ID.	DELETE Custom Job Types ID on the next page
/{id}	GET	Returns details for the custom job type for the specified ID.	GET Custom Job Types ID on the next page
/	GET	Returns all the custom job types.	GET Custom Job Types on page 1281
/	POST	Creates a custom job type.	POST Custom Job Types on

Endpoint	Method	Description	Link
			page 1283
/	PUT	Updates an existing custom job type.	PUT Custom Job Types on page 1287

3.2.13.1 DELETE Custom Job Types ID

The DELETE /JobTypes/Custom/{id} method is used to delete an existing custom job type with the specified GUID. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: AgentManagement: *Modify*

Table 310: DELETE JobTypes Custom {id} Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference GUID of the custom job type. Use the *GET /JobTypes/Custom* method (see GET Custom Job Types on the next page) to retrieve a list of all the custom job types to determine the job type GUID.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.13.2 GET Custom Job Types ID

The GET /JobTypes/Custom/{id} method is used to return a custom job type with the specified GUID. This method returns HTTP 200 OK on a success with details for the custom job type.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: AgentManagement: *Read*

Table 311: GET JobTypes Custom {id} Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference GUID of the custom job type. Use the *GET /JobTypes/Custom* method (see GET Custom Job Types on the next page) to retrieve a list of all the custom job types to determine the job type GUID.

Table 312: GET JobTypes Custom {id} Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>The Keyfactor Command reference GUID for the custom job type. This ID is automatically set by Keyfactor Command.</td></tr>
<tr><td>JobTypeName</td><td>A string containing the short name for the custom job type. This is used to reference the job type when submitting a job for it.</td></tr>
<tr><td>Description</td><td>A string containing a description for the custom job type.</td></tr>
<tr><td>JobTypeFields</td><td>An array of job type fields that indicate the type of tasks the job type is designed to perform. Job type fields parameters are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Name</td><td>A string that indicates the name for the job type field.</td></tr>
<tr><td>Type</td><td>A value that indicates the data type of the job type field.
Possible values are:
<table>
<tr><th>Integer Value</th><th>Enum Value</th><th>Description</th></tr>
<tr><td>1</td><td>String</td><td>String</td></tr>
<tr><td>2</td><td>Int</td><td>Integer</td></tr>
<tr><td>3</td><td>DateTime</td><td>Date</td></tr>
<tr><td>4</td><td>Bool</td><td>Boolean</td></tr>
</table></td></tr>
<tr><td>DefaultValue</td><td>A string containing the default value of the job type field.
If Type is Boolean, this field should contain true or false.</td></tr>
<tr><td>Required</td><td>A Boolean that sets whether the job type field is required (true) or not (false).</td></tr>
</table></td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon () at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.13.3 GET Custom Job Types

The GET /JobTypes/Custom method is used to retrieve a list of all custom job types. This method returns HTTP 200 OK on a success with details for each job type.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
AgentManagement: *Read*

Table 313: GET JobTypes Custom Input Parameters

Name	In	Description
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.

Table 314: GET JobTypes Custom Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>The Keyfactor Command reference GUID for the custom job type. This ID is automatically set by Keyfactor Command.</td></tr>
<tr><td>JobTypeName</td><td>A string containing the short name for the custom job type. This is used to reference the job type when submitting a job for it.</td></tr>
<tr><td>Description</td><td>A string containing a description for the custom job type.</td></tr>
<tr><td>JobTypeFields</td><td>An array of job type fields that indicate the type of tasks the job type is designed to perform. Job type fields parameters are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Name</td><td>A string that indicates the name for the job type field.</td></tr>
<tr><td>Type</td><td>A value that indicates the data type of the job type field.
Possible values are:
<table>
<tr><th>Integer Value</th><th>Enum Value</th><th>Description</th></tr>
<tr><td>1</td><td>String</td><td>String</td></tr>
<tr><td>2</td><td>Int</td><td>Integer</td></tr>
<tr><td>3</td><td>DateTime</td><td>Date</td></tr>
<tr><td>4</td><td>Bool</td><td>Boolean</td></tr>
</table></td></tr>
<tr><td>DefaultValue</td><td>A string containing the default value of the job type field.
If Type is Boolean, this field should contain true or false.</td></tr>
<tr><td>Required</td><td>A Boolean that sets whether the job type field is required (true) or not (false).</td></tr>
</table></td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon () at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.13.4 POST Custom Job Types

The POST /JobTypes/Custom method is used to create a custom orchestrator job type in Keyfactor Command. This method returns HTTP 200 OK on a success with a message body containing a list of custom job type details.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: AgentManagement: *Modify*

Table 315: POST JobTypes Custom Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>JobTypeName</td><td>Body</td><td>Required. A string containing the short name for the custom job type. This is used to reference the job type when submitting a job for it. This name should not contain spaces.</td></tr>
<tr><td>Description</td><td>Body</td><td>A string containing a description for the custom job type.</td></tr>
<tr><td>JobTypeFields</td><td>Body</td><td>An array of job type fields that indicate the type of tasks the job type is designed to perform. Job type fields parameters are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Name</td><td>Required. A string that indicates the name for the job type field.</td></tr>
<tr><td>Type</td><td>Required. A value that indicates the data type of the job type field.
It may be entered as either an integer or the matching enum value. Possible values are:
<table>
<tr><th>Integer Value</th><th>Enum Value</th><th>Description</th></tr>
<tr><td>1</td><td>String</td><td>String</td></tr>
<tr><td>2</td><td>Int</td><td>Integer</td></tr>
<tr><td>3</td><td>DateTime</td><td>Date</td></tr>
<tr><td>4</td><td>Bool</td><td>Boolean</td></tr>
</table></td></tr>
<tr><td>DefaultValue</td><td>Required*. A string containing the default value of the job type field.
If Type is Boolean, this field should contain true or false.
This field is required if the Required parameter is set to true.</td></tr>
<tr><td>Required</td><td>A Boolean that sets whether the job type field is required (true) or not (false). The default is false.</td></tr>
</table>
For example:
<pre>
"JobTypeFields": [
  {
    "Name": "Favorite Type of Pet",
</pre></td></tr>
</table>

Name	In	Description

		"Type": "String",
		"DefaultValue": "Cat",
		"Required": true
		},
		{
		"Name": "Model Year of First Car",
		"Type": "Int"
		},
		{
		"Name": "Mother's Birthday",
		"Type": "DateTime"
		}
		]

Table 316: POST JobTypes Custom Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>The Keyfactor Command reference GUID for the custom job type. This ID is automatically set by Keyfactor Command.</td></tr>
<tr><td>JobTypeName</td><td>A string containing the short name for the custom job type. This is used to reference the job type when submitting a job for it.</td></tr>
<tr><td>Description</td><td>A string containing a description for the custom job type.</td></tr>
<tr><td>JobTypeFields</td><td>An array of job type fields that indicate the type of tasks the job type is designed to perform. Job type fields parameters are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Name</td><td>A string that indicates the name for the job type field.</td></tr>
<tr><td>Type</td><td>A value that indicates the data type of the job type field.
Possible values are:
<table>
<tr><th>Integer Value</th><th>Enum Value</th><th>Description</th></tr>
<tr><td>1</td><td>String</td><td>String</td></tr>
<tr><td>2</td><td>Int</td><td>Integer</td></tr>
<tr><td>3</td><td>DateTime</td><td>Date</td></tr>
<tr><td>4</td><td>Bool</td><td>Boolean</td></tr>
</table></td></tr>
<tr><td>DefaultValue</td><td>A string containing the default value of the job type field.
If Type is Boolean, this field should contain true or false.</td></tr>
<tr><td>Required</td><td>A Boolean that sets whether the job type field is required (true) or not (false).</td></tr>
</table></td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.13.5 PUT Custom Job Types

The PUT /JobTypes/Custom method is used to create a custom orchestrator job type in Keyfactor Command. This method returns HTTP 200 OK on a success with a message body containing a list of certificate store type details.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: AgentManagement: *Modify*

Warning: Any previously populated fields that are not submitted with their full existing data using this method will be cleared of their existing data. When using this method, you should first do a GET to retrieve all the values for the record you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing.

Table 317: PUT JobTypes Custom Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>Id</td><td>Body</td><td>The Keyfactor Command reference GUID for the custom job type. This ID is automatically set by Keyfactor Command.</td></tr>
<tr><td>JobTypeName</td><td>Body</td><td>Required. A string containing the short name for the custom job type. This is used to reference the job type when submitting a job for it. This name should not contain spaces.</td></tr>
<tr><td>Description</td><td>Body</td><td>A string containing a description for the custom job type.</td></tr>
<tr><td>JobTypeFields</td><td>Body</td><td>An array of job type fields that indicate the type of tasks the job type is designed to perform. Job type fields parameters are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Name</td><td>Required. A string that indicates the name for the job type field.</td></tr>
<tr><td>Type</td><td>Required. A value that indicates the data type of the job type field.
It may be entered as either an integer or the matching enum value. Possible values are:
<table>
<tr><th>Integer Value</th><th>Enum Value</th><th>Description</th></tr>
<tr><td>1</td><td>String</td><td>String</td></tr>
<tr><td>2</td><td>Int</td><td>Integer</td></tr>
<tr><td>3</td><td>DateTime</td><td>Date</td></tr>
<tr><td>4</td><td>Bool</td><td>Boolean</td></tr>

</table></td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon () at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.14 Enrollment

The Enrollment component of the Keyfactor API includes methods necessary to enroll certificate signing requests (CSRs) and personal information exchanges (PFXs).

Table 319: Enrollment Endpoints

Endpoint	Method	Description	Link
/Settings/{Id}	GET	Returns the template settings to use during enrollment.	GET Enrollment Settings ID below
/CSR/Context/My	GET	Returns the templates available for CSR enrollment by the current user.	GET Enrollment CSR Content My on page 1299
/PFX/Context/My	GET	Returns the templates available for PFX enrollment by the current user.	GET Enrollment PFX Content My on page 1311
/AvailableRenewal/Id/{id}	GET	Returns the type of renewals available for the referenced certificate ID.	GET Enrollment Available Renewal ID on page 1323
/AvailableRenewal/Thumbprint/{thumbprint}	GET	Returns the type of renewals available for the referenced certificate thumbprint.	GET Enrollment Available Renewal Thumbprint on page 1324
/CSR	POST	Performs a CSR enrollment.	POST Enrollment CSR on page 1326
/PFX	POST	Performs a PFX enrollment.	POST Enrollment PFX on page 1332
/CSR/Parse	POST	Returns information found in a CSR in a human friendly form.	POST Enrollment CSR Parse on page 1345
/PFX/Deploy	POST	Adds a certificate into a certificate store following a PFX enrollment or certificate renewal.	POST Enrollment PFX Deploy on page 1347
/PFX/Replace	POST	Replaces a certificate in a certificate store following a PFX enrollment.	POST Enrollment PFX Replace on page 1352
/Renew	POST	Performs a certificate renewal.	POST Enrollment Renew on page 1355

3.2.14.1 GET Enrollment Settings ID

The GET /Enrollment/Settings/{id} method is used to return the template settings to use during enrollment for a given template. The response will be the resolved values for the template settings (based on whether they are global or template-specific). This method returns HTTP 200 OK on a success with details of the template regular expressions, defaults, and policy. If there is a template-specific setting, the template-specific setting will be shown in the response. If there is not a template-specific setting, the global settings will be shown in the response.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: CertificateEnrollment: *EnrollCSR* or CertificateEnrollment: *EnrollPFX* or CertificateEnrollment: *CsrGeneration*

Table 320: GET Enrollment Settings {id} Input Parameters

Name	Description
id	The enrollment template Id. Use the *GET /Templates* method (see GET Templates on page 1922) to retrieve a list of all the templates to determine the template ID.

Table 321: GET Enrollment Settings {id} Response Body

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>TemplateRegexes</td><td>An object containing the regular expressions resolved for the template. Regular expression details are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>SubjectPart</td><td>A string indicating the portion of the subject the regular expression applies to (e.g. CN).</td></tr>
<tr><td>RegEx</td><td>A string specifying the regular expression against which data entered in the indicated subject part field (e.g. CN) in the enrollment pages of the Keyfactor Command Management Portal or using an API enrollment method will be validated.
Use the GET /Templates/SubjectParts method (see <a>GET Templates Subject Parts on page 1921) to retrieve a list of all the supported subject parts.
The following are some regular expression examples:
<table>
<tr><th>Subject Part</th><th>Example</th></tr>
<tr><td>CN (Common Name)</td><td>This regular expression specifies that the data entered in the field must consist of some number of characters in the first portion of the field made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly ".keyexample.com":
<code>^[a-zA-Z0-9'_
\.\-]*\.keyexample\.com$</code>
The default value for the Common Name regular expression is:
<code>.+</code>
This requires entry of at least one character in the Common Name field in the enrollment pages.</td></tr>
<tr><td>O (Organization)</td><td>This regular expression requires that the organization name entered in the field be one of "Key Example Inc", "Key Example" or "Key Example Inc.":
<code>^(?:Key Example Inc|Key Example|Key Example, Inc\.)$</code>
The period in the final company name (Key Example, Inc.) needs to be escaped in the regular expression</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Name	Description
	Name / **Description**

Name

Description

Subject Part	Example
	with a slash ("\") but the comma does not.
OU (Organization Unit)	This regular expression requires that the organizational unit entered in the field be one of these four departments: `^(?:IT|HR|Accounting|E-Commerce)$`
L (City/Locality)	This regular expression requires that the city entered in the field be one of these five cities: `^(?:Boston|Chicago|New York|London|Dallas)$`
ST (State/Province)	This regular expression requires that the state entered in the field be one of these eight states: `^(?:Massachusetts|Illinois|New York|Ontario|Texas)$`
C (Country)	This regular expression requires that the country entered in the field be either US or CA: `^(?:US|CA)$`
E (Email)	This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly "@keyexample.com": `^[a-zA-Z0-9'_\.\-]*@keyexample\.com$`
DNS (Subject Alternative Name: DNS Name)	This regular expression specifies that the data entered in the field must consist of some number of characters in the first portion of the field made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly either ".keyexample1.com" or ".keyexample2.com": `^[a-zA-Z0-9'_\.\-]*\.`

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Subject Part</th><th>Example</th></tr>
<tr><td></td><td><pre>(?:keyexample1\.com|keyexample2\.com)$</pre></td></tr>
<tr><td>IPv4 (Subject Alternative Name: IPv4 Address)</td><td>This regular expression specifies that the data entered in the field must be exactly "130.101." followed by anywhere between 1 and 3 numbers followed by exactly "." followed by anywhere between 1 and 3 numbers:<pre>^130\.101\.(?:[0-9]{1,3})\.(?:[0-9]{1,3})$</pre>This regular expression specifies only that the IPv4 address is made up of 4 sets of between 1 and 3 numbers separated by periods:<pre>^(?:[0-9]{1,3}\.){3}[0-9]{1,3}$</pre></td></tr>
<tr><td>IPv6 (Subject Alternative Name: IPv6 Address)</td><td>This regular expression specifies that the data entered in the field must be made up of eight sets of between one and four numbers and/or uppercase letters separated by colons:<pre>^(?:[A-F0-9]{1,4}:){7}[A-F0-9]{1,4}$</pre></td></tr>
<tr><td>MAIL (Subject Alternative Name: Email)</td><td>This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lower-case letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly "@keyexample.com":<pre>^[a-zA-Z0-9'_\.\-]*@keyexample\.com$</pre></td></tr>
<tr><td>UPN (Subject Alternative Name: User Principal Name)</td><td>This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lower-case letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly "@keyexample.com":<pre>^[a-zA-Z0-9'_\.\-]*@keyexample\.com$</pre></td></tr>
</table>
</td></tr>
<tr><td>Error</td><td>A string specifying the error message displayed to the user when the subject</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>part referenced in the CSR or entered for a PFX enrollment does not match the given regular expression. Note that the error message already includes a leading string with the subject part (e.g. "Common Name:" or "Invalid CN provided:" depending on the interface used). Your custom message follows this.</td></tr>
</table>
</td></tr>
<tr><td>TemplateDefaults</td><td>An object containing the template defaults resolved for the template. Template-level defaults, if defined, take precedence over global-level template defaults. For more information about global-level template defaults, see GET Templates Settings on page 1902. The template default object contains the following parameters:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>SubjectPart</td><td>A string indicating the portion of the subject the default applies to (e.g. L for City/Locality).
Use the GET /Templates/SubjectParts method (see GET Templates Subject Parts on page 1921) to retrieve a list of all the supported subject parts.</td></tr>
<tr><td>Value</td><td>A string containing the value to assign as the default for that subject part (e.g. Chicago).</td></tr>
</table>
For example:
<pre>
"TemplateDefaults": [
   {
      "SubjectPart": "L",
      "Value": "Denver"
   },
   {
      "SubjectPart": "ST",
      "Value": "Colorado"
   }
]
</pre>
</td></tr>
<tr><td>TemplatePolicy</td><td>An array containing the template policy settings. The template policy array contains the following parameters:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>RSAValidKeySizes</td><td>An object containing a comma-delimited list of integers defining the valid RSA key sizes supported for all templates used for enrollment. The supported values are:</td></tr>
</table>
</td></tr>
</table>

Name	Description

Value	Description
	• 2048 • 4096
ECCValidCurves	An object containing a list of strings defining the valid elliptic curve algorithms for ECC templates. These may be specified using the well-known OIDs for ECC algorithms or by friendly name. Well-known OIDs include: • 1.2.840.10045.3.1.7 = P-256/prime256v1/secp256r1 • 1.3.132.0.34 = P-384/secp384r1 • 1.3.132.0.35 = P-521/secp521r1 When specifying by friendly name, do not include a slash (use "P-256", not "P-256/prime256v1/secp256r1").
AllowKeyReuse	A Boolean that indicates whether private key reuse is allowed (true) or not (false). This option allows to certificate renewals.
AllowWildcards	A Boolean that indicates whether wildcards are allowed (true) or not (false).
RFCEnforcement	A Boolean that indicates whether RFC 2818 compliance enforcement is enabled (true) or not (false). When this option is set to *true*, certificate enrollments made through Keyfactor Command for this template must include at least one DNS SAN. In the Keyfactor CommandManagement Portal, this causes the CN entered in PFX enrollment to automatically be replicated as a SAN, which the user can either change or accept. For CSR enrollment, if the CSR does not have a SAN that matches the CN, one will automatically be added to the certificate if this is set.

For example:

```
"TemplatePolicy": {
   "RSAValidKeySizes": [
      2048,
      4096
   ],
   "ECCValidCurves": [
      "1.2.840.10045.3.1.7",
      "1.3.132.0.34"
      "1.3.132.0.35"
   ],
   "AllowKeyReuse": false,
   "AllowWildcards": true,
   "RFCEnforcement": true,
```

Name	Description

	<pre>"AllowEd448": false,
	"AllowEd25519": false
	}</pre>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.14.2 GET Enrollment CSR Content My

The GET /Enrollment/CSR/Context/My method is used to check the templates and CAs available for CSR enrollment for the current user. This method has no input parameters. It returns HTTP 200 OK on a success with the list of templates that are available for enrollment via Keyfactor Command and the CAs those templates may be enrolled from along with template and CA configuration details. Results are returned based on the enrollment permissions of the user making the request—both Keyfactor Command permissions and template and CA level permissions on the originating CA. Templates or standalone CAs are included in the results only if the user has appropriate permissions in both locations and the template and CA are configured for CSR enrollment in Keyfactor Command.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateEnrollment: *EnrollCSR*

Table 322: GET Enrollment CSR Content My Response Body

Name	Description
Templates	An array containing the templates available for enrollment by the user. The array contains the following parameters:

Name	Description
Id	An integer indicating the Keyfactor Command reference ID of the certificate template.
Name	A string containing the common name (short name) of the template. This name typically does not contain spaces. For a template created using a Microsoft management tool, this will be the Microsoft template name.
DisplayName	A string containing the common name (short name) of the template. This name typically does not contain spaces. For a template created using a Microsoft management tool, this will be the Microsoft template name.
Forest	A string containing the name of the configuration tenant the template is associated with.
KeySize	A string indicating the minimum supported key size of the template.
RequiresApproval	A Boolean indicating whether the template has been configured with the Microsoft *CA certificate manager approval* option enabled (*true*) or not (*false*).
RFCEnforcement	A Boolean indicating whether certificate enrollments made through Keyfactor Command for this template must include at least one DNS SAN (*true*) or not (*false*). In the Keyfactor Command Management Portal, this causes the CN entered in PFX enrollment to automatically be replicated as a SAN, which the user can either change or accept. For CSR enrollment, if the CSR does not have a SAN that matches the CN, one will automatically be added to the certificate if this is set. By default, this is set to *false* at a system-wide level and may be overridden on a template-by-template basis.
CAs	An array of certificate authorities from which the template is available for enrollment, that are configured for enrollment in Keyfactor Command, and on which the requesting user has enrollment permissions. Information about the CA includes:

Name	Description
Name	The full name of the CA, made up of the DNS hostname of the certificate authority (e.g.

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>corpca01.keyexample.com) and the logical name (e.g. CorpIssuingCA1) for a full name similar to corpca01.keyexample.com\\CorpIssuingCA1.</td></tr>
<tr><td>RFCEnforcement</td><td>A Boolean that sets whether certificate enrollments made through Keyfactor Command for this CA must include at least one DNS SAN (true) or not (false). In the Keyfactor Command Management Portal, this causes the CN entered in PFX enrollment to automatically be replicated as a SAN, which the user can either change or accept. For CSR enrollment, if the CSR does not have a SAN that matches the CN, one will automatically be added to the certificate if this is set. This setting at the CA level applies only to standalone CAs. For CAs that use templates, this setting is controlled at the template level and is ignored at the CA level.</td></tr>
<tr><td>SubscriberTerms</td><td>A Boolean that sets whether to add a checkbox on the enrollment pages to force users to agree to a custom set of terms before enrolling (true) or not (false).

Tip: Configure a link to the custom terms using the URL to Subscriber Terms application setting. See Application Settings: Enrollment Tab on page 560 in the Keyfactor Command Reference Guide for more information.</td></tr>
</table>
</td></tr>
<tr><td>EnrollmentFields</td><td>An object containing custom enrollment fields. These are configured on a per-template basis to allow you to submit custom fields with CSR enrollments and PFX enrollments to supply custom request attributes to the CA during the enrollment process. This functionality offers such benefits as:
• Preventing users from requesting invalid certificates, based on your specific certificate requirements per template.
• Providing additional information to the CA with the CSR.

Once created on the template, these values are shown in Keyfactor Command on the PFX and CSR enrollment pages in the Additional Enrollment Fields section. The</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
fields are mandatory during enrollment. The data will appear on the CA / Issued Certificates attribute tab for certificates enrolled with a template configured with Keyfactor Command enrollment fields.

Note: These are not metadata fields, so they are not stored in the Keyfactor Command database, but simply passed through to the CA. The CA in turn could, via a gateway or policy module, use this data to perform required actions.

The array contains the following parameters:

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the ID of the custom enrollment field.</td></tr>
<tr><td>Name</td><td>A string indicating the name of the custom enrollment field. This name will appear on the enrollment pages.</td></tr>
<tr><td>Options</td><td>For multiple choice values, an array of strings containing the value choices.</td></tr>
<tr><td>DataType</td><td>An integer indicating the parameter type. The options are:

<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>1</td><td>String: A free-form data entry field.</td></tr>
<tr><td>2</td><td>Multiple Choice: Provides a list of acceptable values for the field. The multiple choice values are provided in the Options parameter.</td></tr>
</table>
</td></tr>
</table>
For example:

<pre>
"EnrollmentFields": [
   {
      "Id": 3,
      "Name": "MyCustomField",
      "Options": ["Green","Red","Yellow","Blue"],
      "DataType": 2
   }
</pre>
</td></tr>
</table>
</td></tr>
</table>

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td>]</td></tr><tr><td>MetadataFields</td><td>An object containing template-level metadata field settings. Template-level metadata field configurations can override global metadata field configurations in these possible ways: - Configuration on the metadata field of *required*, *optional* or *hidden*. - The *default value* for the metadata field. - A *regular expression* defined for the field (string fields only) against which entered data will be validated along with its associated message. - For fields of data type *multiple choice*, the list of values that appear in multiple choice dropdowns. Metadata field settings defined on a template apply to enrollments made with that template only. Template-level metadata field settings, if defined, take precedence over global-level metadata field settings. The metadata field settings array contains the following parameters:<table><tr><th>Name</th><th>Description</th></tr><tr><td>Id</td><td>The Keyfactor Command reference ID of the template-specific metadata setting.</td></tr><tr><td>DefaultValue</td><td>A string containing the default value defined for the metadata field for the specific template.</td></tr><tr><td>MetadataId</td><td>An integer indicating the global metadata field associated with the template-specific settings.</td></tr><tr><td>Validation</td><td>A string containing the template-specific regular expression against which data entered in a string field will be validated. When a user enters information in a metadata field that does not match the specified regular expression, he or she will see the warning message specified in the *Message* field. For example: <code>^[a-zA-Z0-9'_\.\-]*@(keyexample\.org|keyexample\.com)$</code> This regular expression specifies that the data entered in the field must consist of some number of characters prior</td></tr></table></td></tr></table>

3.2.14.3 GET Enrollment PFX Content My

The GET /Enrollment/PFX/Context/My method is used to check the templates and CAs available for PFX enrollment for the current user. This method has no input parameters. It returns HTTP 200 OK on a success with the list of templates that are available for enrollment via Keyfactor Command and the CAs those templates may be enrolled from along with template and CA configuration details. Results are returned based on the enrollment permissions of the user making the request—both Keyfactor Command permissions and template and CA level permissions on the originating CA. Templates or standalone CAs are included in the results only if the user has appropriate permissions in both locations and the template and CA are configured for PFX enrollment in Keyfactor Command.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateEnrollment: *EnrollPFX*

Table 323: GET Enrollment PFX Content My Response Body

Name	Description
Templates	An array containing the templates available for enrollment by the user. The array contains the following parameters: **Name** / **Description** Id — An integer indicating the Keyfactor Command reference ID of the certificate template. Name — A string containing the common name (short name) of the template. This name typically does not contain spaces. For a template created using a Microsoft management tool, this will be the Microsoft template name. DisplayName — A string containing the common name (short name) of the template. This name typically does not contain spaces. For a template created using a Microsoft management tool, this will be the Microsoft template name. Forest — A string containing the name of the configuration tenant the template is associated with. KeySize — A string indicating the minimum supported key size of the template. RequiresApproval — A Boolean indicating whether the template has been configured with the Microsoft *CA certificate manager approval* option enabled (*true*) or not (*false*). RFCEnforcement — A Boolean indicating whether certificate enrollments made through Keyfactor Command for this template must include at least one DNS SAN (*true*) or not (*false*). In the Keyfactor Command Management Portal, this causes the CN entered in PFX enrollment to automatically be replicated as a SAN, which the user can either change or accept. For CSR enrollment, if the CSR does not have a SAN that matches the CN, one will automatically be added to the certificate if this is set. By default, this is set to *false* at a system-wide level and may be overridden on a template-by-template basis. CAs — An array of certificate authorities from which the template is available for enrollment, that are configured for enrollment in Keyfactor Command, and on which the requesting user has enrollment permissions. Information about the CA includes: **Name** / **Description** Name — The full name of the CA, made up of the DNS hostname of the certificate authority (e.g.

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>corpca01.keyexample.com) and the logical name (e.g. CorpIssuingCA1) for a full name similar to corpca01.keyexample.com\\CorpIssuingCA1.</td></tr>
<tr><td>RFCEnforcement</td><td>A Boolean that sets whether certificate enrollments made through Keyfactor Command for this CA must include at least one DNS SAN (true) or not (false). In the Keyfactor Command Management Portal, this causes the CN entered in PFX enrollment to automatically be replicated as a SAN, which the user can either change or accept. For CSR enrollment, if the CSR does not have a SAN that matches the CN, one will automatically be added to the certificate if this is set. This setting at the CA level applies only to standalone CAs. For CAs that use templates, this setting is controlled at the template level and is ignored at the CA level.</td></tr>
<tr><td>SubscriberTerms</td><td>A Boolean that sets whether to add a checkbox on the enrollment pages to force users to agree to a custom set of terms before enrolling (true) or not (false).

Tip: Configure a link to the custom terms using the URL to Subscriber Terms application setting. See <a>Application Settings: Enrollment Tab on page 560 in the Keyfactor Command Reference Guide for more information.</td></tr>
</table>
</td></tr>
<tr><td>Enroll-mentFields</td><td>An object containing custom enrollment fields. These are configured on a per-template basis to allow you to submit custom fields with CSR enrollments and PFX enrollments to supply custom request attributes to the CA during the enrollment process. This functionality offers such benefits as:
• Preventing users from requesting invalid certificates, based on your specific certificate requirements per template.
• Providing additional information to the CA with the CSR.

Once created on the template, these values are shown in Keyfactor Command on the PFX and CSR enrollment pages in the Additional Enrollment Fields section. The</td></tr>

<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
fields are mandatory during enrollment. The data will appear on the CA / Issued Certificates attribute tab for certificates enrolled with a template configured with Keyfactor Command enrollment fields.

Note: These are not metadata fields, so they are not stored in the Keyfactor Command database, but simply passed through to the CA. The CA in turn could, via a gateway or policy module, use this data to perform required actions.

The array contains the following parameters:

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the ID of the custom enrollment field.</td></tr>
<tr><td>Name</td><td>A string indicating the name of the custom enrollment field. This name will appear on the enrollment pages.</td></tr>
<tr><td>Options</td><td>For multiple choice values, an array of strings containing the value choices.</td></tr>
<tr><td>DataType</td><td>An integer indicating the parameter type. The options are:

<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>1</td><td>String: A free-form data entry field.</td></tr>
<tr><td>2</td><td>Multiple Choice: Provides a list of acceptable values for the field. The multiple choice values are provided in the Options parameter.</td></tr>
</table>
</td></tr>
</table>
For example:

<pre>
"EnrollmentFields": [
   {
      "Id": 3,
      "Name": "MyCustomField",
      "Options": ["Green","Red","Yellow","Blue"],
      "DataType": 2
   }
</pre>
</td></tr>
</table>
</td></tr>
</table>

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td>]</td></tr><tr><td>MetadataFields</td><td>An object containing template-level metadata field settings. Template-level metadata field configurations can override global metadata field configurations in these possible ways: - Configuration on the metadata field of *required*, *optional* or *hidden*. - The *default value* for the metadata field. - A *regular expression* defined for the field (string fields only) against which entered data will be validated along with its associated message. - For fields of data type *multiple choice*, the list of values that appear in multiple choice dropdowns. Metadata field settings defined on a template apply to enrollments made with that template only. Template-level metadata field settings, if defined, take precedence over global-level metadata field settings. The metadata field settings array contains the following parameters:<table><tr><th>Name</th><th>Description</th></tr><tr><td>Id</td><td>The Keyfactor Command reference ID of the template-specific metadata setting.</td></tr><tr><td>DefaultValue</td><td>A string containing the default value defined for the metadata field for the specific template.</td></tr><tr><td>MetadataId</td><td>An integer indicating the global metadata field associated with the template-specific settings.</td></tr><tr><td>Validation</td><td>A string containing the template-specific regular expression against which data entered in a string field will be validated. When a user enters information in a metadata field that does not match the specified regular expression, he or she will see the warning message specified in the *Message* field. For example: <code>^[a-zA-Z0-9'_\.\-]*@ (keyexample\.org|keyexample\.com)$</code> This regular expression specifies that the data entered in the field must consist of some number of characters prior</td></tr></table></td></tr></table>

3.2.14.4 GET Enrollment Available Renewal ID

The GET /Enrollment/AvailableRenewal/ID/{id} method is used to check a specific certificate by ID to determine which renewal types are supported, if any. This method or the GET /Enrollment/AvailableRenewal/Thumbprint method can be used before using the POST /Enrollment/Renew method to make a determination as to which fields need to be submitted, depending on whether one-click renewal is supported. This method returns HTTP 200 OK on a success with the supported renewal type.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
Certificates: *Read*

At either the global or collection level. See note under CollectionId, below.

Table 324: GET Enrollment Available Renewal ID {id} Input Parameters

Name	In	Description
id	Path	**Required**. An integer specifying the Keyfactor Command reference ID of the certificate on which to check the renewal status. Use the *GET /Certificates* method to determine the certificate ID. This information is also available in the certificate details for a certificate in the Keyfactor Command Management Portal.
CollectionId	Query	An integer specifying an optional certificate collection identifier to validate that the user executing the request has sufficient permissions to do so. If a certificate collection ID is not supplied, the user must have global permissions to complete the action. Supplying a certificate collection ID allows for a check of the user's certificate collection-level permissions to determine whether the user has sufficient permissions at a collection level to complete the action. See Certificate Permissions on page 588 in the *Keyfactor Command Reference Guide* for more information.

Table 325: GET Enrollment Available Renewal ID {id} Response Body

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>AvailableRenewalType</td><td>An integer indicating the supported renewal type. Possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>0</td><td>None—renewal is not supported for this certificate.</td></tr>
<tr><td>1</td><td>Seeded PFX is supported. A renewal can be done if a template and certificate authority are supplied in the renewal request, but one-click renewal is not supported.</td></tr>
<tr><td>2</td><td>One-click renewal is supported. A renewal can be done using the same template and certificate authority used in the original certificate, and a template and certificate authority do not need to be supplied in the renewal request.
One-click renewal is only supported if either one of the following is true:
The certificate is located together with its private key in one or more managed certificate store(s).
The certificate was enrolled with a template that has been configured in Keyfactor Command to allow private keys to be encrypted and stored in the Keyfactor Command database. See Certificate Templates on page 333 in the Keyfactor Command Reference Guide for more information.</td></tr>
</table>
Tip: If the AvailableRenewalType is 2, 1 is also supported for the certificate.</td></tr>
<tr><td>Message</td><td>A message providing more details about the available renewal type result (e.g. "One click renewal is not available for this certificate. Template does not have PFX enrollment enabled.").</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.14.5 GET Enrollment Available Renewal Thumbprint

The GET /Enrollment/AvailableRenewal/Thumbprint/{thumbprint} method is used to check a specific certificate by thumbprint to determine which renewal types are supported, if any. This method or the GET /Enrollment/AvailableRenewal/ID method can be used before using the POST /Enrollment/Renew method to make a determination as to which fields need to be submitted, depending on whether one-click renewal is supported. This method returns HTTP 200 OK on a success with the supported renewal type.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
Certificates: *Read*

At either the global or collection level. See note under CollectionId, below.

Table 326: GET Enrollment Available Renewal Thumbprint {thumbprint} Input Parameters

Name	In	Description
thumbprint	Path	**Required**. The thumbprint of the certificate on which to check the renewal status. Use the *GET /Certificates* method to determine the certificate thumbprint. This information is also available in the certificate details for a certificate in the Keyfactor Command Management Portal.
CollectionId	Query	An integer specifying an optional certificate collection identifier to validate that the user executing the request has sufficient permissions to do so. If a certificate collection ID is not supplied, the user must have global permissions to complete the action. Supplying a certificate collection ID allows for a check of the user's certificate collection-level permissions to determine whether the user has sufficient permissions at a collection level to complete the action. See Certificate Permissions on page 588 in the *Keyfactor Command Reference Guide* for more information.

Table 327: GET Enrollment Available Renewal Thumbprint {thumbprint} Response Body

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>AvailableRenewalType</td><td>An integer indicating the supported renewal type. Possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>0</td><td>None—renewal is not supported for this certificate.</td></tr>
<tr><td>1</td><td>Seeded PFX is supported. A renewal can be done if a template and certificate authority are supplied in the renewal request, but one-click renewal is not supported.</td></tr>
<tr><td>2</td><td>One-click renewal is supported. A renewal can be done using the same template and certificate authority used in the original certificate, and a template and certificate authority do not need to be supplied in the renewal request.
One-click renewal is only supported if either one of the following is true:
The certificate is located together with its private key in one or more managed certificate store(s).
The certificate was enrolled with a template that has been configured in Keyfactor Command to allow private keys to be encrypted and stored in the Keyfactor Command database. See Certificate Templates on page 333 in the Keyfactor Command Reference Guide for more information.</td></tr>
</table>
Tip: If the AvailableRenewalType is 2, 1 is also supported for the certificate.</td></tr>
<tr><td>Message</td><td>A message providing more details about the available renewal type result (e.g. "One click renewal is not available for this certificate. Template does not have PFX enrollment enabled.").</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.14.6 POST Enrollment CSR

The POST /Enrollment/CSR method is used to enroll for a certificate using a certificate signing request (CSR). This method returns HTTP 200 OK on a success with a message body containing a list of certificate details and any metadata that was associated with the certificate request.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: CertificateEnrollment: *EnrollCSR*

Tip: Use the GET /Enrollment/CSR/Context/My method before this method to check which templates and CAs are available for enrollment for the requesting user before submitting the enrollment request.

Note: As of Keyfactor Command version 10, enrollment (PFX and CSR), renewal, and revocation requests all flow through Keyfactor Command workflow. This will result in no changes to the enrollment, renewal, and revocation user experience unless customizations have been added in workflow (see Workflow Definitions on page 206).

Table 328: POST Enrollment CSR Input Parameters

Name	In	Description
CSR	Body	**Required**. The base-64 encoded CSR that will be passed in for enrollment.
PrivateKey	Body	A string containing the base-64 encoded private key that corresponds to the CSR to be saved with the enrollment. This is done to support private key retention in Keyfactor Command for requests made through CSR enrollment. The key should be provided in unencrypted PKCS#8 format. The private key option is only supported for enrollments done using templates configured in Keyfactor Command for private key retention.
Timestamp	Body	**Required**. The current date and time. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).
Template	Body	**Required***. A string that sets the name of the certificate template that should be used to issue the certificate. The template short name should be used. This field is **required** unless the enrollment is being done against a standalone CA.
CertificateAuthority	Body	**Required***. A string that sets the name of the certificate authority that will be used to enroll against if there is more than one available with the provided template name. The certificate authority name can either be provided in *hostname**logical name* format or as just the *logical name*. For example: corpca01.keyexample.com\\CorpIssuingCA1 **OR** CorpIssuingCA1 If no certificate authority is provided, one will be chosen at random from the certificate authorities available for enrollment with the provided *Template*. This field is optional unless the enrollment is being done against a standalone CA, in which case it is **required**.
IncludeChain	Body	A Boolean that sets whether to include the certificate chain in the response (true) or not (false). The default is *false*.
Metadata	Body	An array of key/value pairs that set the values for the metadata fields that will be associated with the certificate once it is in Keyfactor Command. The *key* is the field name and the *value* is the value for the field. For example: `"Metadata": {`

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>

```
   "AppOwnerFirstName": "William",  // This is a String
field.
   "AppOwnerLastName": "Smith",
   "AppOwnerEmailAddress": "willi-
am.smith@keyexample.com",
   "BusinessCritical": "true",      // This is a
Boolean field.
   "BusinessUnit": "E-Business",    // This is a
Multiple Choice field with a pre-defined value.
   "Notes": "Here are some notes.", // This is a
BigText field.
   "SiteCode": 3,                   // This is an
integer field.
   "TicketResolutionDate": "2021-07-23"   // This is a
Date field in yyyy-mm-dd format.
}
```

See Certificate Metadata on page 612 in the *Keyfactor Command Reference Guide* for more information.
</td></tr>
<tr><td>SANs</td><td>Body</td><td>An array of key/value pairs that represent the elements for Keyfactor Command to use when generating the subject alternative name (SAN) for the certificate requested by the CSR. Possible values for the key are:

<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>rfc822</td><td>RFC 822 Name</td></tr>
<tr><td>dns</td><td>DNS Name</td></tr>
<tr><td>directory</td><td>Directory Name</td></tr>
<tr><td>uri</td><td>Uniform Resource Identifier</td></tr>
<tr><td>ip4</td><td>IP v4 Address</td></tr>
<tr><td>ip6</td><td>IP v6 Address</td></tr>
<tr><td>registeredid</td><td>Registered ID (an OID)</td></tr>
<tr><td>ms_ntprincipalname</td><td>MS_NTPrincipalName (a string)</td></tr>
<tr><td>ms_ntdsreplication</td><td>MS_NTDSReplication (a GUID)</td></tr>
</table>

For example:</td></tr>
</table>

Name	In	Description

		<pre>"SANs": {
		  "dns": [
		  "dnssan1.keyexample.com",
		  "dnssan2.keyexample.com",
		  "dnssan3.keyexample.com"
		  ],
		  "ip4": [
		  "192.168.2.73"
		  ]
		}</pre>
		Note: Entering SANs with this option may either append or overwrite the SANs in the CSR request depending on how the issuing CA is configured. Please be sure to check that the certificate has the correct SANs after issuance. Any SAN added automatically as a result of the RFC 2818 compliance settings (see GET Templates on page 1922) will still be added alongside anything you add here. Review the SAN Attribute Policy Handler for the Keyfactor CA Policy Module (see Installing the Keyfactor CA Policy Module Handlers on page 2321 in the *Keyfactor Command Server Installation Guide*) for more information.

AdditionalEnrollmentFields	Body	An array of key/value pairs that provide values for any custom enrollment fields set on the certificate template to supply custom request attributes to the CA during the enrollment process. For example: `"AdditionalEnrollmentFields": { "CustomStringOne": "ValueOne", "CustomMultiChoiceTwo": "ValueTwo" }` See Certificate Template Operations on page 334 of the *Keyfactor Command Reference Guide* for more information.
x-CertificateFormat	Header	**Required**. The desired output format for the certificate. Available options are DER and PEM.

Table 329: POST Enrollment CSR Response Data

<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>CertificateInformation</td><td>Information about the certificate that was requested. CSR information includes:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>SerialNumber</td><td>A string indicating the serial number of the certificate.</td></tr>
<tr><td>IssuerDN</td><td>A string indicating the issuer DN of the certificate.</td></tr>
<tr><td>Thumbprint</td><td>A string indicating the thumbprint of the certificate.</td></tr>
<tr><td>KeyfactorID</td><td>An integer indicating the Keyfactor Command reference ID of the issued certificate.</td></tr>
<tr><td>Certificates</td><td>An array of certificates in the order of:
end entity
intermediate CA
Root CA
Intermediate CA and root CA certificates will only be included if the request parameter IncludeChain was set to true.</td></tr>
<tr><td>WorkflowInstanceId</td><td>A string containing the Keyfactor Command reference GUID of the workflow instance.

Tip: Both the WorkflowInstanceId and the WorkflowReferenceId refer to the same workflow instance record—one using a GUID and one using a more human readable integer.</td></tr>
<tr><td>WorkflowReferenceId</td><td>An integer containing the Keyfactor Command reference ID of the workflow instance.

Tip: Both the WorkflowInstanceId and the WorkflowReferenceId refer to the same workflow instance record—one using a GUID and one using a more human readable integer.</td></tr>
<tr><td>KeyfactorRequestId</td><td>An integer indicating the Keyfactor Command reference ID of the request.</td></tr>
</table></td></tr>
</table>

<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>RequestDisposition</td><td>A string indicating the state of the request (e.g. ISSUED).</td></tr>
<tr><td>DispositionMessage</td><td>A string providing a message regarding the enrollment (e.g. The private key was successfully retained.).</td></tr>
<tr><td>EnrollmentContext</td><td>An internally used Keyfactor Command field.</td></tr>
</table>
</td></tr>
<tr><td>Metadata</td><td>An array of the custom metadata values set on the certificate. The values vary depending on customization done in your environment. The information is presented in the following structure:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>MetadataFieldTypeName</td><td>A string containing the name of the metadata field in Keyfactor Command.</td></tr>
<tr><td>Value</td><td>The value of the metadata.</td></tr>
</table>
See Certificate Metadata on page 612 in the Keyfactor Command Reference Guide for more information.</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.14.7 POST Enrollment PFX

The POST /Enrollment/PFX method is used to enroll for a certificate by supplying data in the desired fields. This method returns HTTP 200 OK on a success with a message body containing a list of certificate details and any metadata that was associated with the certificate request.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: CertificateEnrollment: *EnrollPFX*

Global or container-level schedule permissions for certificate stores are needed to install a certificate generated with this method into a certificate store (see the x-CertificateFormat on page 1343 parameter) using the POST /Enrollment/PFX/Deploy method (see POST Enrollment PFX Deploy on page 1347) or POST /Enrollment/PFX/Replace method (see POST Enrollment PFX Replace on page 1352).

Tip: Use the GET /Enrollment/PFX/Context/My method before this method to check which templates and CAs are available for enrollment for the requesting user before submitting the enrollment request.

Note: As of Keyfactor Command version 10, enrollment (PFX and CSR), renewal, and revocation requests all flow through Keyfactor Command workflow. This will result in no changes to the enrollment, renewal, and revocation user experience unless customizations have been added in workflow (see Workflow Definitions on page 206).

This method has two available versions. Keyfactor recommends using the newer method when possible. For more information about versioning, see Versioning on page 721.

Version 2

Version 2 of the POST /Enrollment/PFX method redesigns how enrollment flow works to handle require approval functionality in a Keyfactor Command workflow with support for delivery into certificate stores. Users who are planning to use require approval workflow functionality *and* deliver enrolled certificates into certificate stores must use version 2 of this endpoint.

Note: The *PopulateMissingValuesFromAD* parameter has been removed from the version 2 endpoint.

Table 330: POST Enrollment PFX v2 Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>Stores</td><td>Body</td><td>An object containing a comma delimited set of arrays indicating the certificate stores to which the certificate should be distributed. Store details include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>StoreId</td><td>An array of GUIDs indicating the certificate store(s) to which the certificate should be deployed.
Use the GET /CertificateStores method (see <a>GET Certificate Stores on page 1100) with a query of "Approved -eq true" to retrieve a list of all your approved certificate stores to determine the GUID(s) of the store(s).</td></tr>
<tr><td>Alias</td><td>A string containing the alias of the certificate upon entry into the store. The format of and requirement for this varies depending on the certificate store type and whether the Overwrite flag is selected. See <a>PFX Enrollment on page 132 in the Keyfactor Command Reference Guide for more information.</td></tr>
<tr><td>Overwrite</td><td>A Boolean that sets whether a certificate in the store with the Alias provided should be overwritten with the new certificate (true) or not (false). The default is false.
Use the GET /Certificates/Locations/{id} method (see <a>GET Certificates Locations ID on page 940) to retrieve a list of the locations an existing certificate is in to determine the alias used for the certificate in the certificate store.</td></tr>
<tr><td>Properties</td><td>An array of key/value pairs for the unique parameters defined for the certificate store type that need to be populated for the certificate. The key is the name of the specific parameter from the certificate store type definition as returned in the JobProperties on the store type using the GET CertificateStoreTypes method and the value is the value that should be set for that parameter on the certificate in the certificate store. For example, for NetScaler, the key name that is optionally used to associate the certificate with a virtual server is NetscalerVserver and is returned by GET CertificateStoreTypes like so:
<code>"JobProperties": ["NetscalerVserver"]</code></td></tr>
</table>
</td></tr>
</table>

Name	In	Description
		Name / **Description** It can be seen in the Keyfactor Command Management Portal when editing the certificate store type in the field for *Management Job Custom Fields*. The setting is referenced using the following format: `"Properties": {"NetscalerVserver":"MyVirtualServerName"}` **Note:** The only built-in certificate store type that makes use of properties that can be set on a certificate-by-certificate basis in the store is NetScaler. You may have custom certificate store types that make use of this functionality.
CustomFriendlyName	Body	**Required***. A string that sets a custom friendly name for the certificate. This field is **required** if the *Require Custom Friendly Name* application setting is set to *true* (the default is *false*). See Application Settings: Enrollment Tab on page 560 in the *Keyfactor Command Reference Guide* for more information.
Password	Body	**Required**. A string that sets the password used to encrypt the contents of the PFX file. The minimum password length is controlled by the *Password Length* application setting. The default is *12*. See Application Settings: Enrollment Tab on page 560 in the *Keyfactor Command Reference Guide* for more information.
Subject	Body	**Required***. A string containing the subject name using X.500 format. For example: `"Subject": "CN=websrvr14.keyexample.com,OU=IT,O=\"Key Example, Inc.\",L=Independence,ST=OH,C=US"` This field is **required** if the *Common Name Regular Expression* application setting is set to the default value of *.+*. See Application Settings: Enrollment Tab on page 560 in the *Keyfactor Command Reference Guide* for more information.
IncludeChain	Body	A Boolean that sets whether to include the certificate chain in the response (true) or not (false). The default is *true*.
RenewalCertificateId	Body	An integer that sets the ID of the certificate to be renewed when the method is called on a certificate renewal. The *RenewalCertificateId* parameter is used in conjunction with *InstallIn-*

Name	In	Description
		toExistingCertificateStores parameter to make the determination as to distribution of the certificate to certificate stores. If *InstallIn-toExistingCertificateStores* is *true*, the certificate will be distributed to certificate stores that the certificate identified in *RenewalCertificateId* is found in.
CertificateAuthority	Body	**Required***. A string that sets the name of the certificate authority that will be used to enroll against if there is more than one available with the provided template name. The certificate authority name can either be provided in *hostname**logical name* format or as just the *logical name*. For example: corpca01.keyexample.com\\CorpIssuingCA1 **OR** CorpIssuingCA1 If no certificate authority is provided, one will be chosen at random from the certificate authorities available for enrollment with the provided *Template*. This field is optional unless the enrollment is being done against a standalone CA, in which case it is **required**.
Metadata	Body	An array of key/value pairs that set the values for the metadata fields that will be associated with the certificate once it is in Keyfactor Command. The *key* is the field name and the *value* is the value for the field. For example: `"Metadata": { "AppOwnerFirstName": "William", // This is a String field. "AppOwnerLastName": "Smith", "AppOwnerEmailAddress": "william.smith@keyexample.com", "BusinessCritical": "true", // This is a Boolean field. "BusinessUnit": "E-Business", // This is a Multiple Choice field with a pre-defined value. "Notes": "Here are some notes.", // This is a BigText field. "SiteCode": 3, // This is an integer field. "TicketResolutionDate": "2021-07-23" // This is a Date field in yyyy-mm-dd format. }` See Certificate Metadata on page 612 in the *Keyfactor Command Reference Guide* for more information.
Timestamp	Body	The current date and time. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>Template</td><td>Body</td><td>Required*. A string that sets the name of the certificate template that should be used to issue the certificate. The template short name should be used.
This field is required unless the enrollment is being done against a standalone CA.</td></tr>
<tr><td>SANs</td><td>Body</td><td>An array of key/value pairs that represent the elements for Keyfactor Command to use when generating the subject alternative name (SAN) for the certificate requested by the CSR. Possible values for the key are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>rfc822</td><td>RFC 822 Name</td></tr>
<tr><td>dns</td><td>DNS Name</td></tr>
<tr><td>directory</td><td>Directory Name</td></tr>
<tr><td>uri</td><td>Uniform Resource Identifier</td></tr>
<tr><td>ip4</td><td>IP v4 Address</td></tr>
<tr><td>ip6</td><td>IP v6 Address</td></tr>
<tr><td>registeredid</td><td>Registered ID (an OID)</td></tr>
<tr><td>ms_ntprincipalname</td><td>MS_NTPrincipalName (a string)</td></tr>
<tr><td>ms_ntdsreplication</td><td>MS_NTDSReplication (a GUID)</td></tr>
</table>
For example:
<pre>
"SANs": {
   "dns": [
      "dnssan1.keyexample.com",
      "dnssan2.keyexample.com",
      "dnssan3.keyexample.com"
   ],
   "ip4": [
      "192.168.2.73"
   ]
}
</pre></td></tr>
<tr><td>InstallIn-toExistingCertificateStores</td><td>Body</td><td>A Boolean that sets whether to deploy the certificate to certificate stores (true) or not (false). The default is true.
The RenewalCertificateId parameter is used in conjunction with InstallIn-</td></tr>
</table>

Name	In	Description
		toExistingCertificateStores parameter to make the determination as to distribution of the certificate to certificate stores. If *InstallIn-toExistingCertificateStores* is *true*, the certificate will be distributed to certificate stores that the certificate identified in *RenewalCertificateId* is found in.
AdditionalEnrollmentFields	Body	An array of key/value pairs that provide values for any custom enrollment fields set on the certificate template to supply custom request attributes to the CA during the enrollment process. For example: `"AdditionalEnrollmentFields": { "CustomStringOne": "MyValue", "CustomMultiChoiceOne": "ValueTwo" }` See Certificate Template Operations on page 334 in the *Keyfactor Command Reference Guide* for more information.
x-CertificateFormat	Header	**Required**. The desired output format for the certificate. Available options are PFX, Zip, and Store. If Store is selected, no certificate blob will be returned in the response. The Store option is designed to be used when pushing a newly obtained PFX certificate to a certificate store (see POST Enrollment PFX Deploy on page 1347).

Table 331: POST Enrollment PFX v2 Response Data

<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>SuccessfulStores</td><td>An object containing a comma delimited list of certificate stores, referenced by certificate store GUID, to which the certificate was successfully scheduled for deployment.</td></tr>
<tr><td>CertificateInformation</td><td>Information about the certificate that was requested. Certificate information includes:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>SerialNumber</td><td>A string indicating the serial number of the certificate.</td></tr>
<tr><td>IssuerDN</td><td>A string indicating the issuer DN of the certificate.</td></tr>
<tr><td>Thumbprint</td><td>A string indicating the thumbprint of the certificate.</td></tr>
<tr><td>KeyfactorID</td><td>An integer indicating the Keyfactor Command reference ID of the issued certificate.</td></tr>
<tr><td>PKCS12Blob</td><td>A string containing the base-64-encoded representation of the certificate in Zip or PFX format with the optional certificate chain. The string will need to be base-64 decoded for both Zip and PFX. This can be accomplished in a number of ways. For example, using PowerShell:
<pre>$b64 = Get-Content 'C:\path\to\source\file'
$targetFile = 'C:\path\to\target\file'

$bytes = [Convert]::FromBase64String($b64)
[IO.File]::WriteAllBytes($targetFile, $bytes)</pre>
Note: No value is returned for the PKCS12Blob if you select a certificate format of Store in the header. The Store option is designed to be used when pushing a newly obtained PFX certificate to a certificate store (see POST Enrollment PFX Deploy on page 1347).</td></tr>
<tr><td>Password</td><td>An internally used Keyfactor Command field.</td></tr>
<tr><td>WorkflowInstanceId</td><td>A string containing the Keyfactor Command reference GUID of the workflow instance.

Tip: Both the WorkflowInstanceId and the WorkflowReferenceId refer to the same workflow</td></tr>
</table></td></tr>
</table>

<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>instance record—one using a GUID and one using a more human readable integer.</td></tr>
<tr><td>WorkflowReferenceId</td><td>An integer containing the Keyfactor Command reference ID of the workflow instance.

Tip: Both the WorkflowInstanceId and the WorkflowReferenceId refer to the same workflow instance record—one using a GUID and one using a more human readable integer.</td></tr>
<tr><td>KeyfactorRequestId</td><td>An integer indicating the Keyfactor Command reference ID of the request.</td></tr>
<tr><td>RequestDisposition</td><td>A string indicating the state of the request (e.g. ISSUED).</td></tr>
<tr><td>DispositionMessage</td><td>A string providing a message regarding the enrollment (e.g. The private key was successfully retained.).</td></tr>
<tr><td>EnrollmentContext</td><td>An internally used Keyfactor Command field.</td></tr>
</table>
</td></tr>
<tr><td>Metadata</td><td>An array of the custom metadata values set on the certificate. The values vary depending on customization done in your environment. The information is presented in the following structure:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>MetadataFieldTypeName</td><td>A string containing the name of the metadata field in Keyfactor Command.</td></tr>
<tr><td>Value</td><td>The value of the metadata.</td></tr>
</table>
See Certificate Metadata on page 612 in the Keyfactor Command Reference Guide for more information.</td></tr>
</table>

Version 1

Version 1 of the POST /Enrollment/PFX method includes the same capabilities as version 2 except when used in conjunction with Keyfactor Command workflows that require approval with an intended end goal of delivering the resulting certificate into a certificate store. In this specific case, version 2 must be used.

Table 332: POST Enrollment PFX v1 Input Parameters

Name	In	Description
CustomFriendlyName	Body	**Required***. A string that sets a custom friendly name for the certificate. This field is **required** if the *Require Custom Friendly Name* application setting is set to *true* (the default is *false*). See Application Settings: Enrollment Tab on page 560 in the *Keyfactor Command Reference Guide* for more information.
Password	Body	**Required**. A string that sets the password used to encrypt the contents of the PFX file. The minimum password length is controlled by the *Password Length* application setting. The default is *12*. See Application Settings: Enrollment Tab on page 560 in the *Keyfactor Command Reference Guide* for more information.
PopulateMissingValuesFromAD	Body	A Boolean that sets whether to populate the information in the subject from Active Directory (true) or not (false). The default is *false*.
Subject	Body	**Required***. A string containing the subject name using X.500 format. For example: `"Subject": "CN=webservr14.keyexample.com,OU=IT,O=\"Key Example, Inc.\",L=Independence,ST=OH,C=US"` This field is **required** if the *Common Name Regular Expression* application setting is set to the default value of *.+*. See Application Settings: Enrollment Tab on page 560 in the *Keyfactor Command Reference Guide* for more information.
IncludeChain	Body	A Boolean that sets whether to include the certificate chain in the response (true) or not (false). The default is *true*.
RenewalCertificateId	Body	An integer that sets the ID of the certificate to be renewed when the method is called on a certificate renewal.
CertificateAuthority	Body	**Required***. A string that sets the name of the certificate authority that will be used to enroll against if there is more than one available with the provided template name. The certificate authority name can either be provided in *hostname**logical name* format or as just the *logical name*. For example: `corpca01.keyexample.com\\CorpIssuingCA1` **OR** `CorpIssuingCA1` If no certificate authority is provided, one will be chosen at random from the certificate authorities available for enrollment with the provided *Template*.

Name	In	Description
		This field is optional unless the enrollment is being done against a standalone CA, in which case it is **required**.
Timestamp	Body	The current date and time. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).
Template	Body	**Required*** . A string that sets the name of the certificate template that should be used to issue the certificate. The template short name should be used. This field is **required** unless the enrollment is being done against a standalone CA.

Metadata	Body	An array of key/value pairs that set the values for the metadata fields that will be associated with the certificate once it is in Keyfactor Command. The *key* is the field name and the *value* is the value for the field. For example:
		`"Metadata": {`
		`"AppOwnerFirstName": "William", // This is a String field.`
		`"AppOwnerLastName": "Smith",`
		`"AppOwnerEmailAddress": "william.smith@keyexample.com",`
		`"BusinessCritical": "true", // This is a Boolean field.`
		`"BusinessUnit": "E-Business", // This is a Multiple Choice field with a pre-defined value.`
		`"Notes": "Here are some notes.", // This is a BigText field.`
		`"SiteCode": 3, // This is an integer field.`
		`"TicketResolutionDate": "2021-07-23" // This is a Date field in yyyy-mm-dd format.`
		`}`
		See Certificate Metadata on page 612 in the *Keyfactor Command Reference Guide* for more information.

SANs	Body	An array of key/value pairs that represent the elements for Keyfactor Command to use when generating the subject alternative name (SAN) for the certificate requested by the CSR. Possible values for the key are:

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>rfc822</td><td>RFC 822 Name</td></tr>
<tr><td>dns</td><td>DNS Name</td></tr>
<tr><td>directory</td><td>Directory Name</td></tr>
<tr><td>uri</td><td>Uniform Resource Identifier</td></tr>
<tr><td>ip4</td><td>IP v4 Address</td></tr>
<tr><td>ip6</td><td>IP v6 Address</td></tr>
<tr><td>registeredid</td><td>Registered ID (an OID)</td></tr>
<tr><td>ms_ntprincipalname</td><td>MS_NTPrincipalName (a string)</td></tr>
<tr><td>ms_ntdsreplication</td><td>MS_NTDSReplication (a GUID)</td></tr>
</table>
For example:
<pre>"SANs": {
   "dns": [
      "dnssan1.keyexample.com",
      "dnssan2.keyexample.com",
      "dnssan3.keyexample.com"
   ],
   "ip4": [
      "192.168.2.73"
   ]
}</pre>
</td></tr>
<tr><td>AdditionalEnrollmentFields</td><td>Body</td><td>An array of key/value pairs that provide values for any custom enrollment fields set on the certificate template to supply custom request attributes to the CA during the enrollment process. For example:
<code>"AdditionalEnrollmentFields": { "CustomStringOne": "MyValue", "CustomMultiChoiceOne": "ValueTwo" }</code>
See <a>Certificate Template Operations on page 334 in the Keyfactor Command Reference Guide for more information.</td></tr>
<tr><td>x-CertificateFormat</td><td>Header</td><td>Required. The desired output format for the certificate. Available options are PFX, Zip, and Store. If Store is selected, no certificate blob will be returned in the response. The Store option is designed to be used when pushing a newly obtained PFX certificate to a certificate store (see <a>POST Enrollment PFX Deploy on page 1347).</td></tr>
</table>

Table 333: POST Enrollment PFX v1 Response Data

<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>CertificateInformation</td><td>Information about the certificate that was requested. Certificate information includes:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>SerialNumber</td><td>A string indicating the serial number of the certificate.</td></tr>
<tr><td>IssuerDN</td><td>A string indicating the issuer DN of the certificate.</td></tr>
<tr><td>Thumbprint</td><td>A string indicating the thumbprint of the certificate.</td></tr>
<tr><td>KeyfactorID</td><td>An integer indicating the Keyfactor Command reference ID of the issued certificate.</td></tr>
<tr><td>PKCS12Blob</td><td>A string containing the base-64-encoded representation of the certificate in Zip or PFX format with the optional certificate chain. The string will need to be base-64 decoded for both Zip and PFX. This can be accomplished in a number of ways. For example, using PowerShell:
<pre>$b64 = Get-Content 'C:\path\to\source\file'
$targetFile = 'C:\path\to\target\file'

$bytes = [Convert]::FromBase64String($b64)
[IO.File]::WriteAllBytes($targetFile, $bytes)</pre>
Note: No value is returned for the PKCS12Blob if you select a certificate format of Store in the header. The Store option is designed to be used when pushing a newly obtained PFX certificate to a certificate store (see <a>POST Enrollment PFX Deploy on page 1347).</td></tr>
<tr><td>Password</td><td>An internally used Keyfactor Command field.</td></tr>
<tr><td>WorkflowInstanceId</td><td>A string containing the Keyfactor Command reference GUID of the workflow instance.

Tip: Both the WorkflowInstanceId and the WorkflowReferenceId refer to the same workflow instance record—one using a GUID and one using a more human readable integer.</td></tr>
</table></td></tr>
</table>

<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>WorkflowReferenceId</td><td>An integer containing the Keyfactor Command reference ID of the workflow instance.

Tip: Both the WorkflowInstanceId and the WorkflowReferenceId refer to the same workflow instance record—one using a GUID and one using a more human readable integer.</td></tr>
<tr><td>KeyfactorRequestId</td><td>An integer indicating the Keyfactor Command reference ID of the request.</td></tr>
<tr><td>RequestDisposition</td><td>A string indicating the state of the request (e.g. ISSUED).</td></tr>
<tr><td>DispositionMessage</td><td>A string providing a message regarding the enrollment (e.g. The private key was successfully retained.).</td></tr>
<tr><td>EnrollmentContext</td><td>An internally used Keyfactor Command field.</td></tr>
</table>
</td></tr>
<tr><td>Metadata</td><td>An array of the custom metadata values set on the certificate. The values vary depending on customization done in your environment. The information is presented in the following structure:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>MetadataFieldTypeName</td><td>A string containing the name of the metadata field in Keyfactor Command.</td></tr>
<tr><td>Value</td><td>The value of the metadata.</td></tr>
</table>
See Certificate Metadata on page 612 in the Keyfactor Command Reference Guide for more information.</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.14.8 POST Enrollment CSR Parse

The POST /Enrollment/CSR/Parse method takes a CSR in the body, parses it, and returns all elements that were found in the CSR. This method returns HTTP 200 OK on a success with the parsed CSR contents.

Table 334: POST Enrollment CSR Parse Input Parameters

Name	In	Description
CSR	Body	**Required**. Base-64-encoded CSR with the Begin and End Certificate Request tags.

Table 335: POST Enrollment CSR Parse Response Data

Name	Description
(CSR Contents)	An array containing key/value pairs representing all the elements in the CSR. Possible values include:

Name	Description
Key Length	An integer indicating the desired key size of the certificate.
Key Type	A string indicating the desired key encryption of the certificate.
CN	The common name of the certificate.
O	The organization of the certificate.
OU	The organizational unit of the certificate.
L	The city of the certificate.
ST	The state of the certificate.
C	The country (two characters) of the certificate.
E	The email address of the certificate.
DNS Name	A SAN value containing a DNS name.
IP Address	A SAN value containing an IP v4 or IP v6 address.
RFC822 Name	A SAN value containing an email message.
URL	A SAN value containing a uniform resource identifier.
Directory Name	A SAN value containing a directory name.
Registered ID	A SAN value containing a registered ID.
Other name:Principal Name	A SAN value containing a user principal name (UPN) value.
Other name:DS Object Guid	A SAN value containing the MS_NTDSReplication value.

Note: Some of these fields cannot be added to a CSR generated within Keyfactor Command (e.g. URL) and will only be found in CSRs generated outside Keyfactor Command.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.14.9 POST Enrollment PFX Deploy

The POST /Enrollment/PFX/Deploy method is used to put a certificate into a certificate store. It is intended to be used immediately after using the POST /Enrollment/PFX method to enroll for a PFX using the *Store* value for the *x-certificateformat* header (see POST Enrollment PFX on page 1332) or the POST /Enrollment/Renew method to renew a certificate already in a certificate store. This method returns HTTP 200 OK on a success with a message body containing the failed and succeeded stores.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateStoreManagement: *Schedule*
CertificateEnrollment: *EnrollPFX*

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Tip: The POST /Enrollment/PFX/Deploy method must be used within 5 minutes of acquiring a certificate with the POST /Enrollment/PFX or POST /Enrollment/Renew method as the same user who executed the certificate request. After 5 minutes, the temporary staging data needed in order to deploy the certificate is automatically cleared and is no longer available for deployment.

Table 336: POST Enrollment PFX Deploy Input Parameters

<table>
<tr><th>Name</th><th>Type</th><th>Description</th></tr>
<tr><td>Stores</td><td>Body</td><td>Required*. An array indicating the certificate stores to which the certificate should be deployed with additional properties as needed based on the store type and whether an existing certificate is being overwritten with the new certificate. Store parameters are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>StoreId</td><td>An array of GUIDs indicating the certificate store(s) to which the certificate should be deployed.
Use the GET /CertificateStores method (see GET Certificate Stores on page 1100) with a query of "Approved -eq true" to retrieve a list of all your approved certificate stores to determine the GUID(s) of the store(s).</td></tr>
<tr><td>Alias</td><td>The alias of the certificate upon entry into the store. The format of and requirement for this varies depending on the certificate store type and whether the Overwrite flag is selected. See PFX Enrollment on page 132 in the Keyfactor Command Reference Guide for more information.</td></tr>
<tr><td>Overwrite</td><td>A Boolean that sets whether a certificate in the store with the Alias provided should be overwritten with the new certificate (true) or not (false). The default is false.
Use the GET /Certificates/Locations/{id} method (see GET Certificates Locations ID on page 940) to retrieve a list of the locations an existing certificate is in to determine the alias used for the certificate in the certificate store.</td></tr>
<tr><td>Properties</td><td>An array of key/value pairs for the unique parameters defined for the certificate store type that need to be populated for the certificate. The key is the name of the specific parameter from the certificate store type definition as returned in the JobProperties on the store type using the GET CertificateStoreTypes method and the value is the value that should be set for that parameter on the certificate in the certificate store. For example, for NetScaler, the key name that is optionally used to associate the certificate with a virtual server is NetscalerVserver and is returned by GET CertificateStoreTypes like so:
<code>"JobProperties": ["NetscalerVserver"]</code>
It can be seen in the Keyfactor Command Management Portal when editing the certificate store type in the field for Management Job Custom Fields.</td></tr>
</table></td></tr>
</table>

<table>
<tr><th>Name</th><th>Type</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>The setting is referenced using the following format:
<pre>"Properties": {"Nets-calerVserver":"MyVirtualServerName"}</pre>
Note: The only built-in certificate store type that makes use of properties that can be set on a certificate-by-certificate basis in the store is NetScaler. You may have custom certificate store types that make use of this functionality.</td></tr>
</table>

This replaces the StoresIDs and StoreTypes parameters as of Keyfactor Command version 9.4.
</td></tr>
<tr><td>Password</td><td>Body</td><td>Required*. A string with a password used to secure the certificate in the certificate store. This field is required for store types that require an entry password, such as PEM stores.</td></tr>
<tr><td>CertificateId</td><td>Body</td><td>Required*. The integer for the certificate that needs to be deployed. This is returned in the response to the POST /Enrollment/PFX or POST /Enrollment/Renew request as the KeyfactorId.

Note: For enrollments that do not require manager approval (where the certificate is issued immediately), the CertificateId is required. The RequestId may be provided but is not required in this case. For enrollments that do require manager approval (where the certificate is not issued immediately), only the KeyfactorRequestId will be returned on the enrollment and the RequestId is required for deployment.</td></tr>
<tr><td>RequestId</td><td>Body</td><td>Required*. The integer of the request ID for the certificate that needs to be deployed. This is returned in the response to the POST /Enrollment/PFX or POST /Enrollment/Renew request as the KeyfactorRequestId.
See the note under CertificateId regarding when this field is required and when it is not.</td></tr>
<tr><td>JobTime</td><td>Body</td><td>The date and time when the certificate should be deployed. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z). Dates in the past will cause a management job to be created to run immediately. Dates in the future will result in a management job set to run in the future. The default is to create a management job that runs immediately.</td></tr>
<tr><td>StoreIds</td><td>Body</td><td>An array of the certificate store GUIDs for the stores to which the certificate should be added.</td></tr>
</table>

<table>
<tr><th>Name</th><th>Type</th><th>Description</th></tr>
<tr><td></td><td></td><td>The StoreIds parameter is obsolete as of Keyfactor Command version 9.4 and has been replaced by the Stores parameter. It is still supported for backward compatibility, but no longer required.</td></tr>
<tr><td>StoreTypes</td><td>Body</td><td>An array of store types used with additional properties as needed based on the store type and whether an existing certificate is being overwritten with the new certificate.
The StoreTypes parameter is obsolete as of Keyfactor Command version 9.4 and has been replaced by the Stores parameter. It is still supported for backward compatibility, but is no longer required.
Store type parameters are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>StoreTypeId</td><td>The type of certificate store the certificate is being deployed to.
The possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>0</td><td>Java Keystore</td></tr>
<tr><td>2</td><td>PEM File</td></tr>
<tr><td>3</td><td>F5 SSL Profiles</td></tr>
<tr><td>4</td><td>IIS Roots</td></tr>
<tr><td>5</td><td>NetScaler</td></tr>
<tr><td>6</td><td>IIS Personal</td></tr>
<tr><td>7</td><td>F5 Web Server</td></tr>
<tr><td>8</td><td>IIS Revoked</td></tr>
<tr><td>9</td><td>F5 Web Server REST</td></tr>
<tr><td>10</td><td>F5 SSL Profiles REST</td></tr>
<tr><td>11</td><td>F5 CA Bundles REST</td></tr>
<tr><td>100</td><td>Amazon Web Services</td></tr>
</table></td></tr>
</table></td></tr>
</table>

<table>
<tr><th>Name</th><th>Type</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>101</td><td>File Transfer Protocol</td></tr>
<tr><td>1xx</td><td>User-defined certificate stores will be given a type ID over 101.</td></tr>
</table>
</td></tr>
<tr><td>Alias</td><td>The alias of the certificate upon entry into the store. The format of and requirement for this varies depending on the certificate store type and whether the Overwrite flag is selected. See PFX Enrollment on page 132 in the Keyfactor Command Reference Guide for more information.</td></tr>
<tr><td>Overwrite</td><td>A Boolean that sets whether a certificate in the store with the Alias provided should be overwritten with the new certificate (true) or not (false). The default is false.
Use the GET /Certificates/Locations/{id} method (see GET Certificates Locations ID on page 940) to retrieve a list of the locations an existing certificate is in to determine the alias used for the certificate in the certificate store.</td></tr>
<tr><td>Properties</td><td>An array of key/value pairs for the unique parameters defined for the certificate store type that need to be populated for the certificate. The key is the name of the specific parameter from the certificate store type definition as returned in the JobProperties on the store type using the GET CertificateStoreTypes method and the value is the value that should be set for that parameter on the certificate in the certificate store. For example, for NetScaler, the key name that is optionally used to associate the certificate with a virtual server is NetscalerVserver and is returned by GET CertificateStoreTypes like so:
<pre>"JobProperties": ["NetscalerVserver"]</pre>It can be seen in the Keyfactor Command Management Portal when editing the certificate store type in the field for Management Job Custom Fields.
The setting is referenced using the following format:
<pre>"Properties": [{"NetscalerVserver":"MyVirtualServerName"}]</pre>Note: The only built-in certificate store type that</td></tr>
</table>
</td></tr>
</table>

Name	Type	Description
		Name / **Description** makes use of properties that can be set on a certificate-by-certificate basis in the store is NetScaler. You may have custom certificate store types that make use of this functionality.

Table 337: POST Enrollment PFX Deploy Response Data

Name	Description
SuccessfulStores	An array of GUIDs for the certificates stores for which management jobs to deploy the certificate were successfully created. **Note:** Successful creation of a management job to deploy a certificate to a certificate store does not necessarily mean that a certificate will successfully be deployed to the store. A management job may fail for any number of reasons (e.g. permissions on the store). Use the *GET /Certificates/{id}* method with *includeLocations=true* to confirm that the certificate has successfully been deployed to the target store(s). The locations won't appear in the certificate record until after a certificate store inventory has been completed for each store.
FailedStores	An array of GUIDs for the certificates stores for which management jobs to deploy the certificate could not be created.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.14.10 POST Enrollment PFX Replace

The POST /Enrollment/PFX/Replace method is used to replace a certificate in a certificate store. It is intended to be used immediately after using the POST /Enrollment/PFX method to enroll for a PFX using the *Store* value for the *x-certificateformat* header (see POST Enrollment PFX on page 1332) or the POST /Enrollment/Renew method to renew a certificate already in a certificate store. This method returns HTTP 200 OK on a success with a message body containing the failed and succeeded stores.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateStoreManagement: *Schedule*
CertificateEnrollment: *EnrollPFX*

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Note: You could achieve the same end using the *POST /Enrollment/PFX/Deploy* method, but in that case you would need to provide the certificate store GUID(s), the alias of the current certificate in the certificate store(s), the certificate store type(s), and set the overwrite flag to true (as well as the certificate ID of the new certificate). To achieve a replacement with the *POST /Enrollment/PFX/Replace* method you only need to provide the certificate IDs of the certificate being replaced and the new certificate. All the rest of the work is done for you. The certificate will be replaced in all locations in which the certificate is found. If you want to replace the certificate in only some of the locations in which it is found, you will need to use the *POST /Enrollment/PFX/Deploy* method (see POST Enrollment PFX Deploy on page 1347).

Tip: The *POST /Enrollment/PFX/Replace* method must be used within 5 minutes of acquiring a certificate with the *POST /Enrollment/PFX* or POST /Enrollment/Renew method as the same user who executed the certificate request. After 5 minutes, the temporary staging data needed in order to deploy the certificate is automatically cleared and is no longer available for deployment.

Table 338: POST Enrollment PFX Replace Input Parameters

Name	In	Description
ExistingCertificateId	Body	**Required**. The integer of the certificate that will be replaced that is already in the store(s). A management job will be created to replace the certificate in all stores in which it is found. Use the *GET /Certificates* method to determine the certificate ID. This information is also available in the certificate details for a certificate in the Keyfactor Command Management Portal.
CertificateId	Body	**Required***. The integer for the certificate that needs to be deployed. This is returned in the response to the POST /Enrollment/PFX request. Either the *CertificateId* or the *RequestId* is **required** but not both.
RequestId	Body	**Required***. The integer of the request ID for the certificate that needs to be deployed. This is returned in the response to the POST /Enrollment/PFX request. Either the *CertificateId* or the *RequestId* is **required** but not both.
Password	Body	**Required***. A string with a password used to secure the certificate in the certificate store. This field is **required** for store types that require an entry password, such as PEM stores.
JobTime	Body	The date and time when the certificate should be deployed. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z). Dates in the past will cause a management job to be created to run immediately. Dates in the future will result in a management job set to run in the future. The default is to create a management job that runs immediately.

Table 339: POST Enrollment PFX Replace Response Data

Name	Description
SuccessfulStores	An array of GUIDs for the certificates stores for which management jobs to deploy the certificate were successfully created. **Note:** Successful creation of a management job to deploy a certificate to a certificate store does not necessarily mean that a certificate will successfully be deployed to the store. A management job may fail for any number of reasons (e.g. permissions on the store). Use the *GET /Certificates/{id}* method with *includeLocations=true* to confirm that the certificate has successfully been deployed to the target store(s). The locations won't appear in the certificate record until after a certificate store inventory has been completed for each store.
FailedStores	An array of GUIDs for the certificates stores for which management jobs to deploy the certificate could not be created.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.14.11 POST Enrollment Renew

The POST /Enrollment/Renew method is used to enroll for a certificate renewal for a certificate that exists in Keyfactor Command. This method returns HTTP 200 OK on a success with details of the new certificate. For certificates in a certificates store, this method does not automatically deploy the new certificate to the certificate store. In this case, the renew request should be followed by a call to either the POST /Enrollment/PFX/Deploy method or POST /Enrollment/PFX/Replace method to deploy the new certificate to the certificate store.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
Certificates: *Read*
CertificateEnrollment: *EnrollPFX*

Global or container-level schedule permissions for certificate stores are needed to install a certificate generated with this method into a certificate store using the POST /Enrollment/PFX/Deploy method (see POST Enrollment PFX Deploy on page 1347) or POST /Enrollment/PFX/Replace method (see POST Enrollment PFX Replace on page 1352).

Note: As of Keyfactor Command version 10, enrollment (PFX and CSR), renewal, and revocation requests all flow through Keyfactor Command workflow. This will result in no changes to the enrollment, renewal, and revocation user experience unless customizations have been added in workflow (see Workflow Definitions on page 206).

Table 340: POST Enrollment Renew Input Parameters

Name	In	Description
CertificateId	Body	**Required***. The integer for the certificate in Keyfactor Command that needs to be renewed. Either the *CertificateId* or the *Thumbprint* is **required** but not both.
Thumbprint	Body	**Required***. The thumbprint for the certificate that needs to be renewed. Either the *CertificateId* or the *Thumbprint* is **required** but not both.
Timestamp	Body	**Required**. The current date and time. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).
CertificateAuthority	Body	**Required***. A string that sets the name of the certificate authority that will be used to enroll against. The certificate authority name should be provided in *host-name**logical name* format. For example: `corpca01.keyexample.com\\CorpIssuingCA1` This field is **required** if one-click renewal is not supported for the certificate (see GET Enrollment Available Renewal ID on page 1323 or GET Enrollment Available Renewal Thumbprint on page 1324).
Template	Body	**Required***. A string that sets the name of the certificate template that should be used to issue the certificate. The template short name should be used. This field is **required** if one-click renewal is not supported for the certificate (see GET Enrollment Available Renewal ID on page 1323 or GET Enrollment Available Renewal Thumbprint on page 1324).

Table 341: POST Enrollment Renew Response Data

Name	Description
KeyfactorID	ID of the certificate in Keyfactor Command.
KeyfactorRequestID	ID of the request in Keyfactor Command.
Thumbprint	Thumbprint of the certificate.
SerialNumber	Serial number of the certificate.
IssuerDN	Issuer DN of the certificate.
RequestDisposition	State of the request (e.g. issued).
DispositionMessage	Enrollment message (e.g. The private key was successfully retained.).
Password	A password generated for convenience for use on installation to a certificate store. This password may be used when deploying the certificate to a certificate store using the POST /Enrollment/Deploy method, though an alternate password may be used. The passwords do not need to match.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.15 License

The License component of the Keyfactor API is primarily intended to view the current license through the API with the GET /License Method.

Table 342: License Endpoint

Endpoint	Method	Description	Link
/	GET	Returns the current license.	GET License below

3.2.15.1 GET License

The GET /License method is used to view the current license. This method returns HTTP 200 OK on a success with the license details. This method has no input parameters. For more information regarding licensing, see Licensing on page 657 in the *Keyfactor Command Reference Guide*.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SystemSettings: *Read*

Table 343: GET License Response Data

Name	Description
KeyfactorVersion	A string indicating the Keyfactor Command version number in the format: `majorversion.incrementalversion.patchnumber`
LicenseData	An object containing your Keyfactor customer information. License data details are: **Name** / **Description** LicenseId — A string indicating the internal reference GUID of your Keyfactor license. Customer — An object containing identifying information about your organization. **Name** / **Description** Name — A string containing your company name as per your Keyfactor account. Id — An integer containing your Keyfactor account number.
IssuedDate	A string indicating the valid issue date of the license, in UTC.
ExpirationDate	A string indicating the valid expiration date of the license, in UTC.
LicensedProducts	An array containing details of the products and features included in the license. License product and feature details are: **Name** / **Description** ProductId — A string indicating the Keyfactor Command product GUID for the product(s) included in the license. DisplayName — A string indicating the name of the licensed product. For Keyfactor Command, this is "Certificate Management System". MajorRev — A string indicating the valid major release version of the license. MinorRev — A string indicating the valid incremental release version of the license.

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>LicensedFeatures</td><td>An array containing the Keyfactor Command features included in the license.
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>FeatureID</td><td>A string indicating the ID code of feature.</td></tr>
<tr><td>DisplayName</td><td>A string indicating the name of the feature as displayed on the license page in the Management Portal.</td></tr>
<tr><td>Enabled</td><td>A Boolean that indicates whether the feature is enabled (true) or not (false).</td></tr>
<tr><td>Quantity</td><td>An integer indicating one of:
How many of the elements you are licensed for.
For those features which have no licensing limits, null .
Unlimited is indicated by 999999999.</td></tr>
<tr><td>ExpirationDate</td><td>This field is unused and will always return null.</td></tr>
</table>
</td></tr>
</table>
Tip: Currently there is only one licensed product offered, which is Keyfactor Command.
</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.16 MacEnrollment

The MacEnrollment component of the Keyfactor API includes methods to edit and retrieve the configuration for Mac auto-enrollment.

Table 344: MacEnrollment Endpoints

Endpoint	Method	Description	Link
/	GET	Returns the current Mac auto-enrollment configuration.	GET MacEnrollment below
/	PUTT	Updates the Mac auto-enrollment configuration.	PUT MacEnrollment on the next page

3.2.16.1 GET MacEnrollment

The GET /MacEnrollment method is used to retrieve details for the Mac Auto-Enrollment configuration. This method returns HTTP 200 OK on a success with the Mac Auto-Enrollment configuration details. This method has no input parameters.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SystemSettings: *Read*

Table 345: GET MacEnrollment Response Data

Name	Description
Id	An integer indicating the Keyfactor Command referenced ID of the Mac auto-enrollment configuration.
Enabled	An Boolean indicating whether Mac auto-enrollment is configured in the environment (true) or not (false).
Interval	An integer indicating the frequency with which the Mac auto-enrollment agent should check to see if there are new certificates for which to enroll.
UseMetadata	A Boolean indicating whether to automatically associate data in a custom metadata field with an auto-enrolled Mac certificate (true) or not (false). See Certificate Metadata on page 612 in the *Keyfactor Command Reference Guide* for more information about metadata fields.
MetadataField	A string indicating the name of the metadata field to populate for the certificate, if *UseMetadata* is *true*.
MetadataValue	A string indicating the value to populate for the metadata field, if *UseMetadata* is *true*. This may be either a static value (e.g. a fixed string that indicates this certificate was acquired as a result of an auto-enrollment on a Mac), or a variable retrieved from the Mac. In the current version of the agent, only the Mac serial number is available.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.16.2 PUT MacEnrollment

The PUT /MacEnrollment method is used to update the existing Mac Auto-Enrollment configuration. This method returns HTTP 200 OK on a success with the Mac Auto-Enrollment configuration details.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SystemSettings: *Modify*

Warning: Any previously populated fields that are not submitted with their full existing data using this method will be cleared of their existing data. When using this method, you should first do a GET to retrieve all the values for the record you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing.

Table 346: PUT MacEnrollment Response Data

Name	In	Description
Id	Body	An integer indicating the Keyfactor Command referenced ID of the Mac auto-enrollment configuration.
Enabled	Body	An Boolean indicating whether Mac auto-enrollment is configured in the environment (true) or not (false).
Interval	Body	An integer indicating the frequency with which the Mac auto-enrollment agent should check to see if there are new certificates for which to enroll.
UseMetadata	Body	A Boolean indicating whether to automatically associate data in a custom metadata field with an auto-enrolled Mac certificate (true) or not (false). See in the *Keyfactor Command Reference Guide* for more information about metadata fields.
MetadataField	Body	A string indicating the name of the metadata field to populate for the certificate, if *UseMetadata* is *true*.
MetadataValue	Body	A string indicating the value to populate for the metadata field, if *UseMetadata* is *true*. This may be either a static value (e.g. a fixed string that indicates this certificate was acquired as a result of an auto-enrollment on a Mac), or a variable retrieved from the Mac. In the current version of the agent, only the Mac serial number is available.

Table 347: PUT MacEnrollment Response Data

Name	Description
Id	An integer indicating the Keyfactor Command referenced ID of the Mac auto-enrollment configuration.
Enabled	An Boolean indicating whether Mac auto-enrollment is configured in the environment (true) or not (false).
Interval	An integer indicating the frequency with which the Mac auto-enrollment agent should check to see if there are new certificates for which to enroll.
UseMetadata	A Boolean indicating whether to automatically associate data in a custom metadata field with an auto-enrolled Mac certificate (true) or not (false). See Certificate Metadata on page 612 in the *Keyfactor Command Reference Guide* for more information about metadata fields.
MetadataField	A string indicating the name of the metadata field to populate for the certificate, if *UseMetadata* is *true*.
MetadataValue	A string indicating the value to populate for the metadata field, if *UseMetadata* is *true*. This may be either a static value (e.g. a fixed string that indicates this certificate was acquired as a result of an auto-enrollment on a Mac), or a variable retrieved from the Mac. In the current version of the agent, only the Mac serial number is available.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.17 MetadataFields

MetadataFields contains definitions for metadata that can be associated with certificates in Keyfactor Command.

Table 348: MetadataFields Endpoints

Endpoint	Method	Description	Link
/{id}	DELETE	Deletes an existing metadata field.	DELETE MetadataFields ID on the next page
/{id}	GET	Returns detailed information for the specified metadata field.	GET MetadataFields ID on page 1365
/{name}	GET	Returns detailed information for the specified metadata field.	GET MetadataFields Name on page 1368

Endpoint	Method	Description	Link
/{id}/InUse	GET	Returns a Boolean stating whether the metadata type is associated with a certificate.	GET MetadataFields ID InUse on page 1371
/	DELETE	Deletes multiple metadata fields specified in the request body.	DELETE MetadataFields on page 1372
/	GET	Returns all metadata field types with paging (number of pages to return and number of results per page) options.	GET MetadataFields on page 1372
/	POST	Creates a new metadata field using values supplied in the request body.	POST MetadataFields on page 1376
/	PUT	Updates an existing metadata field using values supplied in the request body.	PUT MetadataFields on page 1382

3.2.17.1 DELETE MetadataFields ID

The DELETE /MetadataFields/{id} method is used to delete a metadata field by ID. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: CertificateMetadataTypes: *Modify*

Table 349: DELETE MetadataFields {id} Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID for the metadata field to be deleted. Use the *GET /MetadataFields* method (see GET MetadataFields on page 1372) to retrieve a list of all the metadata fields to determine the metadata field's ID.
Force	Query	A Boolean that sets whether to force deletion of the metadata field even if it is in use by one or more certificates (true) or not (false). The default is *false*. Use the *GET /MetadataFields/{id}/InUse* method (see GET MetadataFields ID InUse on page 1371) to determine whether a metadata field is in use.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.17.2 GET MetadataFields ID

The GET /MetadataFields/{id} method is used to return details for the metadata field with a specified unique ID. This method returns HTTP 200 OK on a success with details for the requested metadata field.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: CertificateMetadataTypes: *Read*

Table 350: GET MetadataFields {id} Input Parameters

Name	In	Description
id	Path	**Required**. An integer indicating the Keyfactor Command reference ID for the metadata field. Use the *GET /MetadataFields* method (see GET MetadataFields on page 1372) to retrieve a list of all the metadata fields to determine the metadata field's ID.

Table 351: GET MetadataFields {id} Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>ID</td><td>An integer indicating the Keyfactor Command reference ID for the metadata field. This ID is automatically set by Keyfactor Command.</td></tr>
<tr><td>Name</td><td>A string indicating the name of the metadata field. This name appears in interfaces where you can use metadata, such as certificate details dialogs, alert dialogs, certificate imports and certificate requests. Once this field has a value associated with it for at least one certificate, you cannot change this name. The metadata name field cannot contain spaces; dashes and underscores are supported.</td></tr>
<tr><td>Description</td><td>A string indicating the description for the metadata field.</td></tr>
<tr><td>DataType</td><td>An integer indicating the data type of the metadata field. Possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>1</td><td>String</td></tr>
<tr><td>2</td><td>Integer</td></tr>
<tr><td>3</td><td>Date</td></tr>
<tr><td>4</td><td>Boolean</td></tr>
<tr><td>5</td><td>Multiple Choice</td></tr>
<tr><td>6</td><td>Big Text</td></tr>
</table></td></tr>
<tr><td>Hint</td><td>A string indicating a short hint for the metadata field. This hint appears in unpopulated metadata string, integer, big text and date fields on editing interfaces to provide the user with a clue as to what type of data should be entered in the field.
This field is only supported for metadata fields with data types string, integer, date or big text.</td></tr>
<tr><td>Validation</td><td>A string containing a regular expression against which data entered in a string field will be validated. When a user enters information in a metadata field that does not match the specified regular expression, he or she will see the warning message specified in the Message field. For example:
<code>^[a-zA-Z0-9'_\.\-]*@(keyexample\.org|keyexample\.com)$</code>
This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly either "@keyexample.org" or "keyexample.com".
This field is only supported for metadata fields with data type string.
Tip: If a template specific option is set for a given metadata field, that takes precedence over the global options. The template-specific regular expression will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Enrollment</td><td>An integer indicating how metadata fields should be handled on the PFX and CSR Enrollment pages. Possible values are:<table><tr><th>Value</th><th>Description</th></tr><tr><td>0</td><td>Optional
Users have the option to either enter a value or not enter a value in the field.</td></tr><tr><td>1</td><td>Required
Users are required to enter data in the field when populating metadata fields on the PFX and CSR Enrollment pages. The field is not required on the certificate details or Add Certificate page.</td></tr><tr><td>2</td><td>Hidden
The field is hidden and does not appear on the PFX and CSR Enrollment pages. This field still appears on the certificate details and the Add Certificate page.</td></tr></table>Tip: If a template-specific handling is set for a given metadata field, it takes precedence over this global setting. The template-specific handling will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).</td></tr>
<tr><td>Message</td><td>A string containing a message to present when a user enters information in a metadata field that does not match the specified regular expression (Validation field).
Tip: If a template-specific regular expression message is set for a given metadata field, it takes precedence over this global regular expression message. The template-specific message will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).</td></tr>
<tr><td>Options</td><td>An array containing a comma separated list of values that should appear in the field dropdown for multiple choice fields.
This field is only supported for metadata fields with data type multiple choice.
Tip: If a template-specific options are set for a given metadata field, these takes precedence over these global options. The template-specific options will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).</td></tr>
<tr><td>DefaultValue</td><td>A string containing a default value with which to pre-populate the metadata field for new certificate requests made using PFX or CSR enrollment. Data type of Email will accept a comma separated list of email addresses (limit 100 characters per email address).
This field is only supported for metadata fields with data types string, integer, Boolean, or multiple choice.</td></tr>
</table>

Name	Description
	Tip: If a template-specific default is set for a given metadata field, it takes precedence over this global default value. The template-specific default will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).
AllowAPI	A Boolean that sets whether methods in the Classic API can be used to manipulate data in the metadata record (true) or not (false). The default is *true*. This setting does not apply to the Keyfactor API. This is considered deprecated and may be removed in a future release.
ExplicitUpdate	A Boolean that sets whether methods in the Classic API must submit an overwrite flag in the request in order to overwrite an existing value in the metadata record (true) or not (false). The default is *false*. This setting does not apply to the Keyfactor API. This is considered deprecated and may be removed in a future release.
DisplayOrder	An integer indicating the order in which the metadata field should be displayed on pages where the metadata fields are displayed (e.g. PFX enrollment, certificate details).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.17.3 GET MetadataFields Name

The GET /MetadataFields/{name} method is used to return details for the metadata field with the specified unique name. This method returns HTTP 200 OK on a success with details for the requested metadata field.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateMetadataTypes: *Read*

Table 352: GET MetadataFields {name} Input Parameters

Name	In	Description
name	Path	**Required**. A string that indicates the name of the metadata field. This value is not case sensitive.

Table 353: GET MetadataFields {name} Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>ID</td><td>An integer indicating the Keyfactor Command reference ID for the metadata field. This ID is automatically set by Keyfactor Command.</td></tr>
<tr><td>Name</td><td>A string indicating the name of the metadata field. This name appears in interfaces where you can use metadata, such as certificate details dialogs, alert dialogs, certificate imports and certificate requests. Once this field has a value associated with it for at least one certificate, you cannot change this name. The metadata name field cannot contain spaces; dashes and underscores are supported.</td></tr>
<tr><td>Description</td><td>A string indicating the description for the metadata field.</td></tr>
<tr><td>DataType</td><td>An integer indicating the data type of the metadata field. Possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>1</td><td>String</td></tr>
<tr><td>2</td><td>Integer</td></tr>
<tr><td>3</td><td>Date</td></tr>
<tr><td>4</td><td>Boolean</td></tr>
<tr><td>5</td><td>Multiple Choice</td></tr>
<tr><td>6</td><td>Big Text</td></tr>
</table></td></tr>
<tr><td>Hint</td><td>A string indicating a short hint for the metadata field. This hint appears in unpopulated metadata string, integer, big text and date fields on editing interfaces to provide the user with a clue as to what type of data should be entered in the field.
This field is only supported for metadata fields with data types string, integer, date or big text.</td></tr>
<tr><td>Validation</td><td>A string containing a regular expression against which data entered in a string field will be validated. When a user enters information in a metadata field that does not match the specified regular expression, he or she will see the warning message specified in the Message field. For example:
<code>^[a-zA-Z0-9'_\.\-]*@(keyexample\.org|keyexample\.com)$</code>
This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly either "@keyexample.org" or "keyexample.com".
This field is only supported for metadata fields with data type string.
Tip: If a template specific option is set for a given metadata field, that takes precedence over the global options. The template-specific regular expression will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Enrollment</td><td>An integer indicating how metadata fields should be handled on the PFX and CSR Enrollment pages. Possible values are:<table><tr><th>Value</th><th>Description</th></tr><tr><td>0</td><td>Optional
Users have the option to either enter a value or not enter a value in the field.</td></tr><tr><td>1</td><td>Required
Users are required to enter data in the field when populating metadata fields on the PFX and CSR Enrollment pages. The field is not required on the certificate details or Add Certificate page.</td></tr><tr><td>2</td><td>Hidden
The field is hidden and does not appear on the PFX and CSR Enrollment pages. This field still appears on the certificate details and the Add Certificate page.</td></tr></table>Tip: If a template-specific handling is set for a given metadata field, it takes precedence over this global setting. The template-specific handling will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).</td></tr>
<tr><td>Message</td><td>A string containing a message to present when a user enters information in a metadata field that does not match the specified regular expression (Validation field).
Tip: If a template-specific regular expression message is set for a given metadata field, it takes precedence over this global regular expression message. The template-specific message will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).</td></tr>
<tr><td>Options</td><td>An array containing a comma separated list of values that should appear in the field dropdown for multiple choice fields.
This field is only supported for metadata fields with data type multiple choice.
Tip: If a template-specific options are set for a given metadata field, these takes precedence over these global options. The template-specific options will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).</td></tr>
<tr><td>DefaultValue</td><td>A string containing a default value with which to pre-populate the metadata field for new certificate requests made using PFX or CSR enrollment. Data type of Email will accept a comma separated list of email addresses (limit 100 characters per email address).
This field is only supported for metadata fields with data types string, integer, Boolean, or multiple choice.</td></tr>
</table>

Name	Description
	Tip: If a template-specific default is set for a given metadata field, it takes precedence over this global default value. The template-specific default will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).
AllowAPI	A Boolean that sets whether methods in the Classic API can be used to manipulate data in the metadata record (true) or not (false). The default is *true*. This setting does not apply to the Keyfactor API. This is considered deprecated and may be removed in a future release.
ExplicitUpdate	A Boolean that sets whether methods in the Classic API must submit an overwrite flag in the request in order to overwrite an existing value in the metadata record (true) or not (false). The default is *false*. This setting does not apply to the Keyfactor API. This is considered deprecated and may be removed in a future release.
DisplayOrder	An integer indicating the order in which the metadata field should be displayed on pages where the metadata fields are displayed (e.g. PFX enrollment, certificate details).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.17.4 GET MetadataFields ID InUse

The GET /MetadataFields/{id}/InUse method is used to return a Boolean indicating whether the specified metadata field contains any data for any of the certificates in Keyfactor Command. This is useful to determine before attempting to delete a metadata field. This method returns HTTP 200 OK on a success with a value of true or false.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateMetadataTypes: *Read*

Table 354: GET MetadataFields {id} In Use Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID for the metadata field. Use the *GET /MetadataFields* method (see GET MetadataFields on the next page) to retrieve a list of all the metadata fields to determine the metadata field's ID.

Table 355: GET MetadataFields {id} In Use Response Data

Name	Description
	A Boolean that indicates whether the specified metadata field contains data for any certificates within Keyfactor Command (true) or not (false). This value is returned without a parameter name.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.17.5 DELETE MetadataFields

The DELETE /MetadataFields method is used to delete multiple metadata fields in one request. The metadata fields IDs should be supplied in the request body as a JSON array of integers. Delete operations will continue until the entire array of IDs has been processed. Note that metadata fields that are in use for any certificate cannot be deleted unless the force=true parameter is included in the request. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateMetadataTypes: *Modify*

Table 356: DELETE MetadataFields Input Parameters

Name	In	Description
ids	Body	**Required**. An array of Keyfactor Command reference IDs for the metadata fields to be deleted. Use the *GET /MetadataFields* method (see GET MetadataFields below) to retrieve a list of all the metadata fields to determine the metadata field IDs.
Force	Query	A Boolean that sets whether to force deletion of the metadata fields even if they are in use (true) or not (false). The default is *False*. Use the *GET /MetadataFields/{id}/InUse* method (see GET MetadataFields ID InUse on the previous page) to determine whether a metadata field is in use.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.17.6 GET MetadataFields

The GET /MetadataFields method is used to return a list of all metadata fields. This method returns HTTP 200 OK on a success with details for the metadata fields.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: CertificateMetadataTypes: *Read*

Table 357: GET MetadataFields Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Using the Logons Search on page 542. The query fields supported for this endpoint are: • *Name*
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *DisplayOrder*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

<tr><td>Enrollment</td><td>An integer indicating how metadata fields should be handled on the PFX and CSR Enrollment pages. Possible values are:<table><tr><th>Value</th><th>Description</th></tr><tr><td>0</td><td>Optional
Users have the option to either enter a value or not enter a value in the field.</td></tr><tr><td>1</td><td>Required
Users are required to enter data in the field when populating metadata fields on the PFX and CSR Enrollment pages. The field is not required on the certificate details or Add Certificate page.</td></tr><tr><td>2</td><td>Hidden
The field is hidden and does not appear on the PFX and CSR Enrollment pages. This field still appears on the certificate details and the Add Certificate page.</td></tr></table>Tip: If a template-specific handling is set for a given metadata field, it takes precedence over this global setting. The template-specific handling will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).</td></tr>
<tr><td>Message</td><td>A string containing a message to present when a user enters information in a metadata field that does not match the specified regular expression (Validation field).
Tip: If a template-specific regular expression message is set for a given metadata field, it takes precedence over this global regular expression message. The template-specific message will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).</td></tr>
<tr><td>Options</td><td>An array containing a comma separated list of values that should appear in the field dropdown for multiple choice fields.
This field is only supported for metadata fields with data type multiple choice.
Tip: If a template-specific options are set for a given metadata field, these takes precedence over these global options. The template-specific options will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).</td></tr>
<tr><td>DefaultValue</td><td>A string containing a default value with which to pre-populate the metadata field for new certificate requests made using PFX or CSR enrollment. Data type of Email will accept a comma separated list of email addresses (limit 100 characters per email address).
This field is only supported for metadata fields with data types string, integer, Boolean, or multiple choice.</td></tr>
</table>

Name	Description
	Tip: If a template-specific default is set for a given metadata field, it takes precedence over this global default value. The template-specific default will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).
AllowAPI	A Boolean that sets whether methods in the Classic API can be used to manipulate data in the metadata record (true) or not (false). The default is *true*. This setting does not apply to the Keyfactor API. This is considered deprecated and may be removed in a future release.
ExplicitUpdate	A Boolean that sets whether methods in the Classic API must submit an overwrite flag in the request in order to overwrite an existing value in the metadata record (true) or not (false). The default is *false*. This setting does not apply to the Keyfactor API. This is considered deprecated and may be removed in a future release.
DisplayOrder	An integer indicating the order in which the metadata field should be displayed on pages where the metadata fields are displayed (e.g. PFX enrollment, certificate details).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.17.7 POST MetadataFields

The POST /MetadataFields method is used to create a new metadata field in Keyfactor Command. This method returns HTTP 200 OK on a success with details of the new metadata field.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateMetadataTypes: *Modify*

Table 359: POST MetadataFields Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>Name</td><td>Body</td><td>Required. A string indicating the name of the metadata field. <table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Enrollment</td><td>An integer indicating how metadata fields should be handled on the PFX and CSR Enrollment pages. Possible values are:<table><tr><th>Value</th><th>Description</th></tr><tr><td>0</td><td>Optional
Users have the option to either enter a value or not enter a value in the field.</td></tr><tr><td>1</td><td>Required
Users are required to enter data in the field when populating metadata fields on the PFX and CSR Enrollment pages. The field is not required on the certificate details or Add Certificate page.</td></tr><tr><td>2</td><td>Hidden
The field is hidden and does not appear on the PFX and CSR Enrollment pages. This field still appears on the certificate details and the Add Certificate page.</td></tr></table>Tip: If a template-specific handling is set for a given metadata field, it takes precedence over this global setting. The template-specific handling will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).</td></tr>
<tr><td>Message</td><td>A string containing a message to present when a user enters information in a metadata field that does not match the specified regular expression (Validation field).
Tip: If a template-specific regular expression message is set for a given metadata field, it takes precedence over this global regular expression message. The template-specific message will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).</td></tr>
<tr><td>Options</td><td>An array containing a comma separated list of values that should appear in the field dropdown for multiple choice fields.
This field is only supported for metadata fields with data type multiple choice.
Tip: If a template-specific options are set for a given metadata field, these takes precedence over these global options. The template-specific options will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).</td></tr>
<tr><td>DefaultValue</td><td>A string containing a default value with which to pre-populate the metadata field for new certificate requests made using PFX or CSR enrollment. Data type of Email will accept a comma separated list of email addresses (limit 100 characters per email address).
This field is only supported for metadata fields with data types string, integer, Boolean, or multiple choice.</td></tr>
</table>

Name	Description
	Tip: If a template-specific default is set for a given metadata field, it takes precedence over this global default value. The template-specific default will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).
AllowAPI	A Boolean that sets whether methods in the Classic API can be used to manipulate data in the metadata record (true) or not (false). The default is *true*. This setting does not apply to the Keyfactor API. This is considered deprecated and may be removed in a future release.
ExplicitUpdate	A Boolean that sets whether methods in the Classic API must submit an overwrite flag in the request in order to overwrite an existing value in the metadata record (true) or not (false). The default is *false*. This setting does not apply to the Keyfactor API. This is considered deprecated and may be removed in a future release.
DisplayOrder	An integer indicating the order in which the metadata field should be displayed on pages where the metadata fields are displayed (e.g. PFX enrollment, certificate details).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.17.8 PUT MetadataFields

The PUT /MetadataFields method is used to update an existing metadata field in Keyfactor Command. This method returns HTTP 200 OK on a success with details of the updated metadata field.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateMetadataTypes: *Modify*

Warning: Any previously populated fields that are not submitted with their full existing data using this method will be cleared of their existing data. When using this method, you should first do a GET to retrieve all the values for the record you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing.

Table 361: PUT MetadataFields Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>ID</td><td>Body</td><td>Required. An integer indicating the Keyfactor Command reference ID for the metadata field. This ID is automatically set by Keyfactor Command.</td></tr>
<tr><td>Name</td><td>Body</td><td>Required. A string indicating the name of the metadata field. This name appears in interfaces where you can use metadata, such as certificate details dialogs, alert dialogs, certificate imports and certificate requests. Once this field has a value associated with it for at least one certificate, you cannot change this name. The metadata name field cannot contain spaces; dashes and underscores are supported.</td></tr>
<tr><td>Description</td><td>Body</td><td>Required. A string indicating the description for the metadata field.</td></tr>
<tr><td>DataType</td><td>Body</td><td>Required. An integer indicating the data type of the metadata field. Possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>1</td><td>String</td></tr>
<tr><td>2</td><td>Integer</td></tr>
<tr><td>3</td><td>Date</td></tr>
<tr><td>4</td><td>Boolean</td></tr>
<tr><td>5</td><td>Multiple Choice</td></tr>
<tr><td>6</td><td>Big Text</td></tr>
</table></td></tr>
<tr><td>Hint</td><td>Body</td><td>A string indicating a short hint for the metadata field. This hint appears in unpopulated metadata string, integer, big text and date fields on editing interfaces to provide the user with a clue as to what type of data should be entered in the field.
This field is only supported for metadata fields with data types string, integer, date or big text.</td></tr>
<tr><td>Validation</td><td>Body</td><td>A string containing a regular expression against which data entered in a string field will be validated. When a user enters information in a metadata field that does not match the specified regular expression, he or she will see the warning message specified in the Message field. For example:
<code>^[a-zA-Z0-9'_\.\-]*@(keyexample\.org|keyexample\.com)$</code>
This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly either "@keyexample.org" or "keyexample.com".
This field is only supported for metadata fields with data type string.</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>Tip: If a template specific option is set for a given metadata field, that takes precedence over the global options. The template-specific regular expression will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).</td></tr>
<tr><td>Enrollment</td><td>Body</td><td>An integer indicating how metadata fields should be handled on the PFX and CSR Enrollment pages. Possible values are:
<table><tr><th>Value</th><th>Description</th></tr><tr><td>0</td><td>Optional
Users have the option to either enter a value or not enter a value in the field.</td></tr><tr><td>1</td><td>Required
Users are required to enter data in the field when populating metadata fields on the PFX and CSR Enrollment pages. The field is not required on the certificate details or Add Certificate page.</td></tr><tr><td>2</td><td>Hidden
The field is hidden and does not appear on the PFX and CSR Enrollment pages. This field still appears on the certificate details and the Add Certificate page.</td></tr></table>The default is optional.
Tip: If a template-specific handling is set for a given metadata field, it takes precedence over this global setting. The template-specific handling will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).</td></tr>
<tr><td>Message</td><td>Body</td><td>A string containing a message to present when a user enters information in a metadata field that does not match the specified regular expression (Validation field).
Tip: If a template-specific regular expression message is set for a given metadata field, it takes precedence over this global regular expression message. The template-specific message will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).</td></tr>
<tr><td>Options</td><td>Body</td><td>An array containing a comma separated list of values that should appear in the field dropdown for multiple choice fields.
This field is required for metadata fields with data type multiple choice. For other data types, it will be ignored.</td></tr>
</table>

Name	In	Description
		Tip: If a template-specific options are set for a given metadata field, these takes precedence over these global options. The template-specific options will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).
DefaultValue	Body	A string containing a default value with which to pre-populate the metadata field for new certificate requests made using PFX or CSR enrollment. Data type of Email will accept a comma separated list of email addresses (limit 100 characters per email address). This field is only supported for metadata fields with data types *string*, *integer*, *Boolean*, or *multiple choice*. **Tip:** If a template-specific default is set for a given metadata field, it takes precedence over this global default value. The template-specific default will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).
AllowAPI	Body	A Boolean that sets whether methods in the Classic API can be used to manipulate data in the metadata record (true) or not (false). The default is *true*. This setting does not apply to the Keyfactor API. This is considered deprecated and may be removed in a future release.
ExplicitUpdate	Body	A Boolean that sets whether methods in the Classic API must submit an overwrite flag in the request in order to overwrite an existing value in the metadata record (true) or not (false). The default is *false*. This setting does not apply to the Keyfactor API. This is considered deprecated and may be removed in a future release.
DisplayOrder	Body	An integer indicating the order in which the metadata field should be displayed on pages where the metadata fields are displayed (e.g. PFX enrollment, certificate details).

Table 362: PUT MetadataFields Response Data

Name	Description
ID	An integer indicating the Keyfactor Command reference ID for the metadata field. This ID is automatically set by Keyfactor Command.
Name	A string indicating the name of the metadata field. This name appears in interfaces where you can use metadata, such as certificate details dialogs, alert dialogs, certificate imports and certificate requests. Once this field has a value associated with it for at least one certificate, you cannot change this name. The metadata name field cannot contain spaces; dashes and underscores are supported.
Description	A string indicating the description for the metadata field.
DataType	An integer indicating the data type of the metadata field. Possible values are: **Value** / **Description** 1 / String 2 / Integer 3 / Date 4 / Boolean 5 / Multiple Choice 6 / Big Text
Hint	A string indicating a short hint for the metadata field. This hint appears in unpopulated metadata string, integer, big text and date fields on editing interfaces to provide the user with a clue as to what type of data should be entered in the field. This field is only supported for metadata fields with data types *string*, *integer*, *date* or *big text*.
Validation	A string containing a regular expression against which data entered in a string field will be validated. When a user enters information in a metadata field that does not match the specified regular expression, he or she will see the warning message specified in the *Message* field. For example: `^[a-zA-Z0-9'_\.\-]*@(keyexample\.org|keyexample\.com)$` This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly either "@keyexample.org" or "keyexample.com". This field is only supported for metadata fields with data type *string*. **Tip:** If a template specific option is set for a given metadata field, that takes precedence over the global options. The template-specific regular expression will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Enrollment</td><td>An integer indicating how metadata fields should be handled on the PFX and CSR Enrollment pages. Possible values are:<table><tr><th>Value</th><th>Description</th></tr><tr><td>0</td><td>Optional
Users have the option to either enter a value or not enter a value in the field.</td></tr><tr><td>1</td><td>Required
Users are required to enter data in the field when populating metadata fields on the PFX and CSR Enrollment pages. The field is not required on the certificate details or Add Certificate page.</td></tr><tr><td>2</td><td>Hidden
The field is hidden and does not appear on the PFX and CSR Enrollment pages. This field still appears on the certificate details and the Add Certificate page.</td></tr></table>Tip: If a template-specific handling is set for a given metadata field, it takes precedence over this global setting. The template-specific handling will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).</td></tr>
<tr><td>Message</td><td>A string containing a message to present when a user enters information in a metadata field that does not match the specified regular expression (Validation field).
Tip: If a template-specific regular expression message is set for a given metadata field, it takes precedence over this global regular expression message. The template-specific message will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).</td></tr>
<tr><td>Options</td><td>An array containing a comma separated list of values that should appear in the field dropdown for multiple choice fields.
This field is only supported for metadata fields with data type multiple choice.
Tip: If a template-specific options are set for a given metadata field, these takes precedence over these global options. The template-specific options will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).</td></tr>
<tr><td>DefaultValue</td><td>A string containing a default value with which to pre-populate the metadata field for new certificate requests made using PFX or CSR enrollment. Data type of Email will accept a comma separated list of email addresses (limit 100 characters per email address).
This field is only supported for metadata fields with data types string, integer, Boolean, or multiple choice.</td></tr>
</table>

Name	Description
	Tip: If a template-specific default is set for a given metadata field, it takes precedence over this global default value. The template-specific default will be used in PFX and CSR enrollment requests using that template (see GET Templates ID on page 1889).
AllowAPI	A Boolean that sets whether methods in the Classic API can be used to manipulate data in the metadata record (true) or not (false). The default is *true*. This setting does not apply to the Keyfactor API. This is considered deprecated and may be removed in a future release.
ExplicitUpdate	A Boolean that sets whether methods in the Classic API must submit an overwrite flag in the request in order to overwrite an existing value in the metadata record (true) or not (false). The default is *false*. This setting does not apply to the Keyfactor API. This is considered deprecated and may be removed in a future release.
DisplayOrder	An integer indicating the order in which the metadata field should be displayed on pages where the metadata fields are displayed (e.g. PFX enrollment, certificate details).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.18 Monitoring Revocation

The Monitoring Revocation component of the Keyfactor API provides a set of methods to support management of CRL and OCSP monitoring locations.

Table 363: Monitoring Revocation Endpoints

Endpoint	Method	Description	Link
/{id}	DELETE	Deletes the revocation monitoring location with the specified ID.	DELETE Monitoring Revocation ID on the next page
/{id}	GET	Returns details for the revocation monitoring location with the specified ID.	GET Monitoring Revocation ID on the next page
/	PUT	Edits the revocation monitoring location with the specified ID.	PUT Monitoring Revocation on page 1403
/	GET	Returns details for all revocation monitoring location according to the provided filter and output para-	GET Monitoring Revocation on page 1393

Endpoint	Method	Description	Link
		meters.	
/	POST	Creates a new revocation monitoring location.	POST Monitoring Revocation on page 1397
/ResolveOSCP	POST	Resolves the given OCSP certificate authority.	POST Monitoring Resolve OSCP on page 1409
/Test	POST	Tests the revocation monitoring alert with the specified ID.	POST Monitoring Revocation Test on page 1410
/TestAll	POST	Tests the revocation monitoring alerts.	POST Monitoring Revocation Test All on page 1412

3.2.18.1 DELETE Monitoring Revocation ID

The DELETE Monitoring/Revocation/{id} method is used to delete the revocation monitoring location with the specified ID. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: WorkflowManagement: *Modify*

Table 364: DELETE Monitoring Revocation {id} Input Parameters

Name	In	Description
id	Path	**Required**. An integer that specifies the ID of the revocation monitoring location. Use the *GET /Monitoring/Revocation* method (see GET Monitoring Revocation on page 1393) to retrieve a list of all the revocation monitoring locations to determine the ID.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.18.2 GET Monitoring Revocation ID

The GET /Monitoring/Revocation/{id} method is used to retrieve the revocation monitoring location with the specified ID. This method returns HTTP 200 OK on a success with details of the location.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: WorkflowManagement: *Read*

Table 365: GET Monitoring Revocation {id} Input Parameters

Name	In	Description
id	Path	**Required**. An integer that specifies the ID of the revocation monitoring location. Use the *GET /Monitoring/Revocation* method (see GET Monitoring Revocation on page 1393) to retrieve a list of all the revocation monitoring locations to determine the ID.

Table 366: GET Monitoring Revocation {id} Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of the revocation monitoring location.</td></tr>
<tr><td>Name</td><td>A string indicating the name of the revocation monitoring location.</td></tr>
<tr><td>EndpointType</td><td>A string indicating the type of revocation monitoring endpoint: OCSP or CRL.</td></tr>
<tr><td>Location</td><td>A string indicating the location for the revocation monitoring endpoint.
For CRL endpoints, this can be either an HTTP location or an LDAP location. Be sure to monitor the CRL locations that are in use by applications in your environment—if you're monitoring LDAP locations but applications are using an HTTP location, you're not going to receive any warning if a CRL fails to publish to the HTTP location.
For OCSP endpoints, this is the full URL to the OCSP responder servicing this certificate authority's CRL.</td></tr>
<tr><td>Email</td><td>For CRL endpoints only, an array indicating the email recipients and reminder schedule for reminder alerts. Email reminder details are:<table><tr><th>Value</th><th>Description</th></tr><tr><td>EnableReminder</td><td>A Boolean indicating whether to send email reminders for this location (true) or not (false).</td></tr><tr><td>WarningDays</td><td>An integer indicating the number of days before expiration to send the warning email.</td></tr><tr><td>Recipients</td><td>An object containing a list of strings with email addresses to which the email reminders should be sent.</td></tr></table></td></tr>
<tr><td>Dashboard</td><td>An array indicating the configuration for display on the dashboard. Dashboard details are:<table><tr><th>Value</th><th>Description</th></tr><tr><td>Show</td><td>A Boolean indicating whether to show this revocation monitoring location on the Revocation Monitoring dashboard (true) or not (false).</td></tr><tr><td>WarningHours</td><td>An integer indicating the number of hours prior to expiration when the location begins to appear in a warning state on the dashboard.
WarningHours is required if Show is set to true and EndpointType is CRL.
WarningHours is not supported for EndpointType OCSP.
If the Days or Weeks value is selected in the Management Portal, it will be converted to hours when stored in the database.</td></tr></table></td></tr>
<tr><td>Schedule</td><td>An array containing the inventory schedule set for the revocation monitoring location. Supported</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>schedules are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
<tr><td>Interval</td><td>A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Minutes</td><td>An integer indicating the number of minutes between each interval.</td></tr>
</table>
For example, every hour:
<pre>"Interval": {
   "Minutes": 60
}</pre></td></tr>
<tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, daily at 11:30 pm:
<pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre></td></tr>
</table>

Note: Although the Swagger Example Value may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint.</td></tr>
<tr><td>OCSPParameters</td><td>For OCSP endpoints only, an array indicating the OCSP endpoint configuration. OCSP endpoint details are:</td></tr>
</table>

Name	Description
	<table><tr><th>Value</th><th>Description</th></tr><tr><td>CertificateAuthorityId</td><td>An integer indicating the Keyfactor Command reference ID of the CA in the database. Use the *GET /CertificateAuthority* method (see GET Certificate Authority on page 1008) to retrieve a list of all the CAs to determine the ID. This value will be null on a response if the endpoint was configured using the *CertificateContents* option.</td></tr><tr><td>AuthorityName</td><td>A string indicating the distinguished name of the CA. For example: <code>CN=CorpIssuingCA1, DC=keyexample, DC=com</code></td></tr><tr><td>AuthorityNameId</td><td>A base 64 encoded SHA1 hash of the *AuthorityName*.</td></tr><tr><td>AuthorityKeyId</td><td>A base 64 encoded SHA1 hash of the CA certificate's public key. This value is found in the CA's certificate as the Subject Key Identifier (SKID).</td></tr><tr><td>SampleSerialNumber</td><td>A string indicating the serial number of the CA.</td></tr></table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.18.3 GET Monitoring Revocation

The GET /Monitoring/Revocation method is used to retrieve all revocation monitoring locations. This method returns HTTP 200 OK on a success with details of both OCSP and CRL revocation endpoint configurations.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
WorkflowManagement: *Read*

Table 367: GET Monitoring Revocation Input Parameters

Name	In	Description

queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Certificate Search Page on page 31. The query fields supported for this endpoint are:
		• *DashboardWarningValue* (WarningHours value)
		• *DisplayName* (Name)
		• *EndpointType* (1-CRL, 2-OCSP)
		• *SendWarning* (emailreminder) (true, false)
		• *ShowOnDashboard* (true, false)
		• *Url*
		• *WarningDays*
		
		Tip: To return all revocation monitoring locations of type CRL, use the following query:
		`EndpointType -eq 1`
		To return locations of type OCSP, use this query:
		`EndpointType -eq 2`

pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *Name*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 368: GET Monitoring Revocation Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of the revocation monitoring location.</td></tr>
<tr><td>Name</td><td>A string indicating the name of the revocation monitoring location.</td></tr>
<tr><td>EndpointType</td><td>A string indicating the type of revocation monitoring endpoint: OCSP or CRL.</td></tr>
<tr><td>Location</td><td>A string indicating the location for the revocation monitoring endpoint.
For CRL endpoints, this can be either an HTTP location or an LDAP location. Be sure to monitor the CRL locations that are in use by applications in your environment—if you're monitoring LDAP locations but applications are using an HTTP location, you're not going to receive any warning if a CRL fails to publish to the HTTP location.
For OCSP endpoints, this is the full URL to the OCSP responder servicing this certificate authority's CRL.</td></tr>

<pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre></td></tr>
</table>
Note: Although the Swagger Example Value may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint.</td></tr>
<tr><td>OCSPParameters</td><td>For OCSP endpoints only, an array indicating the OCSP endpoint configuration. OCSP endpoint details are:</td></tr>
</table>

Name	Description
	<table><tr><th>Value</th><th>Description</th></tr><tr><td>CertificateAuthorityId</td><td>An integer indicating the Keyfactor Command reference ID of the CA in the database. Use the *GET /CertificateAuthority* method (see GET Certificate Authority on page 1008) to retrieve a list of all the CAs to determine the ID. This value will be null on a response if the endpoint was configured using the *CertificateContents* option.</td></tr><tr><td>AuthorityName</td><td>A string indicating the distinguished name of the CA. For example: <code>CN=CorpIssuingCA1, DC=keyexample, DC=com</code></td></tr><tr><td>AuthorityNameId</td><td>A base 64 encoded SHA1 hash of the *AuthorityName*.</td></tr><tr><td>AuthorityKeyId</td><td>A base 64 encoded SHA1 hash of the CA certificate's public key. This value is found in the CA's certificate as the Subject Key Identifier (SKID).</td></tr><tr><td>SampleSerialNumber</td><td>A string indicating the serial number of the CA.</td></tr></table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.18.4 POST Monitoring Revocation

The POST /Monitoring/Revocation method is used to add a revocation monitoring location. This method returns HTTP 200 OK on a success with details of the location.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
WorkflowManagement: *Modify*

Table 369: POST Monitoring Revocation Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>Id</td><td>Path</td><td>Required. An integer indicating the Keyfactor Command reference ID of the revocation monitoring location.</td></tr>
<tr><td>Name</td><td>Body</td><td>Required. A string indicating the name of the revocation monitoring location.</td></tr>
<tr><td>EndpointType</td><td>Body</td><td>Required. A string indicating the type of revocation monitoring endpoint: OCSP or CRL.</td></tr>
<tr><td>Location</td><td>Body</td><td>Required. A string indicating the location for the revocation monitoring endpoint.
For CRL endpoints, this can be either an HTTP location or an LDAP location. Be sure to monitor the CRL locations that are in use by applications in your environment—if you're monitoring LDAP locations but applications are using an HTTP location, you're not going to receive any warning if a CRL fails to publish to the HTTP location.
Important: Because a "+" (plus sign) in a URL can represent either a space or a "+" Keyfactor Command has chosen to read "+" as a space. For CRL URLs that require a "+" (plus sign), rather than a space, replace plus signs in your CRL's URL with "<code>%2B</code>". Only replace the plus signs you don't wish to be treated as a space.
For OCSP endpoints, this is the full URL to the OCSP responder servicing this certificate authority's CRL.</td></tr>
<tr><td>Email</td><td>Body</td><td>Required*. for CRL endpoints. For CRL endpoints only, an array indicating the email recipients and reminder schedule for reminder alerts. Email reminder details are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>EnableReminder</td><td>A Boolean indicating whether to send email reminders for this location (true) or not (false). The default is false.</td></tr>
<tr><td>WarningDays</td><td>An integer indicating the number of days before expiration to send the warning email.</td></tr>
<tr><td>Recipients</td><td>An object containing a list of strings with email addresses to which the email reminders should be sent.</td></tr>
</table></td></tr>
<tr><td>Dashboard</td><td>Body</td><td>Required. An array indicating the configuration for display on the dashboard. Dashboard details are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>Show</td><td>Required. A Boolean indicating whether to show this revocation monitoring location on the Revocation Monitoring dashboard</td></tr>
</table></td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>(true) or not (false). The default is false.</td></tr>
<tr><td>WarningHours</td><td>Required*. An integer indicating the number of hours prior to expiration when the location begins to appear in a warning state on the dashboard.
WarningHours is required if Show is set to true and EndpointType is CRL.
WarningHours is not supported for EndpointType OCSP.
If the Days or Weeks value is selected in the Management Portal, it will be converted to hours when stored in the database.</td></tr>
</table>
</td></tr>
<tr><td>Schedule</td><td>Body</td><td>An array containing the inventory schedule set for the revocation monitoring location. Supported schedules are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
<tr><td>Interval</td><td>A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Minutes</td><td>An integer indicating the number of minutes between each interval.</td></tr>
</table>
For example, every hour:
<pre>"Interval": {
   "Minutes": 60
}</pre></td></tr>
<tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, daily at 11:30 pm:
<pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre>
</td></tr>
</table>
Note: Although the Swagger Example Value may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint.
</td></tr>
<tr><td>OCSPParameters</td><td>Body</td><td>Required*. for OCSP endpoints. For OCSP endpoints only, an array indicating the OCSP endpoint configuration. OCSP endpoint details are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>CertificateContents</td><td>A string indicating the certificate contents.</td></tr>
<tr><td>CertificateAuthorityId</td><td>An integer indicating the Keyfactor Command reference ID of the CA in the database.
Use the GET /CertificateAuthority method (see <a>GET Certificate Authority on page 1008) to retrieve a list of all the CAs to determine the ID.</td></tr>
</table>
</td></tr>
</table>

Table 370: POST Monitoring Revocation Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Name</td><td>A string indicating the name of the revocation monitoring location.</td></tr>
<tr><td>EndpointType</td><td>A string indicating the type of revocation monitoring endpoint: OCSP or CRL.</td></tr>
<tr><td>Location</td><td>A string indicating the location for the revocation monitoring endpoint.
For CRL endpoints, this can be either an HTTP location or an LDAP location. Be sure to monitor the CRL locations that are in use by applications in your environment—if you're monitoring LDAP locations but applications are using an HTTP location, you're not going to receive any warning if a CRL fails to publish to the HTTP location.
For OCSP endpoints, this is the full URL to the OCSP responder servicing this certificate authority's CRL.</td></tr>
<tr><td>Email</td><td>For CRL endpoints only, an array indicating the email recipients and reminder schedule for reminder alerts. Email reminder details are:<table><tr><th>Value</th><th>Description</th></tr><tr><td>EnableReminder</td><td>A Boolean indicating whether to send email reminders for this location (true) or not (false).</td></tr><tr><td>WarningDays</td><td>An integer indicating the number of days before expiration to send the warning email.</td></tr><tr><td>Recipients</td><td>An object containing a list of strings with email addresses to which the email reminders should be sent.</td></tr></table></td></tr>

This value will be null on a response if the endpoint was configured using the *CertificateContents* option.</td></tr><tr><td>AuthorityName</td><td>A string indicating the distinguished name of the CA. For example: <code>CN=CorpIssuingCA1, DC=keyexample, DC=com</code></td></tr><tr><td>AuthorityNameId</td><td>A base 64 encoded SHA1 hash of the *AuthorityName*.</td></tr><tr><td>AuthorityKeyId</td><td>A base 64 encoded SHA1 hash of the CA certificate's public key. This value is found in the CA's certificate as the Subject Key Identifier (SKID).</td></tr><tr><td>SampleSerialNumber</td><td>A string indicating the serial number of the CA.</td></tr></table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.18.5 PUT Monitoring Revocation

The PUT /Monitoring/Revocation method is used to modify the revocation monitoring location. This method returns HTTP 200 OK on a success with details of the location.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
WorkflowManagement: *Modify*

Warning: Any previously populated fields that are not submitted with their full existing data using this method will be cleared of their existing data. When using this method, you should first do a GET to retrieve all the values for the record you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing.

Table 371: PUT Monitoring Revocation {id}Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>Id</td><td>Path</td><td>Required. An integer indicating the Keyfactor Command reference ID of the revocation monitoring location.</td></tr>
<tr><td>Name</td><td>Body</td><td>Required. A string indicating the name of the revocation monitoring location.</td></tr>
<tr><td>EndpointType</td><td>Body</td><td>Required. A string indicating the type of revocation monitoring endpoint: OCSP or CRL.</td></tr>
<tr><td>Location</td><td>Body</td><td>Required. A string indicating the location for the revocation monitoring endpoint.
For CRL endpoints, this can be either an HTTP location or an LDAP location. Be sure to monitor the CRL locations that are in use by applications in your environment—if you're monitoring LDAP locations but applications are using an HTTP location, you're not going to receive any warning if a CRL fails to publish to the HTTP location.
Important: Because a "+" (plus sign) in a URL can represent either a space or a "+" Keyfactor Command has chosen to read "+" as a space. For CRL URLs that require a "+" (plus sign), rather than a space, replace plus signs in your CRL's URL with "<code>%2B</code>". Only replace the plus signs you don't wish to be treated as a space.
For OCSP endpoints, this is the full URL to the OCSP responder servicing this certificate authority's CRL.</td></tr>
<tr><td>Email</td><td>Body</td><td>Required*. for CRL endpoints. For CRL endpoints only, an array indicating the email recipients and reminder schedule for reminder alerts. Email reminder details are:<table><tr><th>Value</th><th>Description</th></tr><tr><td>EnableReminder</td><td>A Boolean indicating whether to send email reminders for this location (true) or not (false). The default is false.</td></tr><tr><td>WarningDays</td><td>An integer indicating the number of days before expiration to send the warning email.</td></tr><tr><td>Recipients</td><td>An object containing a list of strings with email addresses to which the email reminders should be sent.</td></tr></table></td></tr>
<tr><td>Dashboard</td><td>Body</td><td>Required. An array indicating the configuration for display on the dashboard. Dashboard details are:<table><tr><th>Value</th><th>Description</th></tr><tr><td>Show</td><td>Required. A Boolean indicating whether to show this revocation monitoring location on the Revocation Monitoring dashboard</td></tr></table></td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>(true) or not (false). The default is false.</td></tr>
<tr><td>WarningHours</td><td>Required*. An integer indicating the number of hours prior to expiration when the location begins to appear in a warning state on the dashboard.
WarningHours is required if Show is set to true and EndpointType is CRL.
WarningHours is not supported for EndpointType OCSP.
If the Days or Weeks value is selected in the Management Portal, it will be converted to hours when stored in the database.</td></tr>
</table>
</td></tr>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.18.6 POST Monitoring Resolve OSCP

The POST /Monitoring/ResolveOCSP method is used to resolve the given OCSP certificate authority. This method returns HTTP 200 OK on a success with details of the location.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
WorkflowManagement: *Modify*

Table 373: POST Monitoring Resolve OCSP Input Parameters

Name	In	Description
CertificateContents	Body	**Required***. A string indicating the certificate contents of a base-64 encoded PEM issued by the CA that you wish to resolve. One of either *CertificateContents* or *CertificateAuthorityId* is required, but not both.
CertificateAuthorityId	Body	**Required***. An integer indicating the Keyfactor Command reference ID of the CA in the database. Use the *GET /CertificateAuthority* method (see GET Certificate Authority on page 1008) to retrieve a list of all the CAs to determine the ID. One of either *CertificateContents* or *CertificateAuthorityId* is required, but not both.

Table 374: POST Monitoring Resolve OCSP Response Data

Name	Description
CertificateAuthorityId	An integer indicating the Keyfactor Command reference ID of the CA in the database.
AuthorityName	A string indicating the resolved certificate authority's name in X.500 format.
AuthorityNameId	A string indicating the hash of the certificate authority's name in hex format.
AuthorityKeyId	A string indicating the public key of the certificate authority's certificate.
SampleSerialNumber	A string indicating the serial number of the certificate authority's certificate.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.18.7 POST Monitoring Revocation Test

The POST /Monitoring/Revocation/Test method is used to test email alerts for a single configured revocation monitoring endpoint. This method returns HTTP 200 OK on a success with details about the email message generated for each alert.

Tip: Alerts are generated when a CRL is expired or in the warning period as defined by the number of days configured in the *Email Reminder* setting. For example, if you had a CRL that expired on June 30 and configured the email reminder period to 15 days before expiration, the warning status would begin for that CRL on June 15 and CRL alerts would be generated. A warning will also appear for any CRL or OCSP locations that produced an error or couldn't be resolved.

When alerts are tested or sent on a schedule, corresponding message are also written to the system event log on the server where the Keyfactor Command service runs. For testing, this is true regardless of the setting of the *SendAlerts* flag. Information is logged to the event log for both locations that are in a good state (e.g. CRL resolves and is not in a warning or expired state or response from OCSP) and locations that are in an error state (e.g. CRL resolves but is in the warning period or expired, CRL is expired, CRL or OCSP location does not resolve).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
WorkflowManagement: *Read*
WorkflowManagement: *Test*

Table 375: POST Monitoring Revocation Test Input Parameters

Name	In	Description
revocationMonitoringAlertTestRequest	Body	**Required**. An array containing information for the alert test. Alert test detail values are: **Name** / **Description** AlertId — **Required**. An integer indicating the reference ID of revocation monitoring alert to test. EvaluationDate — **Required**. A string indicating the evaluation date/time for the test, in UTC. You can use the date to simulate running the alerts a month from now instead of today, for example, or put in a date far in the future to be sure you pick up some expiring CRLs for testing purposes. SendAlerts — A Boolean indicating whether to send alert emails with the test (true) or not (false). The default is *false*. For example: `{ "EvaluationDate": "2022-08-31T20:51:33.528Z" "SendAlerts": true }`

Table 376: POST Monitoring Revocation Test Response Data

<table>
<tr><th>Parameter</th><th>Description</th></tr>
<tr><td>RevocationMonitoringAlerts</td><td>An object containing alert details resulting from the test. Revocation monitoring alert details are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Subject</td><td>A string indicating the email message subject for each alert. The content of this subject is not user configurable.</td></tr>
<tr><td>Message</td><td>A string indicating the email message that will be delivered for each alert. The content of this message is not user configurable.</td></tr>
<tr><td>Recipients</td><td>An object containing the recipient(s) for the alert.</td></tr>
</table></td></tr>
<tr><td>AlertBuildResult</td><td>A string indicating the outcome of the test (e.g. Success).</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.18.8 POST Monitoring Revocation Test All

The POST /Monitoring/Revocation/Test method is used to test email alerts for all configured revocation monitoring endpoints. Alerts are generated when a CRL is expired or in the warning period as defined by the number of days configured in the *Email Reminder* setting or when an OCSP endpoint is unreachable. For example, if you had a CRL that expired on June 30 and configured the email reminder period to 15 days before expiration, the warning status would begin for that CRL on June 15 and CRL alerts would be generated. This method returns HTTP 200 OK on a success with details about the email message generated for each alert.

Tip: Alerts are generated when a CRL is expired or in the warning period as defined by the number of days configured in the *Email Reminder* setting. For example, if you had a CRL that expired on June 30 and configured the email reminder period to 15 days before expiration, the warning status would begin for that CRL on June 15 and CRL alerts would be generated. A warning will also appear for any CRL or OCSP locations that produced an error or couldn't be resolved.
When alerts are tested or sent on a schedule, corresponding message are also written to the system event log on the server where the Keyfactor Command service runs. For testing, this is true regardless of the setting of the *SendAlerts* flag. Information is logged to the event log for both locations that are in a good state (e.g. CRL resolves and is not in a warning or expired state or response from OCSP) and locations that are in an error state (e.g. CRL resolves but is in the warning period or expired, CRL is expired, CRL or OCSP location does not resolve).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
WorkflowManagement: *Read*
WorkflowManagement: *Test*

Table 377: POST Monitoring Revocation Test All Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>revocationMonitoringAlertTestRequest</td><td>Body</td><td>Required. An array containing information for the alert test. Alert test detail values are:
<table><tr><th>Name</th><th>Description</th></tr><tr><td>EvaluationDate</td><td>Required. A string indicating the evaluation date/time for the test, in UTC.
You can use the date to simulate running the alerts a month from now instead of today, for example, or put in a date far in the future to be sure you pick up some expiring CRLs for testing purposes.</td></tr><tr><td>SendAlerts</td><td>A Boolean indicating whether to send alert emails with the test (true) or not (false). The default is false.</td></tr></table>For example:
<pre>{
   "EvaluationDate": "2022-08-31T20:51:33.528Z"
   "SendAlerts": true
}</pre></td></tr>
</table>

Table 378: POST Monitoring Revocation Test All Response Data

<table>
<tr><th>Parameter</th><th>Description</th></tr>
<tr><td>RevocationMonitoringAlerts</td><td>An object containing alert details resulting from the test. Revocation monitoring alert details are:<table><tr><th>Name</th><th>Description</th></tr><tr><td>Subject</td><td>A string indicating the email message subject for each alert. The content of this subject is not user configurable.</td></tr><tr><td>Message</td><td>A string indicating the email message that will be delivered for each alert. The content of this message is not user configurable.</td></tr><tr><td>Recipients</td><td>An object containing the recipient(s) for the alert.</td></tr></table></td></tr>
<tr><td>AlertBuildResult</td><td>A string indicating the outcome of the test (e.g. Success).</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.19 Orchestrator Jobs

The Orchestrator Jobs component of the Keyfactor API includes methods necessary to schedule orchestrator jobs and view the results of jobs.

Table 379: Orchestrator Jobs Endpoints

Endpoint	Method	Description	Link
/JobStatus/Data	GET	Retrieves the results of a custom job using the provided information.	GET Orchestrator Jobs Job Status Data on the next page
/JobHistory	GET	Returns the details of history records on orchestrator jobs, including in-process jobs.	GET Orchestrator Jobs Job History on page 1416
/ScheduledJobs	GET	Returns the details of active scheduled jobs, including in-process jobs.	GET Orchestrator Jobs Scheduled Jobs on page 1421
/Custom	POST	Schedules a custom job on the orchestrator using the provided information.	POST Orchestrator Jobs Custom on page 1425
/Reschedule	POST	Reschedules a failed orchestrator job.	POST Orchestrator Jobs Reschedule on page 1429

Endpoint	Method	Description	Link
/Unschedule	POST	Unschedules an active orchestrator job.	POST Orchestrator Jobs Unschedule on page 1431
/Acknowledge	POST	Sets the status of a failed orchestrator job to acknowledged.	POST Orchestrator Jobs Acknowledge on page 1432
/Custom/Bulk	POST	Schedules a custom job on multiple orchestrator using the provided information.	POST Orchestrator Jobs Reschedule on page 1429

3.2.19.1 GET Orchestrator Jobs Job Status Data

The GET /OrchestratorJobs/JobStatus/Data method is used to return the data generated from a completed custom orchestrator (a.k.a. agent) job for a given job ID. This method returns HTTP 200 OK on a success with up to 2 MB of data from the job results.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
AgentManagement: *Read*

Tip: This method is used to return the log results from a Fetch Logs job initiated for the Keyfactor Universal Orchestrator. When used to return results for a Fetch Logs job, the last 2 MB of data from the orchestrator's log file are returned as a string in the Data field.

Tip: If jobs for the Keyfactor Universal Orchestrator fail with messages similar to the following:

```
2021-08-05 10:47:23.1940
Keyfactor.Orchestrators.JobExecutors.OrchestratorJobExecutor [Debug] - Response
status code does not indicate success: 413 (Request Entity Too Large).

at System.Net.Http.HttpResponseMessage.EnsureSuccessStatusCode() in /_
/src/System.Net.Http/src/System/Net/Http/HttpResponseMessage.cs:line 172

at Keyfactor.Orchestrators.Services.HttpService.SendPostAsync[T](String uri, Object
requestData, Dictionary`2 headers) in F:\BuildAgents\Default1\_
work\24\s\src\OrchestratorServices\HttpService.cs:line 38
```

This indicates that the amount of data being returned on the job is greater than IIS on the Keyfactor Command server is configured to accept. You will need to make modifications to the IIS settings on your Keyfactor Command server to allow it to accept larger incoming pieces of content. See Fetch Logs on page 464 in the *Keyfactor Command Reference Guide* for more information.

Table 380: GET Orchestrator Jobs Job Status Data Input Parameters

Name	In	Description
jobHistoryId	Query	**Required**. The Keyfactor Command reference ID of the orchestrator job. Use the GET /OrchestratorJobs/JobHistory method (see GET Orchestrator Jobs Job History below) to retrieve a list of jobs to determine the job's history ID.

Table 381: GET Orchestrator Jobs Job Status Data Response Data

Name	Description
JobHistoryId	An integer indicate the Keyfactor Command reference ID used to track progress during orchestrator jobs.
Data	A string containing up to 2 MB of data returned from the custom job.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.19.2 GET Orchestrator Jobs Job History

The GET /OrchestratorJobs/JobHistory method is used to retrieve the status of an in progress or completed orchestrator (a.k.a. agent) job for a given job ID. This method returns HTTP 200 OK on a success with details of the requested orchestrator jobs.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
AgentManagement: *Read*

Table 382: GET Orchestrator Jobs Job History Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Job History Search Feature on page 472. The query fields supported for this endpoint are: • *AgentId* (The GUID of the orchestrator. Run GET Agents on page 727 to find the ID) • *Agent* (ClientMachine) • *JobId* • *Result* (Job result: 4-Failure, 3-Warning, 2-Success, 0-Unknown) • *Status* (Job status: 4-Acknowledged, 3-Completed, 2-InProcess, 1-Waiting, 0-Unknown, 5-CompletedWillRetry) • *JobType* (Management, Inventory, Discovery, SslDiscovery, Reenrollment, Monitoring, Sync, SSHSync) • *Message* • *OperationStart* (DateTime) • *ScheduleType* (Schedule: null (Immediately), I_(Interval), D_(Daily), W_(Weekly),M_(Monthly), O_(Once)) • *TargetPath*
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *JobHistoryId*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 383: GET Orchestrator Jobs Job History Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>JobHistoryId</td><td>An integer indicating the Keyfactor Command reference ID used to track progress during orchestrator jobs.</td></tr>
<tr><td>AgentMachine</td><td>A string indicating the name of the server on which the agent or orchestrator is installed. This is not necessarily the actual DNS name of the server; the orchestrator may have been installed using an alternative as a reference name.</td></tr>
<tr><td>JobId</td><td>A string indicating the Keyfactor Command reference GUID assigned to the job.</td></tr>
<tr><td>Schedule</td><td>The inventory schedule for the most recently run instance of the orchestrator job. Possible values are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Immediate</td><td>A Boolean that indicates a job scheduled to run immediately (true) or not (false).

Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as null.</td></tr>
<tr><td>Interval</td><td>A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Minutes</td><td>An integer indicating the number of minutes between each interval.</td></tr>
</table>
For example, every hour:
<pre>"Interval": {
   "Minutes": 60
}</pre></td></tr>
<tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time</td></tr>
</table></td></tr>
</table></td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, daily at 11:30 pm:
<pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre>
</td></tr>
<tr><td>Weekly</td><td>A dictionary that indicates a job scheduled to run on a specific day or days every week at the same time with the parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
<tr><td>Days</td><td>An array of values representing the days of the week on which to run the job. These can either be entered as integers (0 for Sunday, 1 for Monday, etc.) or as days of the week (e.g. "Sunday").</td></tr>
</table>
For example, every Monday, Wednesday and Friday at 5:30 pm:
<pre>"Weekly": {
   "Days": [
      "Monday",
      "Wednesday",
      "Friday"
   ],
   "Time": "2022-02-27T17:30:00Z"
}</pre>
</td></tr>
<tr><td>Monthly</td><td>A dictionary that indicates a job scheduled to run on a specific day or days every month at the same time with the parameters:</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
<tr><td>Day</td><td>The number of the day, in the month, to run the job.</td></tr>
</table>
For example, on the first of every month at 5:30 pm:
<pre>"Monthly": {
   "Day": 1
   "Time": "2022-02-27T17:30:00Z"
}</pre>
</td></tr>
<tr><td>ExactlyOnce</td><td>A dictionary that indicates a job scheduled to run at the time specified with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, exactly once at 11:45 am:
<pre>"ExactlyOnce": {
   "Time": "2022-02-27T11:45:00Z"
}</pre>
Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as ExactlyOnce. </td></tr>
</table>
</td></tr>
<tr><td>JobType</td><td>A string indicating the job type (e.g. IISInventory).</td></tr>
<tr><td>OperationStart</td><td>The time, in UTC, at which the orchestrator job started.</td></tr>
<tr><td>OperationEnd</td><td>The time, in UTC, at which the orchestrator job finished.</td></tr>
<tr><td>Message</td><td>A string providing the error message for the operation, if any.</td></tr>
<tr><td>Result</td><td>A string indicating the result of the orchestrator job. Possible values are:
Unknown</td></tr>
</table>

Name	Description
	• Success • Warning • Failure
Status	A string indicating the status of the orchestrator job. Possible values are: • Unknown • Waiting • In Process • Completed • Acknowledged • Completed Will Retry
StorePath	A string indicating the path to the certificate store on the target. The format for this path will vary depending on the certificate store type. For example, for a Java keystore, this will be a file path (e.g. /opt/myapp/store.jks), but for an F5 device, this will be a partition name on the device (e.g. Common). See Adding or Modifying a Certificate Store on page 363 in the *Keyfactor Command Reference Guide* for more information.
ClientMachine	A string indicating the name of the client machine. The value for this will vary depending on the certificate store type. For example, for a Java keystore or an F5 device, it is the hostname of the machine on which the store is located, but for an Amazon Web Services store, it is the FQDN of the Keyfactor Command Windows Orchestrator. See Adding or Modifying a Certificate Store on page 363 in the *Keyfactor Command Reference Guide* for more information.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.19.3 GET Orchestrator Jobs Scheduled Jobs

The GET /OrchestratorJobs/ScheduledJobs method is used to retrieve orchestrator (a.k.a. agent) jobs that have active schedules. This includes jobs with ongoing schedules, such as inventory jobs that run periodically, and jobs that have been scheduled but have not yet been completed, such as management or discovery jobs. Both jobs that have not yet started and in-progress jobs are returned by this method. This method returns HTTP 200 OK on a success with details of the scheduled orchestrator jobs.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
AgentManagement: *Read*

Table 384: GET Orchestrator Jobs Scheduled Jobs Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Job History Search Feature on page 472. The query fields supported for this endpoint are: • *AgentId* (The GUID of the orchestrator. Run GET Agents on page 727 to find the ID) • *Agent Machine* (ClientMachine) • *AgentPlatform* (Platform types: 0-Unknown, 1-.NET, 2-Java, 3-Mac, 4-Android, 5-Native, 6-Bash, 7-Universal Orchestrator) • *JobType* (Management, Inventory, Discovery, SslDiscovery, Reenrollment, Monitoring, Sync, SSHSync) • *AgentType* *Use -contains comparison (Capabilities in GET Agents on page 727) • *Requested* (DateTime) • *ScheduleType* (Schedule: null (Immediately), I_(Interval), D_(Daily), W_(Weekly),M_(Monthly), O_(Once)) • *TargetPath*
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *Requested*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 385: GET Orchestrator Jobs Scheduled Jobs Response Data

Name	Description
Id	A string indicating the Keyfactor Command reference GUID assigned to the job.
ClientMachine	A string indicating the name of the client machine. The value for this will vary depending on the certificate store type. For example, for a Java keystore or an F5 device, it is the hostname of the machine on which the store is located, but for an Amazon Web Services store, it is the FQDN of the Keyfactor Command Windows Orchestrator. See Adding or Modifying a Certificate Store on page 363 in the *Keyfactor Command Reference Guide* for more information.
Target	A string indicating the server name and path to the certificate store on the target (e.g. appsr-vr162.keyexample.com - /opt/app/store.cer). The server name included in the *Target* is the value from the *ClientMachine*. The format for the path will vary depending on the certificate store type. For example, for a Java keystore, this will be a file path (e.g. /opt/myapp/store.jks), but for an F5 device, this will be a partition name on the device (e.g. Common). Some types of jobs (e.g. discovery) have no path. See Adding or Modifying a Certificate Store on page 363 in the *Keyfactor Command Reference Guide* for more information.

Name	Description
Schedule	

Name	Description
Requested	The time, in UTC, at which the orchestrator job was initiated and added to the job queue.
JobType	A string indicating the job type (e.g. IISInventory).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.19.4 POST Orchestrator Jobs Custom

The POST /OrchestratorJobs/Custom method is used to schedule a job with a custom job type on an orchestrator. This method returns HTTP 200 OK on a success with the GUID for the scheduled job.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: AgentManagement: *Modify*

Tip: Data returned from a custom job once the job completes (e.g. a FetchLogs job) is stored in the Keyfactor Command database. To retrieve the data, use the *GET /OrchestratorJobs/JobHistory* method (see GET Orchestrator Jobs Job History on page 1416) to determine the *JobHistoryId* of the completed job and then use the *GET /OrchestratorJobs/JobStatus/Data* method (see GET Orchestrator Jobs Job Status Data on page 1415) to retrieve the data.

Table 386: POST Orchestrator Jobs Custom Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>AgentId</td><td>Body</td><td>Required. A string indicating the Keyfactor Command reference GUID of the orchestrator that will execute this job.
To schedule a Fetch Logs job, use the GET /Agents method (see GET Agents on page 727) with a query of Status -eq 2 and Capabilities -contains "LOGS" to retrieve a list of your approved orchestrators with the LOGS capability to determine the ID of the orchestrator for which you want to retrieve logs.
To schedule a job using your custom job type, use the GET /Agents method (see GET Agents on page 727) with a query of Status -eq 2 to retrieve a list of your approved orchestrators to determine the ID of the orchestrator for which you want to schedule a custom job with your custom job type.</td></tr>
<tr><td>JobTypeName</td><td>Body</td><td>Required. A string indicating the reference name for the custom job type for the job.
Use the GET /JobTypes/Custom method (see GET Custom Job Types on page 1281) to retrieve a list of your defined custom job types to determine the job type name to use.</td></tr>
<tr><td>Schedule</td><td>Body</td><td>An object containing the schedule for the custom job. The following schedule types are supported:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
<tr><td>Immediate</td><td>A Boolean that indicates a job scheduled to run immediately (true) or not (false).
Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as null.</td></tr>
<tr><td>Weekly</td><td>A dictionary that indicates a job scheduled to run on a specific day or days every week at the same time with the parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table></td></tr>
</table></td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Days</td><td>An array of values representing the days of the week on which to run the job. These can either be entered as integers (0 for Sunday, 1 for Monday, etc.) or as days of the week (e.g. "Sunday").</td></tr>
</table>
For example, every Monday, Wednesday and Friday at 5:30 pm:
<pre>"Weekly": {
   "Days": [
      "Monday",
      "Wednesday",
      "Friday"
   ],
   "Time": "2022-02-27T17:30:00Z"
}</pre>
</td></tr>
<tr><td>Monthly</td><td>A dictionary that indicates a job scheduled to run on a specific day or days every month at the same time with the parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
<tr><td>Day</td><td>The number of the day, in the month, to run the job.</td></tr>
</table>
For example, on the first of every month at 5:30 pm:
<pre>"Monthly": {
   "Day": 1
   "Time": "2022-02-27T17:30:00Z"
}</pre>
</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>ExactlyOnce</td><td>A dictionary that indicates a job scheduled to run at the time specified with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, exactly once at 11:45 am:
<pre>"ExactlyOnce": {
   "Time": "2022-02-27T11:45:00Z"
}</pre>

Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as ExactlyOnce.</td></tr>
</table>

Note: Although the Swagger Example Value may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint.

The default is Immediate.</td></tr>
<tr><td>JobFields</td><td>Body</td><td>An array of key/value pairs that set the values for any optional job fields configured for the custom job type. The key is the field name and the value is the value for the field.

For example:
<pre>"JobFields": {
   "Favorite Type of Pet": "Rat",
   "Mother's Birthday": "1952-05-21"
}</pre>

Note: If a job field has been configured with a default value and you wish to accept the default value, the field does not need to be submitted along with the POST /OrchestratorJobs/Custom request. The default value will be set automatically by Keyfactor Command. Submitting a value overrides the default value.</td></tr>
</table>

Name	In	Description
		Use the *GET /JobTypes/Custom* method (see GET Custom Job Types on page 1281) to retrieve a list of your defined custom job types to determine the job fields defined for the job type. **Tip:** The built-in Fetch Logs job does not have any optional job fields.

Table 387: POST Orchestrator Jobs Custom Response Data

Name	Description
JobId	A string indicating the Keyfactor Command reference GUID for the job.
OrchestratorId	A string indicating the Keyfactor Command reference GUID of the orchestrator that will execute this job.
JobTypeName	A string indicating the reference name for the custom job type for the job.
Schedule	An object containing the schedule for the custom job.
JobFields	An array of key/value pairs that set the values for any optional job fields configured for the custom job type.
RequestTimestmap	The date, in UTC, when the custom job was submitted.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.19.5 POST Orchestrator Jobs Reschedule

The POST /OrchestratorJobs/Reschedule method is used to reschedule a failed orchestrator job to retry. Jobs must have a result of Failed and a status of Completed or Acknowledged to be eligible for rescheduling. This endpoint returns 204 with no content upon success.

Only select types of jobs are eligible for rescheduling, including:

- Certificate Store Management
- Reenrollment
- Mac Auto-enrollment
- JKS, PEM and F5 Certificate Store Discovery
- SSH Synchronization
- Custom Jobs scheduled to run Weekly or Monthly

The following types of jobs cannot be rescheduled with this method:

- Certificate Store Inventory
  Change the inventory schedule on certificate stores using POST /CertificateStores/Schedule (see POST Certificate Stores Schedule on page 1198).
- Custom Jobs scheduled to run Immediately or Exactly Once
  A new custom job should be scheduled after the problem is resolved using POST /OrchestratorJobs/Custom (see POST Orchestrator Jobs Custom on page 1425).
- Fetch Logs
  A new fetch logs job should be scheduled after the problem is resolved using POST /OrchestratorJobs/Custom (see POST Orchestrator Jobs Custom on page 1425).
- SSL Discovery and Monitoring
  Change the schedule on these using PUT /SSL/Networks (see PUT SSL Networks on page 1862).
- CA Synchronization for Remote CAs Managed with the Keyfactor Universal Orchestrator or Keyfactor Windows Orchestrator
  Change the schedule on these using PUT /CertificateAuthority (see PUT Certificate Authority on page 1046).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
AgentManagement: *Modify*
CertificateStoreManagement: *Schedule*

The required permissions will vary depending on the job type being rescheduled. The permissions shown above are appropriate for a certificate store management job.

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Tip: Be sure to resolve the problem that caused the job to fail before rescheduling it.

Table 388: POST Orchestrator Jobs Reschedule Input Parameters

Name	In	Description
JobAuditIds	Body	**Required***. An array of integers indicating the job IDs of the failed jobs that should be scheduled to retry. Use the *GET /OrchestratorJobs/JobHistory* method (see GET Orchestrator Jobs Job History on page 1416) with a query similar to the following to retrieve a list of all orchestrator jobs potentially eligible for rescheduling: `JobType -ne "Inventory" AND Result -eq "4" AND (Status -eq "4" OR Status -eq "3")` Either a list of one or more *JobAuditIds* or a *Query* is **required**, but not both.
Query	Body	**Required***. A string containing a query to identify the jobs to reschedule (e.g. field1 -eq value1 AND field2 -gt value2). Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search drop-downs for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide* Job History Search Feature on page 472 section. Either a list of one or more *JobAuditIds* or a *Query* is **required**, but not both.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.19.6 POST Orchestrator Jobs Unschedule

The POST /OrchestratorJobs/Unschedule method is used to unschedule a scheduled orchestrator job. This endpoint returns 204 with no content upon success.

Only select types of jobs are eligible for unscheduling, including:

- Certificate Store Discovery and Management
- Reenrollment
- Mac Auto-enrollment
- Fetch Logs
- Custom Jobs

The following types of jobs cannot be unscheduled with this method:

- Certificate Store Inventory
  Change the inventory schedule on certificate stores using POST /CertificateStores/Schedule (see POST Certificate Stores Schedule on page 1198).
- SSH Synchronization
  Change the schedule on these using PUT /SSH/ServerGroups (see PUT SSH Server Groups on page 1743).

- SSL Discovery and Monitoring
  Change the schedule on these using PUT /SSL/Networks (see PUT SSL Networks on page 1862).
- CA Synchronization for Remote CAs Managed with the Keyfactor Universal Orchestrator or Keyfactor Windows Orchestrator
  Change the schedule on these using PUT /CertificateAuthority (see PUT Certificate Authority on page 1046).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
AgentManagement: *Modify*
CertificateStoreManagement: *Schedule*

The required permissions will vary depending on the job type being unscheduled. The permissions shown above are appropriate for a certificate store management job.

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions on page 591 in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

Table 389: POST Orchestrator Jobs Unschedule Input Parameters

Name	In	Description
JobIds	Body	**Required***. An array of GUIDs indicating the job IDs of the jobs that should be unscheduled. Use the *GET /OrchestratorJobs/ScheduledJobs* method (see GET Orchestrator Jobs Scheduled Jobs on page 1421) with a query similar to the following to retrieve a list of all orchestrator jobs potentially eligible for unscheduling: `JobType -notcontains "SslDiscovery" AND JobType -notcontains "Monitoring" AND JobType -notcontains "Sync" AND JobType -notcontains "SSHSync" AND JobType -notcontains "Inventory"` Either a list of one or more *JobIds* or a *Query* is **required**, but not both.
Query	Body	**Required***. A string containing a query to identify the jobs to unschedule (e.g. field1 -eq value1 AND field2 -gt value2). Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide* Orchestrator Scheduled Job Search Feature on page 468 section. Either a list of one or more *JobIds* or a *Query* is **required**, but not both.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.19.7 POST Orchestrator Jobs Acknowledge

The POST /OrchestratorJobs/Acknowledge method is used to set an orchestrator job to a status of acknowledged. Jobs must have a result of Failed or Warning and a status of Completed or CompletedWillRetry to be eligible for

acknowledgment. Jobs that are in process or that have completed successfully cannot be set to a status of acknowledged. Setting a job to a status of acknowledged removes it from the count on the job history tab in the Keyfactor Command Management Portal (if the job falls within the count period defined by the *Job Failures and Warnings Age Out (days)* application setting—see Application Settings: Agents Tab on page 565 in the *Keyfactor Command Reference Guide*). This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
AgentManagement: *Modify*

Table 390: POST Orchestrator Jobs Acknowledge Input Parameters

Name	In	Description
JobAuditIds	Body	**Required***. An array of integers indicating the job IDs of the jobs that should be set to a status of acknowledged. Use the *GET /OrchestratorJobs/JobHistory* method (see GET Orchestrator Jobs Job History on page 1416) with a query similar to the following to retrieve a list of all orchestrator jobs potentially eligible for acknowledgement: `(Result -eq "4" OR Result -eq "3") AND (Status -eq "3" OR Status -eq "5")` Either a list of one or more *JobAuditIds* or a *Query* is **required**, but not both.
Query	Body	**Required***. A string containing a query to identify the jobs to acknowledge (e.g. field1 -eq value1 AND field2 -gt value2). Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search drop-downs for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide* Job History Search Feature on page 472 section. Either a list of one or more *JobAuditIds* or a *Query* is **required**, but not both.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.19.8 POST Orchestrator Jobs Custom Bulk

The POST /OrchestratorJobs/Custom/Bulk method is used to schedule a job with a specified custom job type on multiple orchestrators at once. This method returns HTTP 200 OK on a success with the GUIDs for the scheduled jobs.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
AgentManagement: *Modify*

Tip: Data returned from a custom job once the job completes (e.g. a FetchLogs job) is stored in the Keyfactor Command database. To retrieve the data, use the *GET /OrchestratorJobs/JobHistory* method (see GET Orchestrator Jobs Job History on page 1416) to determine the *JobHistoryId* of the completed job and then use the *GET /OrchestratorJobs/JobStatus/Data* method (see GET Orchestrator Jobs Job Status Data on page 1415) to retrieve the data.

Table 391: POST Orchestrator Jobs Custom Bulk Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>Orches-tratorIds</td><td>Body</td><td>Required. A string indicating the Keyfactor Command referenced GUIDs of the orchestrators what will execute the jobs.
To schedule a Fetch Logs job, use the GET /Agents method (see GET Agents on page 727) with a query of Status -eq 2 and Capabilities -contains "LOGS" to retrieve a list of your approved orchestrators with the LOGS capability to determine the ID of the orchestrators for which you want to retrieve logs.
To schedule a job using your custom job type, use the GET /Agents method (see GET Agents on page 727) with a query of Status -eq 2 to retrieve a list of your approved orchestrators to determine the ID of the orchestrators for which you want to schedule a custom job with your custom job type.</td></tr>
<tr><td>JobTypeName</td><td>Body</td><td>Required. A string indicating the reference name for the custom job type for the job. A single bulk operation can only execute one job type.
Use the GET /JobTypes/Custom method (see GET Custom Job Types on page 1281) to retrieve a list of your defined custom job types to determine the job type name to use.</td></tr>
<tr><td>Schedule</td><td>Body</td><td>An object containing the schedule for the custom job. The following schedule types are supported:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
<tr><td>Immediate</td><td>A Boolean that indicates a job scheduled to run immediately (true) or not (false).
Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as null.</td></tr>
<tr><td>Interval</td><td>A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Minutes</td><td>An integer indicating the number of minutes between each interval.</td></tr>
</table>
For example, every hour:</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td><pre>"Interval": {
   "Minutes": 60
}</pre></td></tr>
<tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:
<table><tr><th>Name</th><th>Description</th></tr><tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr></table>For example, daily at 11:30 pm:
<pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre></td></tr>
<tr><td>Weekly</td><td>A dictionary that indicates a job scheduled to run on a specific day or days every week at the same time with the parameters:
<table><tr><th>Name</th><th>Description</th></tr><tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr><tr><td>Days</td><td>An array of values representing the days of the week on which to run the job. These can either be entered as integers (0 for Sunday, 1 for Monday, etc.) or as days of the week (e.g. "Sunday").</td></tr></table>For example, every Monday, Wednesday and Friday at 5:30 pm:
<pre>"Weekly": {
   "Days": [
      "Monday",</pre></td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<pre>
      "Wednesday",
      "Friday"
   ],
   "Time": "2022-02-27T17:30:00Z"
}
</pre>
</td></tr>
<tr><td>Monthly</td><td>A dictionary that indicates a job scheduled to run on a specific day or days every month at the same time with the parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
<tr><td>Day</td><td>The number of the day, in the month, to run the job.</td></tr>
</table>
For example, on the first of every month at 5:30 pm:
<pre>
"Monthly": {
   "Day": 1
   "Time": "2022-02-27T17:30:00Z"
}
</pre>
</td></tr>
<tr><td>ExactlyOnce</td><td>A dictionary that indicates a job scheduled to run at the time specified with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, exactly once at 11:45 am:
<pre>
"ExactlyOnce": {
   "Time": "2022-02-27T11:45:00Z"
}
</pre>
Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as ExactlyOnce.
</td></tr>
</table>
</td></tr>
</table>

Name	In	Description
		Note: Although the Swagger *Example Value* may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint. The default is *Immediate*.

JobFields	Body	An array of key/value pairs that set the values for any optional job fields configured for the custom job type. The *key* is the field name and the *value* is the value for the field.
		For example:
		
		`"JobFields": {`
		`"Favorite Type of Pet": "Rat",`
		`"Mother's Birthday": "1952-05-21"`
		`}`
		
		Note: If a job field has been configured with a default value and you wish to accept the default value, the field does not need to be submitted along with the POST /OrchestratorJobs/Custom request. The default value will be set automatically by Keyfactor Command. Submitting a value overrides the default value.
		
		Use the *GET /JobTypes/Custom* method (see GET Custom Job Types on page 1281) to retrieve a list of your defined custom job types to determine the job fields defined for the job type.
		
		Tip: The built-in Fetch Logs job does not have any optional job fields.

Table 392: POST Orchestrator Jobs Custom Bulk Response Data

Name	Description
OrchestratorJobPairs	An array containing identifying information for each orchestrator on which the job will be run. Orchestrator job pair parameters include: **Value** / **Description** JobId — A string indicating the Keyfactor Command reference GUID for the job. OrchestratorId — A string indicating the Keyfactor Command reference GUID of the orchestrator that will execute this job.
JobTypeName	A string indicating the reference name for the custom job type for the job.
Schedule	An object containing the schedule for the custom job.
JobFields	An array of key/value pairs that set the values for any optional job fields configured for the custom job type.
RequestTimestmap	The date, in UTC, when the custom job was submitted.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.20 PAM Providers

Privileged Access Management (PAM) functionality in Keyfactor Web APIs allows for configuration of third party PAM providers to secure certificate stores. In the current release, both CyberArk and Delinea (formerly Thycotic) are supported. The PAM component of the Keyfactor API includes methods necessary to programmatically create, delete, edit, and list PAM Providers.

Table 393: PamProviders Endpoints

Endpoint	Method	Description	Link
/{id}	DELETE	Deletes a PAM provider.	DELETE PAM Providers ID on the next page
/{id}	GET	Returns information for the specified PAM provider.	GET PAM Providers ID on the next page
/Types	GET	Returns a list of all available PAM provider types.	GET PAM Providers Types on page 1449

Endpoint	Method	Description	Link
/Types	POST	Creates a new PAM provider type.	POST PAM Providers Types on page 1452
/	GET	Returns a list of all the configured PAM providers.	GET PAM Providers on page 1455
/	POST	Creates a new PAM provider.	POST PAM Providers on page 1464
/	PUT	Updates a PAM provider.	PUT PAM Providers on page 1480

3.2.20.1 DELETE PAM Providers ID

The DELETE /PamProviders/{id} method is used to delete a PAM provider by ID. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
PrivilegedAccessManagement: *Modify*

Table 394: DELETE PamProviders {id} Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID for the PAM provider to be deleted. Use the *GET /PamProviders* method (see GET PAM Providers on page 1455) to retrieve a list of all the PAM providers to determine the PAM provider's ID.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.20.2 GET PAM Providers ID

The GET /PamProviders/{id} method is used to return a PAM provider by ID. This method returns HTTP 200 OK on a success with details about the specified PAM provider.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
PrivilegedAccessManagement: *Read*
SystemSettings: *Read*

Table 395: GET PamProviders {id} Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID of the PAM provider to retrieve. Use the *GET /PAM/Providers* method (see GET PAM Providers on page 1455) to retrieve a list of all the PAM providers to determine the provider's ID.

Table 396: GET PamProviders {id} Response Data

Name	Description
ID	An integer indicating the Keyfactor Command reference ID for the PAM provider. This ID is automatically set by Keyfactor Command.
Name	A string indicating the name of the PAM provider. This name used to identify the PAM provider throughout Keyfactor.
Area	An integer indicating the area of Keyfactor Command the provider is used for. PAM providers generally have a value of 1, indicating they are used for certificate stores.
ProviderType	An array containing details about the provider type for the provider. Provider type details include:

Value	Description
Id	A string indicating the Keyfactor Command reference GUID for the provider type.
Name	A string indicating the name of the provider type.
ProviderTypeParams	An array of parameters that the provider type uses for data input in Keyfactor Command when creating new PAM provider and certificate store records. Provider type parameters values include:

Value	Description
Id	An integer indicating the Keyfactor Command reference ID for the PAM provider type parameter.
Name	A string indicating the internal name for the PAM provider type parameter.
DisplayName	A string indicating the display name for the PAM provider type parameter. For parameters with an *InstanceLevel* of *False*, this name appears on the PAM provider dialog for the parameter when a user creates a new PAM provider. For parameters with an *InstanceLevel* of *True*, this name appears on the Server dialog for the parameter when a user creates a new PAM provider.

Name	Description
	Value / **Description**

Value	Description
DataType	An integer indicating the data type for the parameter. Possible values are: • 1 = String • 2 = Secret
InstanceLevel	A Boolean that sets whether the parameter is used to define the underlying PAM provider (False) or a field that needs to be set to a value when configuring a certificate store to use the PAM provider (True).  **Example:** For CyberArk when defining a PAM provider, you configure two CyberArk-specific fields: • PrivateArk Safe: The name of the safe in CyberArk containing the certificate store password you wish to use. • Application ID: The name of the application created in CyberArk for use with Keyfactor Command. Because these fields are configured on the PAM provider definition, they appear as InstanceLevel=False like so: `{ "Id": 1, "Name": "Safe", "DisplayName": "Priv-ateArk Safe", "DataType": 1, "InstanceLevel": false,`

Name	Description
	Value / **Description**

```
   "ProviderType": null
},
{
   "Id": 4,
   "Name": "AppId",
   "DisplayName": "Applic-
ation ID",
   "DataType": 1,
   "InstanceLevel": false,
   "ProviderType": null
}
```

When you configure a certificate store to use CyberArk as a credential provider, you enter the name of the folder in the CyberArk safe where the protected object is stored and you enter the name of the projected object in the CyberArk safe containing the username or password used to access the certificate store. Because these fields are configured on the certificate store level, they appear as InstanceLevel=True like so:

```
{
   "Id": 2,
   "Name": "Folder",
   "DisplayName": "Priv-
ateArk Folder Name",
   "DataType": 1,
   "InstanceLevel": true,
   "ProviderType": null
},
{
   "Id": 3,
   "Name": "Object",
```

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td> 
<pre>
   "DisplayName": "Priv-
ateArk Protected Password
Name",
   "DataType": 1,
   "InstanceLevel": true,
   "ProviderType": null
}
</pre>
In both cases, the values for the fields (e.g. the actual name of the object in CyberArk where the password is stored) are stored in the ProviderTypeParamValues array.</td></tr>
<tr><td>ProviderType</td><td>An array containing details for the provider type. Provider type parameters include:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>Id</td><td>The Keyfactor Command reference GUID for the PAM provider type parameter.</td></tr>
<tr><td>Name</td><td>A string indicating the internal name for the PAM provider type parameter.</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

</td></tr>
</table>
</td></tr>
<tr><td>Provider-TypeParamValues</td><td>An array containing the values for the provider types specified by ProviderTypeParams. Provider type parameter values include:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID for the PAM provider type parameter.</td></tr>
<tr><td>Value</td><td>A string indicating the value set for the parameter (e.g. the name of the CyberArk folder where the protected object that stores the user-name or password resides).</td></tr>
<tr><td>InstanceId</td><td>An integer indicating the Keyfactor Command reference ID for the provider. If you are attaching to something with an integer Id, this will be used.</td></tr>
<tr><td>InstanceGuid</td><td>A string indicating the Keyfactor Command reference GUID for the provider. If you are attaching to something with a GUID ID, this will be used.</td></tr>
<tr><td>Provider</td><td>An array containing information about the provider.</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>Provider-TypeParams</td><td>An array of parameters that the provider type uses for data input in Keyfactor Command when creating new PAM provider and certificate store records. Provider type parameters values include:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID for the PAM provider type parameter.</td></tr>
<tr><td>Name</td><td>A string indicating the internal name for the PAM provider type parameter.</td></tr>
<tr><td>DisplayName</td><td>A string indicating the display name for the PAM provider type parameter. For parameters with an InstanceLevel of False, this name appears on the PAM provider dialog for the parameter when a user creates a new PAM provider. For parameters with an InstanceLevel of True, this name appears on the Server dialog for the parameter when a user creates a new PAM provider.</td></tr>
<tr><td>DataType</td><td>An integer indicating the data type for the parameter. Possible values are:
1 = String
2 = Secret</td></tr>
<tr><td>InstanceLevel</td><td>A Boolean that sets whether the parameter is used to define the underlying PAM provider (False) or a field that needs to be set to a value when configuring a certificate store to use the PAM provider (True).
See example, above.</td></tr>
<tr><td>ProviderType</td><td>An array containing details for the provider type. Provider type parameters include:</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>Id</td><td>The Keyfactor Command reference GUID for the PAM provider type parameter.</td></tr>
<tr><td>Name</td><td>A string indicating the internal name for the PAM provider type parameter.</td></tr>
<tr><td>ProviderTypeParams</td><td>An array of parameters that the provider type uses for data input in Keyfactor Command when creating new PAM provider and certificate store records.</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>
</td></tr>
<tr><td>SecureAreaId</td><td>An integer indicating the Keyfactor Command reference ID for the certificate store container the PAM provider is associated with, if any.
You can create a single PAM provider for each provider type (e.g. CyberArk), however, if you have opted to organize your certificate stores into containers, you will need to create multiple providers to match your container organization structure. The container field in the PAM provider definition is not required, but if one is supplied when creating a PAM provider, the PAM provider can only be used with certificate stores in the matching container. Likewise, a PAM provider defined with no container would be available for selection when setting pass-</td></tr>
</table>

Name	Description
	words for any certificate store that also did not specify a container. A PAM provider configured in this way could be used across a variety of certificate stores (e.g. both JKS and F5) as long as they were not in containers.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.20.3 GET PAM Providers Types

The GET /PamProviders/Types method returns a list of all the PAM provider types that have been configured in Keyfactor Command. This method returns HTTP 200 OK on a success with details about each PAM provider type. This method has no input parameters.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
PrivilegedAccessManagement: *Read*
SystemSettings: *Read*

Table 397: GET PamProviders Types Response Data

Name	Description
Id	A string containing the Keyfactor Command reference GUID for the PAM provider type.

	<pre>Protected Password Name",
	"DataType": 1,
	"InstanceLevel": true
	"ProviderType": null
	}</pre>
	In both cases, the *values* for the fields (e.g. the actual name of the object in CyberArk where the password is stored) are stored in the *ProviderTypeParamValues* array.</td></tr></table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon () at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.20.5 GET PAM Providers

The GET /PamProviders method returns a list of all the PAM providers that have been configured in Keyfactor Command. This method returns HTTP 200 OK on a success with details about each PAM provider.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
PrivilegedAccessManagement: *Read*
SystemSettings: *Read*

Table 399: GET PamProviders Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Certificate Search Page on page 31. The query fields supported for this endpoint are: • *Area* • *Name* • *ProviderType* • *SecuredAreaId*
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *Name*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 400: GET PamProviders Response Data

Name	Description
ID	An integer indicating the Keyfactor Command reference ID for the PAM provider. This ID is automatically set by Keyfactor Command.
Name	A string indicating the name of the PAM provider. This name used to identify the PAM provider throughout Keyfactor.
Area	An integer indicating the area of Keyfactor Command the provider is used for. PAM providers generally have a value of 1, indicating they are used for certificate stores.
ProviderType	An array containing details about the provider type for the provider. Provider type details include:

Value	Description
Id	A string indicating the Keyfactor Command reference GUID for the provider type.
Name	A string indicating the name of the provider type.
ProviderTypeParams	An array of parameters that the provider type uses for data input in Keyfactor Command when creating new PAM provider and certificate store records. Provider type parameters values include:

Value	Description
Id	An integer indicating the Keyfactor Command reference ID for the PAM provider type parameter.
Name	A string indicating the internal name for the PAM provider type parameter.
DisplayName	A string indicating the display name for the PAM provider type parameter. For parameters with an *InstanceLevel* of *False*, this name appears on the PAM provider dialog for the parameter when a user creates a new PAM provider. For parameters with an *InstanceLevel* of *True*, this name appears on the Server dialog for the parameter when a user creates a new PAM provider.

Name	Description

	<table><tr><th>Value</th><th>Description</th></tr><tr><td></td><td><table><tr><th>Value</th><th>Description</th></tr><tr><td>DataType</td><td>An integer indicating the data type for the parameter. </td></tr>
<tr><td>SecureAreaId</td><td>An integer indicating the Keyfactor Command reference ID for the certificate store container the PAM provider is associated with, if any.
You can create a single PAM provider for each provider type (e.g. CyberArk), however, if you have opted to organize your certificate stores into containers, you will need to create multiple providers to match your container organization structure. The container field in the PAM provider definition is not required, but if one is supplied when creating a PAM provider, the PAM provider can only be used with certificate stores in the matching container. Likewise, a PAM provider defined with no container would be available for selection when setting pass-</td></tr>
</table>

Name	Description
	words for any certificate store that also did not specify a container. A PAM provider configured in this way could be used across a variety of certificate stores (e.g. both JKS and F5) as long as they were not in containers.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.20.6 POST PAM Providers

The POST /PamProviders method creates a new PAM provider. This method returns HTTP 200 OK on a success with details for the new provider.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateStoreManagement: *Modify*
PrivilegedAccessManagement: *Modify*
SystemSettings: *Read*

Table 401: POST PamProviders Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>Name</td><td>Body</td><td>Required. A string indicating the name of the PAM provider. This name used to identify the PAM provider throughout Keyfactor.</td></tr>
<tr><td>Area</td><td>Body</td><td>An integer indicating the area of Keyfactor Command the provider is used for. PAM providers generally have a value of 1, indicating they are used for certificate stores.</td></tr>
<tr><td>ProviderType</td><td>Body</td><td>An array containing details about the provider type for the provider. Provider type details include:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>Id</td><td>A string indicating the Keyfactor Command reference GUID for the provider type.</td></tr>
<tr><td>Name</td><td>A string indicating the name of the provider type.</td></tr>
<tr><td>Provider-TypeParams</td><td>An array of parameters that the provider type uses for data input in Keyfactor Command when creating new PAM provider and certificate store records. Provider type parameters values include:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID for the PAM provider type parameter.</td></tr>
<tr><td>Name</td><td>A string indicating the internal name for the PAM provider type parameter.</td></tr>
<tr><td>DisplayNam-e</td><td>A string indicating the display name for the PAM provider type parameter. For parameters with an InstanceLevel of False, this name appears on the PAM provider dialog for the parameter when a user creates a new PAM provider. For parameters with an InstanceLevel of True, this name appears on the Server dialog for the parameter when a user creates a new PAM provider.</td></tr>
</table></td></tr>
</table></td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>DataType</td><td>An integer indicating the data type for the parameter. Possible values are:
1 = String
2 = Secret</td></tr>
<tr><td>InstanceLevel</td><td>A Boolean that sets whether the parameter is used to define the underlying PAM provider (False) or a field that needs to be set to a value when configuring a certificate store to use the PAM provider (True).

  Example: For CyberArk when defining a PAM provider, you configure two CyberArk-specific fields:
PrivateArk Safe: The name of the safe in CyberArk containing the certificate store password you wish to use.
Application ID: The name of the application created in CyberArk for use with Keyfactor Command.
Because these fields are configured on the PAM provider definition, they appear as InstanceLevel=False like so:

<pre>{
   "Id": 1,
   "Name": "Safe",
   "DisplayName":</pre></td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Name	In	Description

		Value / **Description**
		
		Value / **Description**
		
		"PrivateArk Safe",
		"DataType": 1,
		"InstanceLevel":
		false,
		"ProviderType":
		null
		},
		{
		"Id": 4,
		"Name": "AppId",
		"DisplayName":
		"Application ID",
		"DataType": 1,
		"InstanceLevel":
		false,
		"ProviderType":
		null
		}
		
		When you configure a certificate store to use CyberArk as a credential provider, you enter the name of the folder in the CyberArk safe where the protected object is stored and you enter the name of the projected object in the CyberArk safe containing the username or password used to access the certificate store. Because these fields are configured on the certificate store level, they appear as InstanceLevel=True like so:
		
		{
		"Id": 2,

Table 402: POST PamProviders Response Data

Name	Description
ID	An integer indicating the Keyfactor Command reference ID for the PAM provider. This ID is automatically set by Keyfactor Command.
Name	A string indicating the name of the PAM provider. This name used to identify the PAM provider throughout Keyfactor.
Area	An integer indicating the area of Keyfactor Command the provider is used for. PAM providers generally have a value of 1, indicating they are used for certificate stores.
ProviderType	An array containing details about the provider type for the provider. Provider type details include:

Value	Description
Id	A string indicating the Keyfactor Command reference GUID for the provider type.
Name	A string indicating the name of the provider type.
ProviderTypeParams	An array of parameters that the provider type uses for data input in Keyfactor Command when creating new PAM provider and certificate store records. Provider type parameters values include:

Value	Description
Id	An integer indicating the Keyfactor Command reference ID for the PAM provider type parameter.
Name	A string indicating the internal name for the PAM provider type parameter.
DisplayName	A string indicating the display name for the PAM provider type parameter. For parameters with an *InstanceLevel* of *False*, this name appears on the PAM provider dialog for the parameter when a user creates a new PAM provider. For parameters with an *InstanceLevel* of *True*, this name appears on the Server dialog for the parameter when a user creates a new PAM provider.

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>DataType</td><td>An integer indicating the data type for the parameter. Possible values are:
1 = String
2 = Secret</td></tr>
<tr><td>InstanceLevel</td><td>A Boolean that sets whether the parameter is used to define the underlying PAM provider (False) or a field that needs to be set to a value when configuring a certificate store to use the PAM provider (True).

  Example: For CyberArk when defining a PAM provider, you configure two CyberArk-specific fields:
PrivateArk Safe: The name of the safe in CyberArk containing the certificate store password you wish to use.
Application ID: The name of the application created in CyberArk for use with Keyfactor Command.
Because these fields are configured on the PAM provider definition, they appear as InstanceLevel=False like so:

<pre>{
   "Id": 1,
   "Name": "Safe",
   "DisplayName": "Priv-
ateArk Safe",
   "DataType": 1,
   "InstanceLevel": false,</pre></td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Name	Description
	Value / **Description**

Value	Description
	Value / **Description**

Value	Description
	

```
   "ProviderType": null
},
{
   "Id": 4,
   "Name": "AppId",
   "DisplayName": "Applic-
ation ID",
   "DataType": 1,
   "InstanceLevel": false,
   "ProviderType": null
}
```

When you configure a certificate store to use CyberArk as a credential provider, you enter the name of the folder in the CyberArk safe where the protected object is stored and you enter the name of the projected object in the CyberArk safe containing the username or password used to access the certificate store. Because these fields are configured on the certificate store level, they appear as InstanceLevel=True like so:

```
{
   "Id": 2,
   "Name": "Folder",
   "DisplayName": "Priv-
ateArk Folder Name",
   "DataType": 1,
   "InstanceLevel": true,
   "ProviderType": null
},
{
   "Id": 3,
   "Name": "Object",
```

Name	Description
	Value / **Description** **Value** / **Description**  `"DisplayName": "PrivateArk Protected Password Name", "DataType": 1, "InstanceLevel": true, "ProviderType": null }` In both cases, the *values* for the fields (e.g. the actual name of the object in CyberArk where the password is stored) are stored in the *ProviderTypeParamValues* array. ProviderType — An array containing details for the provider type. Provider type parameters include: **Value** / **Description** Id — The Keyfactor Command reference GUID for the PAM provider type parameter. Name — A string indicating the internal name for the PAM provider type parameter.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.20.7 PUT PAM Providers

The PUT /PamProviders method updates an existing PAM provider. This method returns HTTP 200 OK on a success with details for the updated provider.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
CertificateStoreManagement: *Modify*
PrivilegedAccessManagement: *Modify*
SystemSettings: *Read*

Warning: Any previously populated fields that are not submitted with their full existing data using this method will be cleared of their existing data. When using this method, you should first do a GET to retrieve all the values for the record you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing.

Table 404: PUT PamProviders Response Data

Name	Description
ID	An integer indicating the Keyfactor Command reference ID for the PAM provider. This ID is automatically set by Keyfactor Command.
Name	A string indicating the name of the PAM provider. This name used to identify the PAM provider throughout Keyfactor.
Area	An integer indicating the area of Keyfactor Command the provider is used for. PAM providers generally have a value of 1, indicating they are used for certificate stores.
ProviderType	An array containing details about the provider type for the provider. Provider type details include:

Value	Description
Id	A string indicating the Keyfactor Command reference GUID for the provider type.
Name	A string indicating the name of the provider type.
ProviderTypeParams	An array of parameters that the provider type uses for data input in Keyfactor Command when creating new PAM provider and certificate store records. Provider type parameters values include:

Value	Description
Id	An integer indicating the Keyfactor Command reference ID for the PAM provider type parameter.
Name	A string indicating the internal name for the PAM provider type parameter.
DisplayName	A string indicating the display name for the PAM provider type parameter. For parameters with an *InstanceLevel* of *False*, this name appears on the PAM provider dialog for the parameter when a user creates a new PAM provider. For parameters with an *InstanceLevel* of *True*, this name appears on the Server dialog for the parameter when a user creates a new PAM provider.

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>DataType</td><td>An integer indicating the data type for the parameter. Possible values are:
1 = String
2 = Secret</td></tr>
<tr><td>InstanceLevel</td><td>A Boolean that sets whether the parameter is used to define the underlying PAM provider (False) or a field that needs to be set to a value when configuring a certificate store to use the PAM provider (True).

  Example: For CyberArk when defining a PAM provider, you configure two CyberArk-specific fields:
PrivateArk Safe: The name of the safe in CyberArk containing the certificate store password you wish to use.
Application ID: The name of the application created in CyberArk for use with Keyfactor Command.
Because these fields are configured on the PAM provider definition, they appear as InstanceLevel=False like so:

<pre>{
   "Id": 1,
   "Name": "Safe",
   "DisplayName": "Priv-
ateArk Safe",
   "DataType": 1,
   "InstanceLevel": false,</pre></td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Name	Description
	Value / **Description**
	Value / **Description**

```
   "ProviderType": null
},
{
   "Id": 4,
   "Name": "AppId",
   "DisplayName": "Applic-
ation ID",
   "DataType": 1,
   "InstanceLevel": false,
   "ProviderType": null
}
```

When you configure a certificate store to use CyberArk as a credential provider, you enter the name of the folder in the CyberArk safe where the protected object is stored and you enter the name of the projected object in the CyberArk safe containing the username or password used to access the certificate store. Because these fields are configured on the certificate store level, they appear as InstanceLevel=True like so:

```
{
   "Id": 2,
   "Name": "Folder",
   "DisplayName": "Priv-
ateArk Folder Name",
   "DataType": 1,
   "InstanceLevel": true,
   "ProviderType": null
},
{
   "Id": 3,
   "Name": "Object",
```

<pre>
   "DisplayName": "Priv-
ateArk Protected Password
Name",
   "DataType": 1,
   "InstanceLevel": true,
   "ProviderType": null
}
</pre>
In both cases, the values for the fields (e.g. the actual name of the object in CyberArk where the password is stored) are stored in the ProviderTypeParamValues array.</td></tr>
<tr><td>ProviderType</td><td>An array containing details for the provider type. Provider type parameters include:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>Id</td><td>The Keyfactor Command reference GUID for the PAM provider type parameter.</td></tr>
<tr><td>Name</td><td>A string indicating the internal name for the PAM provider type parameter.</td></tr>
</table>
</td></tr>

</table>
</td></tr>
</table>
</td></tr>
</table>
</td></tr>
<tr><td>SecureAreaId</td><td>An integer indicating the Keyfactor Command reference ID for the certificate store container the PAM provider is associated with, if any.
You can create a single PAM provider for each provider type (e.g. CyberArk), however, if you have opted to organize your certificate stores into containers, you will need to create multiple providers to match your container organization structure. The container field in the PAM provider definition is not required, but if one is supplied when creating a PAM provider, the PAM provider can only be used with certificate stores in the matching container. Likewise, a PAM provider defined with no container would be available for selection when setting pass-</td></tr>
</table>

Name	Description
	words for any certificate store that also did not specify a container. A PAM provider configured in this way could be used across a variety of certificate stores (e.g. both JKS and F5) as long as they were not in containers.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.21 Reports

The Reports component of the Keyfactor API includes methods necessary to list, update, and schedule built-in reports as well as methods to create, update, list and delete custom reports.

Table 405: Reports Endpoints

Endpoint	Method	Description	Link
/{id}	GET	Returns the built-in report with the specified ID.	GET Reports ID on the next page
/Custom/{id}	DELETE	Deletes the custom report with the specified ID.	DELETE Reports Custom ID on page 1504
/Custom/{id}	GET	Returns the custom report with the specified ID.	GET Reports Custom ID on page 1505
/Schedules/{id}	DELETE	Deletes the schedule for the built-in report with the specified schedule ID.	DELETE Reports Schedules ID on page 1506
/Schedules/{id}	GET	Returns the schedule for the built-in report with the specified schedule ID.	GET Reports Schedules ID on page 1506
/{id}/Parameters	GET	Returns the parameters for the built-in report with the specified report ID.	GET Reports ID Parameters on page 1510
/{id}/Parameters	PUT	Updates the parameters for the built-in report with the specified report ID.	PUT Reports ID Parameters on page 1511
/	GET	Returns all built-in reports with filtering and output options.	GET Reports on page 1513
/	PUT	Updates the built-in report with the specified ID. Only some fields can be updated.	PUT Reports on page 1516
/Custom	GET	Returns all custom reports with filtering and	GET Reports Custom on

Endpoint	Method	Description	Link
		output options.	page 1519
/Custom	POST	Creates a custom report.	POST Reports Custom on page 1521
/Custom	PUT	Updates the custom report with the specified ID.	PUT Reports Custom on page 1523
/{id}/Schedules	GET	Returns the schedule for the built-in report with the specified report ID.	GET Reports ID Schedules on page 1524
/{id}/Schedules	POST	Creates a schedule for the built-in report with the specified report ID.	POST Reports ID Schedules on page 1528
/{id}/Schedules	PUT	Updates a schedule for the built-in report with the specified report ID.	PUT Reports ID Schedules on page 1537

3.2.21.1 GET Reports ID

The GET /Reports/{id} method is used to return the built-in report with the specified ID. This method returns HTTP 200 OK on a success with the details of the report.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: Reports: *Read*

Table 406: GET Reports {id} Input Parameters

Name	In	Description
id	Path	**Required**. An integer containing the Keyfactor Command reference ID for the report that should be retrieved. Use the *GET /Reports* method (see GET Reports on page 1513) to retrieve a list of your built-in reports to determine the report ID to use.

Table 407: GET Reports {id} Response Data

Name	Description
Id	An integer containing the Keyfactor Command reference ID for the report.
DisplayName	A string containing the display name for the report. This appears in the Keyfactor Command Management Portal on the Report Manager page, at the top of the page for the generated report, and on the menu. **Tip:** Exported reports use built-in names; modifying this value will not change the name that appears at the top of the exported version of a report (e.g. a PDF).
Description	A string containing the description for the report. This appears in the Keyfactor Command Management Portal on the Report Manager page and at the top of the page for the generated report.
ReportPath	A string containing the name of the report as referenced when retrieving it via Logi Analytics.
VersionNumber	A string containing the version number for the report.
Categories	A string containing the report category or categories in which the report is found on the report manager page in the Keyfactor Command Management Portal. The possible values are: • CertificateCounts • CertificateLifecycle • CertificateLocations • PKIOperations • SecurityVulnerability • SSHKeys
ShortName	A string containing the short reference name for the report.
InNavigator	A Boolean that indicates whether the report has been configured to display on the Keyfactor Command Management Portal menu (true) or not (false).
Favorite	A Boolean that indicates whether the report has been marked as a favorite (true) or not (false).
RemoveDuplicates	A Boolean that indicates whether the report uses certificate de-duping logic in producing output (true) or not (false). **Tip:** When de-duplication is enabled for a report, the report results will include only the most recently issued certificate if there is more than one certificate that matches the de-duplication criteria. De-duplication can only be enabled for reports that use certificate collections—the *UsesCollection* parameter. The *UsesCollection* parameter is not user-configurable. Certificate de-duping is configured on a certificate collection using the *DuplicationField* parameter (see POST Certificate Collections on page 1081). This corresponds to the Keyfactor

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>Command Management Portal "Ignore renewed certificate results by" option on a certificate collection. Certificate collections may be configured to be de-duplicated based on the certificate common name, distinguished name, or principal name (or not at all). Only certificates that share all the EKUs (e.g. Client Authentication and Server Authentication) as well as the same CN, DN or UPN will be eliminated as duplicates. If a certificate has more than one EKU and at least one EKU does not match an otherwise similar certificate with matching CN, DN or UPN, it will not be eliminated.</td></tr>
<tr><td>UsesCollection</td><td>A Boolean that indicates whether the report uses a certificate collection as input for reporting (true) or not (false).</td></tr>
<tr><td>ReportParameter</td><td>An array containing the parameters for the report. . Report parameters include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>The Keyfactor Command reference ID of the report parameter.</td></tr>
<tr><td>ParameterName</td><td>A string containing the short reference name for the report parameter (e.g. EvalDate).</td></tr>
<tr><td>ParameterType</td><td>A string containing the type of the parameter. Possible values include:
Bool
CertAuth (certificate authorities)
Int
Metadata
OrchestratorPool
RelativeDate
SingleCA
SingleMetadata
SSHKeyType
Templates
TimePeriod</td></tr>
<tr><td>DisplayName</td><td>A string containing the display name for the parameter (e.g. Evaluation Date (UTC)).</td></tr>
<tr><td>Description</td><td>A string containing the description for the parameter.</td></tr>
<tr><td>DefaultValue</td><td>A string containing the default value for the parameter.</td></tr>
</table></td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>Tip: Default values that are integers are also stored as strings in this parameter.</td></tr>
<tr><td>DisplayOrder</td><td>An integer indicating the order in which the parameters should be displayed on the scheduling page in Keyfactor Command, beginning with 0.</td></tr>
<tr><td>ParameterVisibility</td><td>A string indicating whether the parameter should be displayed in the Keyfactor Command Management Portal. The default value is Visible. The alternative setting is Hidden.</td></tr>
</table>
</td></tr>
<tr><td>Schedules</td><td>An array containing the configured schedules for running the report, if any. Schedules include the following information:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>The Keyfactor Command reference ID of the report schedule.</td></tr>
<tr><td>SendReport</td><td>A Boolean indicating whether the report will be sent to the email recipients configured in EmailRecipients (true) or not (false).</td></tr>
<tr><td>SaveReport</td><td>A Boolean indicating whether the report will be saved to the UNC path defined by SaveReportPath (true) or not (false).</td></tr>
<tr><td>SaveReportPath</td><td>A string containing the UNC path to which the report will be written, if configured.</td></tr>
<tr><td>ReportFormat</td><td>A string containing the report format selected for the scheduled report run. Supported values vary depending on the selected report and include:
PDF
Excel
CSV</td></tr>
<tr><td>KeyfactorSchedule</td><td>An array providing the schedule for the report. The schedule can be one of:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Name	Description
	Name / **Description**
	Name: Daily **Description**: A dictionary that indicates a job scheduled to run every day at the same time with the parameter: **Name** / **Description** Time — The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z). For example, daily at 11:30 pm: `"Daily": { "Time": "2022-02-25T23:30:00Z" }`
	Name: Weekly **Description**: A dictionary that indicates a job scheduled to run on a specific day or days every week at the same time with the parameters: **Name** / **Description** Time — The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z). Days — An array of values representing the days of the week on which to run the job. These can either be entered as integers (0 for Sunday, 1 for Monday, etc.) or as days of the week (e.g. "Sunday"). For example, every Monday, Wednesday and Friday at 5:30 pm:

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>

```
"Weekly": {
   "Days": [
      "Monday",
      "Wednesday",
      "Friday"
   ],
   "Time": "2022-02-27T17:30:00Z"
}
```

</td></tr>
<tr><td>Monthly</td><td>A dictionary that indicates a job scheduled to run on a specific day or days every month at the same time with the parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
<tr><td>Day</td><td>The number of the day, in the month, to run the job.</td></tr>
</table>
For example, on the first of every month at 5:30 pm:

```
"Monthly": {
   "Day": 1
   "Time": "2022-02-27T17:30:00Z"
}
```

</td></tr>
</table>

Note: Although the Swagger Example Value may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint.
</td></tr>
<tr><td>EmailRecipients</td><td>An array containing the email addresses of users configured as recipients of the scheduled report, if any.</td></tr>
</table>
</td></tr>
</table>

Name	Description
	Name / **Description** RuntimePara-meters: Any array containing the parameters to be used at run time configured in the report schedule. Runtime parameters will vary depending on the report selected. Runtime parameters may include things such as:

Name	Description
CertAuth	The certificate authority or authorities selected to report on.
EndDate	The end date selected for the reporting period to report on. This is configured as a certain number of days, weeks or months before or after the current date (e.g. 0 days before today—meaning today).
EvalDate	The evaluation date selected for the reporting period to report on. This is configured as a certain number of days, weeks or months before or after the current date (e.g. 30 days before today).
Metadata	The custom metadata fields selected to include in the report.
MinCertCount	The minimum number of certificates that must have been issued for the given template before the template will be included in the report.
OrchestratorPool	The orchestrator pool selected to report on.
PeriodCount	The number of days, weeks or months selected to report on.
PeriodSize	The selected reporting period (day, weeks or months).
Requesters	The certificate requesters selected to include in the report.
SSHKeyType	The SSH key type(s) selected to report on.

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>StartDate</td><td>The start date selected for the reporting period to report on. This is configured as a certain number of days, weeks or months before or after the current date (e.g. 30 days before today).</td></tr>
<tr><td>TemplateIds</td><td>The Keyfactor Command identifiers for the templates to include in the report.</td></tr>
</table>
</td></tr>
</table>
</td></tr>
<tr><td>Accep-tedSched-uleFormats</td><td>An array containing the report formats supported for the report. Typically supported formats are PDF and Excel. Select reports support CSV format.</td></tr>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.21.2 DELETE Reports Custom ID

The DELETE /Reports/Custom/{id} method is used to delete the custom report link with the specified ID. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: Reports: *Modify*

Table 408: DELETE Reports Custom {id} Input Parameters

Name	In	Description
id	Path	**Required**. An integer containing the Keyfactor Command reference ID for the report link to be deleted. Use the *GET /Reports/Custom* method (see GET Reports Custom on page 1519) to retrieve a list of your custom report links to determine the report ID to use.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.21.3 GET Reports Custom ID

The GET /Reports/Custom/{id} method is used to return the custom report link with the specified ID. This method returns HTTP 200 OK on a success with the details of the report linkage.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: Reports: *Read*

Table 409: GET Reports Custom {id} Input Parameters

Name	In	Description
id	Path	**Required**. An integer containing the Keyfactor Command reference ID for the report link that should be retrieved.

Table 410: GET Reports Custom {id} Response Data

Name	Description
CustomURL	A string containing the URL users should click from within Keyfactor Command to display the custom report (e.g. https://mywebserver.keyexample.com/mycustomreport/). **Tip:** Custom reports are automatically opened in a new browser tab.
Id	An integer containing the Keyfactor Command reference ID for the report link.
DisplayName	A string containing the display name for the report. This appears in the Keyfactor Command Management Portal on the Report Manager page and on the menu.
Description	A string containing the description for the report. This appears in the Keyfactor Command Management Portal on the Report Manager page.
InNavigator	A Boolean that indicates whether the report has been configured to display on the Keyfactor Command Management Portal menu (true) or not (false).
Favorite	A Boolean that indicates whether the report has been marked as a favorite (true) or not (false).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.21.4 DELETE Reports Schedules ID

The DELETE /Reports/Schedules/{id} method is used to delete the schedule for the built-in report with the specified schedule ID. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
Reports: *Modify*

Table 411: DELETE Reports Schedules {id} Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID of the report schedule. Use the *GET /Reports* method (see GET Reports on page 1513) to retrieve a list of your built-in reports to determine the report ID and then *GET /Reports/{id}* (see GET Reports ID on page 1497) to retrieve the details for that report to determine the schedule ID to use.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.21.5 GET Reports Schedules ID

The GET /Reports/Schedules/{id} method is used to return the schedule for the built-in report with the specified **schedule** ID. This method returns HTTP 200 OK on a success with the details of the report schedule. Use the *GET /Reports/{id}/Schedules* method to return the schedule based on the **report** ID (see GET Reports ID Schedules on page 1524).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
Reports: *Read*

Table 412: GET Reports Schedules {id} Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID of the report schedule. Use the *GET /Reports* method (see GET Reports on page 1513) to retrieve a list of your built-in reports to determine the report ID and then *GET /Reports/{id}* (see GET Reports ID on page 1497) to retrieve the details for that report to determine the schedule ID to use.

Table 413: GET Reports Schedules {id} Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>The Keyfactor Command reference ID of the report schedule.</td></tr>
<tr><td>SendReport</td><td>A Boolean indicating whether the report will be sent to the email recipients configured in EmailRecipients (true) or not (false).</td></tr>
<tr><td>SaveReport</td><td>A Boolean indicating whether the report will be saved to the UNC path defined by SaveReportPath (true) or not (false).</td></tr>
<tr><td>SaveReportPath</td><td>A string containing the UNC path to which the report will be written, if configured.</td></tr>
<tr><td>ReportFormat</td><td>A string containing the report format selected for the scheduled report run. Supported values vary depending on the selected report and include:
PDF
Excel
CSV</td></tr>
<tr><td>KeyfactorSchedule</td><td>An array providing the schedule for the report. The schedule can be one of:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
<tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, daily at 11:30 pm:
<pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre></td></tr>
<tr><td>Weekly</td><td>A dictionary that indicates a job scheduled to run on a specific day or days every week at the same time with the parameters:</td></tr>
</table></td></tr>
</table>

Name	Description
	Name / **Description**
	Name / **Description**
	Time — The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).
	Days — An array of values representing the days of the week on which to run the job. These can either be entered as integers (0 for Sunday, 1 for Monday, etc.) or as days of the week (e.g. "Sunday").

For example, every Monday, Wednesday and Friday at 5:30 pm:

```
"Weekly": {
   "Days": [
      "Monday",
      "Wednesday",
      "Friday"
   ],
   "Time": "2022-02-27T17:30:00Z"
}
```

Monthly — A dictionary that indicates a job scheduled to run on a specific day or days every month at the same time with the parameters:

Name	Description
Time	The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).
Day	The number of the day, in the month, to run the job.

For example, on the first of every month at 5:30 pm:

```
"Monthly": {
   "Day": 1
   "Time": "2022-02-27T17:30:00Z"
}
```

Note: Although the Swagger *Example Value* may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this

Name	Description
	functionality—are valid for this endpoint.
EmailRecipients	An array containing the email addresses of users configured as recipients of the scheduled report, if any.
RuntimePara-meters	Any array containing the parameters to be used at run time configured in the report schedule. Runtime parameters will vary depending on the report selected. Runtime parameters may include things such as:

Name	Description
CertAuth	The certificate authority or authorities selected to report on.
EndDate	The end date selected for the reporting period to report on. This is configured as a certain number of days, weeks or months before or after the current date (e.g. 0 days before today—meaning today).
EvalDate	The evaluation date selected for the reporting period to report on. This is configured as a certain number of days, weeks or months before or after the current date (e.g. 30 days before today).
Metadata	The custom metadata fields selected to include in the report.
MinCertCount	The minimum number of certificates that must have been issued for the given template before the template will be included in the report.
OrchestratorPool	The orchestrator pool selected to report on.
PeriodCount	The number of days, weeks or months selected to report on.
PeriodSize	The selected reporting period (day, weeks or months).
Requesters	The certificate requesters selected to include in the report.
SSHKeyType	The SSH key type(s) selected to report on.
StartDate	The start date selected for the reporting period to report on. This is configured as a certain number of days, weeks or months before or after the current date (e.g. 30 days before today).
TemplateIds	The Keyfactor Command identifiers for the templates to include in the report.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.21.6 GET Reports ID Parameters

The GET /Reports/{id}/Parameters method is used to return the parameters for the built-in report with the specified report ID. This method returns HTTP 200 OK on a success with the details of the report parameters.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: Reports: *Read*

Table 414: GET Reports {id} Parameters Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID of the built-in **report** the parameter is associated with. Use the *GET /Reports* method (see GET Reports on page 1513) to retrieve a list of your built-in reports to determine the report ID to use.

Table 415: GET Reports {id} Parameters Response Data

Name	Description
Id	The Keyfactor Command reference ID of the report **parameter**.
ParameterName	A string containing the short reference name for the report parameter (e.g. EvalDate).
ParameterType	A string containing the type of the parameter. Possible values include: • Bool • CertAuth (certificate authorities) • Int • Metadata • OrchestratorPool • RelativeDate • SingleCA • SingleMetadata • SSHKeyType • Templates • TimePeriod
DisplayName	A string containing the display name for the parameter (e.g. Evaluation Date (UTC)).
Description	A string containing the description for the parameter.
DefaultValue	A string containing the default value for the parameter. **Tip:** Default values that are integers are also stored as strings in this parameter.
DisplayOrder	An integer indicating the order in which the parameters should be displayed on the scheduling page in Keyfactor Command, beginning with 0.
ParameterVisibility	A string indicating whether the parameter should be displayed in the Keyfactor Command Management Portal. The default value is *Visible*. The alternative setting is *Hidden*.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.21.7 PUT Reports ID Parameters

The PUT /Reports/{id}/Parameters method is used to update the parameters for the built-in report with the specified report ID. Only some fields can be updated. This method returns HTTP 200 OK on a success with the details of the report parameters.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: Reports: *Modify*

Table 416: PUT Reports {id} Parameters Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID of the built-in **report** the parameter is associated with. Use the *GET /Reports* method (see GET Reports on the next page) to retrieve a list of your built-in reports to determine the report ID to use.
Id	Body	**Required**. The Keyfactor Command reference ID of the report **parameter**. Use the *GET /Reports/{id}* (see GET Reports ID on page 1497) to retrieve the details for the desired report to determine the parameter ID to use.
DisplayName	Body	A string containing the display name for the parameter (e.g. Evaluation Date (UTC)).
Description	Body	A string containing the description for the parameter.
DefaultValue	Body	A string containing the default value for the parameter. **Tip:** Default values that are integers are also stored as strings in this parameter.

Table 417: PUT Reports {id} Parameters Response Data

Name	Description
Id	The Keyfactor Command reference ID of the report **parameter**.
ParameterName	A string containing the short reference name for the report parameter (e.g. EvalDate).
ParameterType	A string containing the type of the parameter. Possible values include: • Bool • CertAuth (certificate authorities) • Int • Metadata • OrchestratorPool • RelativeDate • SingleCA • SingleMetadata • SSHKeyType • Templates • TimePeriod
DisplayName	A string containing the display name for the parameter (e.g. Evaluation Date (UTC)).
Description	A string containing the description for the parameter.
DefaultValue	A string containing the default value for the parameter. **Tip:** Default values that are integers are also stored as strings in this parameter.
DisplayOrder	An integer indicating the order in which the parameters should be displayed on the scheduling page in Keyfactor Command, beginning with 0.
ParameterVisibility	A string indicating whether the parameter should be displayed in the Keyfactor Command Management Portal. The default value is *Visible*. The alternative setting is *Hidden*.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.21.8 GET Reports

The GET /Reports method is used to return all built-in reports with filtering and output options. This method returns HTTP 200 OK on a success with selected details of the reports. To view details of schedules and parameters for a report, use the *GET /Reports/{id}* method (see GET Reports ID on page 1497).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: Reports: *Read*

Table 418: GET Reports Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Certificate Search Page on page 31. The query fields supported for this endpoint are: • *Categories* (CertificateCounts, CertificateLifecycle, Certificate Locations, PKIOperations, SecurityVulnerability,SSHKeys) • *Custom* • *Favorite* (true, false) • *InNavigator* (true, false) • *Scheduled* (Number of schedules) **Tip:** This method offers limited searchable fields. The most useful search is probably by category. For example, to return all the reports tagged with the PKI Operations category: `Categories -contains "PKIOperations"`
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *DisplayName*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 419: GET Reports Response Data

Name	Description
Id	An integer containing the Keyfactor Command reference ID for the report.
Scheduled	An integer indicating the number of schedules configured for the report.
DisplayName	A string containing the display name for the report. This appears in the Keyfactor Command Management Portal on the Report Manager page, at the top of the page for the generated report, and on the menu. **Tip:** Exported reports use built-in names; modifying this value will not change the name that appears at the top of the exported version of a report (e.g. a PDF).
Description	A string containing the description for the report. This appears in the Keyfactor Command Management Portal on the Report Manager page and at the top of the page for the generated report.
ReportPath	A string containing the name of the report as referenced when retrieving it via Logi Analytics.
VersionNumber	A string containing the version number for the report.
Categories	A string containing the report category or categories in which the report is found on the report manager page in the Keyfactor Command Management Portal. The possible values are: • CertificateCounts • CertificateLifecycle • CertificateLocations • PKIOperations • SecurityVulnerability • SSHKeys
ShortName	A string containing the short reference name for the report.
InNavigator	A Boolean that indicates whether the report has been configured to display on the Keyfactor Command Management Portal menu (true) or not (false).
Favorite	A Boolean that indicates whether the report has been marked as a favorite (true) or not (false).
RemoveDuplicates	A Boolean that indicates whether the report uses certificate de-duping logic in producing output (true) or not (false). **Tip:** When de-duplication is enabled for a report, the report results will include only the most recently issued certificate if there is more than one certificate that matches the de-duplication criteria. De-duplication can only be enabled for reports that use certificate collections—the *UsesCollection* parameter. The *UsesCollection* parameter is not user-configurable.

Name	Description
	Certificate de-duping is configured on a certificate collection using the *DuplicationField* parameter (see POST Certificate Collections on page 1081). This corresponds to the Keyfactor Command Management Portal "Ignore renewed certificate results by" option on a certificate collection. Certificate collections may be configured to be de-duplicated based on the certificate common name, distinguished name, or principal name (or not at all). Only certificates that share all the EKUs (e.g. Client Authentication and Server Authentication) as well as the same CN, DN or UPN will be eliminated as duplicates. If a certificate has more than one EKU and at least one EKU does not match an otherwise similar certificate with matching CN, DN or UPN, it will not be eliminated.
UsesCollection	A Boolean that indicates whether the report uses a certificate collection as input for reporting (true) or not (false).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.21.9 PUT Reports

The PUT /Reports method is used to update the built-in report with the specified report ID. Only some fields can be updated. To create or update a report schedule, use the *POST /Reports/{id}Schedules* (see POST Reports ID Schedules on page 1528) or *PUT /Reports/{id}Schedules* (see PUT Reports ID Schedules on page 1537) method. To update parameters for a built-in report, use the *PUT /Reports/{id}/Parameters* method (see PUT Reports ID Parameters on page 1511). This method returns HTTP 200 OK on a success with the details of the report.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
Reports: *Modify*

Table 420: PUT Reports Input Parameters

Name	In	Description
Id	Body	**Required**. The Keyfactor Command reference ID of the built-in report that should be updated. Use the *GET /Reports* method (see GET Reports on page 1513) to retrieve a list of your built-in reports to determine the report ID to use.
InNavigator	Body	A Boolean that indicates whether the report has been configured to display on the Keyfactor Command Management Portal menu (true) or not (false).
Favorite	Body	A Boolean that indicates whether the report has been marked as a favorite (true) or not (false).
RemoveDuplicates	Body	A Boolean that indicates whether the report uses certificate de-duping logic in producing output (true) or not (false). **Tip:** When de-duplication is enabled for a report, the report results will include only the most recently issued certificate if there is more than one certificate that matches the de-duplication criteria. De-duplication can only be enabled for reports that use certificate collections—the *UsesCollection* parameter. The *UsesCollection* parameter is not user-configurable. Certificate de-duping is configured on a certificate collection using the *DuplicationField* parameter (see POST Certificate Collections on page 1081). This corresponds to the Keyfactor Command Management Portal "Ignore renewed certificate results by" option on a certificate collection. Certificate collections may be configured to be de-duplicated based on the certificate common name, distinguished name, or principal name (or not at all). Only certificates that share all the EKUs (e.g. Client Authentication and Server Authentication) as well as the same CN, DN or UPN will be eliminated as duplicates. If a certificate has more than one EKU and at least one EKU does not match an otherwise similar certificate with matching CN, DN or UPN, it will not be eliminated.

Table 421: PUT Reports Response Data

Name	Description
Id	An integer containing the Keyfactor Command reference ID for the report.
DisplayName	A string containing the display name for the report. This appears in the Keyfactor Command Management Portal on the Report Manager page, at the top of the page for the generated report, and on the menu. **Tip:** Exported reports use built-in names; modifying this value will not change the name that appears at the top of the exported version of a report (e.g. a PDF).
Description	A string containing the description for the report. This appears in the Keyfactor Command Management Portal on the Report Manager page and at the top of the page for the generated report.
ReportPath	A string containing the name of the report as referenced when retrieving it via Logi Analytics.
VersionNumber	A string containing the version number for the report.
Categories	A string containing the report category or categories in which the report is found on the report manager page in the Keyfactor Command Management Portal. The possible values are: • CertificateCounts • CertificateLifecycle • CertificateLocations • PKIOperations • SecurityVulnerability • SSHKeys
ShortName	A string containing the short reference name for the report.
InNavigator	A Boolean that indicates whether the report has been configured to display on the Keyfactor Command Management Portal menu (true) or not (false).
Favorite	A Boolean that indicates whether the report has been marked as a favorite (true) or not (false).
RemoveDuplicates	A Boolean that indicates whether the report uses certificate de-duping logic in producing output (true) or not (false). **Tip:** When de-duplication is enabled for a report, the report results will include only the most recently issued certificate if there is more than one certificate that matches the de-duplication criteria. De-duplication can only be enabled for reports that use certificate collections—the *UsesCollection* parameter. The *UsesCollection* parameter is not user-configurable. Certificate de-duping is configured on a certificate collection using the *DuplicationField*

Name	Description
	parameter (see POST Certificate Collections on page 1081). This corresponds to the Keyfactor Command Management Portal "Ignore renewed certificate results by" option on a certificate collection. Certificate collections may be configured to be de-duplicated based on the certificate common name, distinguished name, or principal name (or not at all). Only certificates that share all the EKUs (e.g. Client Authentication and Server Authentication) as well as the same CN, DN or UPN will be eliminated as duplicates. If a certificate has more than one EKU and at least one EKU does not match an otherwise similar certificate with matching CN, DN or UPN, it will not be eliminated.
UsesCollection	A Boolean that indicates whether the report uses a certificate collection as input for reporting (true) or not (false).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.21.10 GET Reports Custom

The GET /Reports/Custom method is used to return all custom report links with filtering and output options. This method returns HTTP 200 OK on a success with the details of the report linkages.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
Reports: *Read*

Table 422: GET Reports Custom Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Certificate Search Page on page 31. The query fields supported for this endpoint are: • *Categories* (CertificateCounts, CertificateLifecycle, Certificate Locations, PKIOperations, SecurityVulnerability,SSHKeys) • *Custom* • *Favorite* (true, false) • *InNavigator* (true, false) • *Scheduled* (Number of schedules)
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *DisplayName*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 423: GET Reports Custom Response Data

Name	Description
CustomURL	A string containing the URL users should click from within Keyfactor Command to display the custom report (e.g. https://mywebserver.keyexample.com/mycustomreport/). **Tip:** Custom reports are automatically opened in a new browser tab.
Id	An integer containing the Keyfactor Command reference ID for the report link.
DisplayName	A string containing the display name for the report. This appears in the Keyfactor Command Management Portal on the Report Manager page and on the menu.
Description	A string containing the description for the report. This appears in the Keyfactor Command Management Portal on the Report Manager page.
InNavigator	A Boolean that indicates whether the report has been configured to display on the Keyfactor Command Management Portal menu (true) or not (false).
Favorite	A Boolean that indicates whether the report has been marked as a favorite (true) or not (false).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.21.11 POST Reports Custom

The POST /Reports/Custom method is used to add a link within Keyfactor Command to an externally hosted custom report. This method returns HTTP 200 OK on a success with the details of the report linkage.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
Reports: *Modify*

Table 424: POST Reports Custom Input Parameters

Name	In	Description
CustomURL	Body	**Required**. A string containing the URL users should click from within Keyfactor Command to display the custom report (e.g. https://my-webserver.keyexample.com/mycustomreport/). **Tip:** Custom reports are automatically opened in a new browser tab.
DisplayName	Body	**Required**. A string containing the display name for the report. This appears in the Keyfactor Command Management Portal on the Report Manager page and on the menu.
Description	Body	A string containing the description for the report. This appears in the Keyfactor Command Management Portal on the Report Manager page.
InNavigator	Body	A Boolean that indicates whether the report has been configured to display on the Keyfactor Command Management Portal menu (true) or not (false). The default is *false*.
Favorite	Body	A Boolean that indicates whether the report has been marked as a favorite (true) or not (false). The default is *false*.

Table 425: POST Reports Custom Response Data

Name	Description
CustomURL	A string containing the URL users should click from within Keyfactor Command to display the custom report (e.g. https://mywebserver.keyexample.com/mycustomreport/). **Tip:** Custom reports are automatically opened in a new browser tab.
Id	An integer containing the Keyfactor Command reference ID for the report link.
DisplayName	A string containing the display name for the report. This appears in the Keyfactor Command Management Portal on the Report Manager page and on the menu.
Description	A string containing the description for the report. This appears in the Keyfactor Command Management Portal on the Report Manager page.
InNavigator	A Boolean that indicates whether the report has been configured to display on the Keyfactor Command Management Portal menu (true) or not (false).
Favorite	A Boolean that indicates whether the report has been marked as a favorite (true) or not (false).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.21.12 PUT Reports Custom

The PUT /Reports/Custom method is used to update the custom report link with the specified ID. This method returns HTTP 200 OK on a success with the details of the report linkage.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: Reports: *Modify*

Table 426: PUT Reports Custom Input Parameters

Name	In	Description
CustomURL	Body	**Required**. A string containing the URL users should click from within Keyfactor Command to display the custom report (e.g. https://my-webserver.keyexample.com/mycustomreport/). **Tip:** Custom reports are automatically opened in a new browser tab.
Id	Body	**Required**. An integer containing the Keyfactor Command reference ID for the report link. Use the *GET /Reports/Custom* method (see GET Reports Custom on page 1519) to retrieve a list of your custom report links to determine the report ID to use.
DisplayName	Body	**Required**. A string containing the display name for the report. This appears in the Keyfactor Command Management Portal on the Report Manager page and on the menu.
Description	Body	A string containing the description for the report. This appears in the Keyfactor Command Management Portal on the Report Manager page.
InNavigator	Body	A Boolean that indicates whether the report has been configured to display on the Keyfactor Command Management Portal menu (true) or not (false). The default is *false*.
Favorite	Body	A Boolean that indicates whether the report has been marked as a favorite (true) or not (false). The default is *false*.

Table 427: PUT Reports Custom Response Data

Name	Description
CustomURL	A string containing the URL users should click from within Keyfactor Command to display the custom report (e.g. https://mywebserver.keyexample.com/mycustomreport/). **Tip:** Custom reports are automatically opened in a new browser tab.
Id	An integer containing the Keyfactor Command reference ID for the report link.
DisplayName	A string containing the display name for the report. This appears in the Keyfactor Command Management Portal on the Report Manager page and on the menu.
Description	A string containing the description for the report. This appears in the Keyfactor Command Management Portal on the Report Manager page.
InNavigator	A Boolean that indicates whether the report has been configured to display on the Keyfactor Command Management Portal menu (true) or not (false).
Favorite	A Boolean that indicates whether the report has been marked as a favorite (true) or not (false).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.21.13 GET Reports ID Schedules

The GET /Reports/{id}/Schedules method is used to return the schedule for the built-in report with the specified **report** ID. This method returns HTTP 200 OK on a success with the details of the report schedule. Use the *GET /Reports/Schedules/{id}* method to return the schedule based on the **schedule** ID (see GET Reports Schedules ID on page 1506).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
Reports: *Read*

Table 428: GET Reports {id} Schedules Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID of the built-in **report** the schedule is associated with. Use the *GET /Reports* method (see GET Reports on page 1513) to retrieve a list of your built-in reports to determine the report ID to use.

Table 429: GET Reports {id} Schedules Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>The Keyfactor Command reference ID of the report schedule.</td></tr>
<tr><td>SendReport</td><td>A Boolean indicating whether the report will be sent to the email recipients configured in EmailRecipients (true) or not (false).</td></tr>
<tr><td>SaveReport</td><td>A Boolean indicating whether the report will be saved to the UNC path defined by SaveReportPath (true) or not (false).</td></tr>
<tr><td>SaveReportPath</td><td>A string containing the UNC path to which the report will be written, if configured.</td></tr>
<tr><td>ReportFormat</td><td>A string containing the report format selected for the scheduled report run. Supported values vary depending on the selected report and include:
PDF
Excel
CSV</td></tr>
<tr><td>KeyfactorSchedule</td><td>An array providing the schedule for the report. The schedule can be one of:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
<tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, daily at 11:30 pm:
<pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre></td></tr>
<tr><td>Weekly</td><td>A dictionary that indicates a job scheduled to run on a specific day or days every week at the same time with the parameters:</td></tr>
</table></td></tr>
</table>

Name	Description
	Name / **Description**
	Name / **Description**
	Time — The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).
	Days — An array of values representing the days of the week on which to run the job. These can either be entered as integers (0 for Sunday, 1 for Monday, etc.) or as days of the week (e.g. "Sunday").

For example, every Monday, Wednesday and Friday at 5:30 pm:

```
"Weekly": {
   "Days": [
      "Monday",
      "Wednesday",
      "Friday"
   ],
   "Time": "2022-02-27T17:30:00Z"
}
```

Monthly — A dictionary that indicates a job scheduled to run on a specific day or days every month at the same time with the parameters:

Name	Description
Time	The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).
Day	The number of the day, in the month, to run the job.

For example, on the first of every month at 5:30 pm:

```
"Monthly": {
   "Day": 1
   "Time": "2022-02-27T17:30:00Z"
}
```

Note: Although the Swagger *Example Value* may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this

Name	Description
	functionality—are valid for this endpoint.
EmailRecipients	An array containing the email addresses of users configured as recipients of the scheduled report, if any.
RuntimePara-meters	Any array containing the parameters to be used at run time configured in the report schedule. Runtime parameters will vary depending on the report selected. Runtime parameters may include things such as:

Name	Description
CertAuth	The certificate authority or authorities selected to report on.
EndDate	The end date selected for the reporting period to report on. This is configured as a certain number of days, weeks or months before or after the current date (e.g. 0 days before today—meaning today).
EvalDate	The evaluation date selected for the reporting period to report on. This is configured as a certain number of days, weeks or months before or after the current date (e.g. 30 days before today).
Metadata	The custom metadata fields selected to include in the report.
MinCertCount	The minimum number of certificates that must have been issued for the given template before the template will be included in the report.
OrchestratorPool	The orchestrator pool selected to report on.
PeriodCount	The number of days, weeks or months selected to report on.
PeriodSize	The selected reporting period (day, weeks or months).
Requesters	The certificate requesters selected to include in the report.
SSHKeyType	The SSH key type(s) selected to report on.
StartDate	The start date selected for the reporting period to report on. This is configured as a certain number of days, weeks or months before or after the current date (e.g. 30 days before today).
TemplateIds	The Keyfactor Command identifiers for the templates to include in the report.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.21.14 POST Reports ID Schedules

The POST /Reports/{id}/Schedules method is used to create a schedule for the built-in report with the specified report ID. This method returns HTTP 200 OK on a success with the details of the report schedule.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
Reports: *Modify*

Table 430: POST Reports {id} Schedules Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>id</td><td>Path</td><td>Required. The Keyfactor Command reference ID of the built-in report the schedule is associated with.
Use the GET /Reports method (see <a>GET Reports on page 1513) to retrieve a list of your built-in reports to determine the report ID to use.</td></tr>
<tr><td>SendReport</td><td>Body</td><td>A Boolean indicating whether the report will be sent to the email recipients configured in EmailRecipients (true) or not (false). The default is false.</td></tr>
<tr><td>SaveReport</td><td>Body</td><td>A Boolean indicating whether the report will be saved to the UNC path defined by SaveReportPath (true) or not (false). The default is false.</td></tr>
<tr><td>SaveReportPath</td><td>Body</td><td>Required*. A string containing the UNC path to which the report will be written, if configured.
Note: The path for saved reports must be provided in UNC format (\\servername\sharename\path) and must be accessible from the Keyfactor Command administration server. In addition:
Do not use a trailing "\" in the report path.
Ensure that the application pool service account has permission to write to the location where you want the outputted report to be saved.
When scheduling a report, schedule it for at least 10 minutes in advance of the current time if you wish it to run soon. If you want to run it faster than that, the Keyfactor Command Service will need to be restarted.
This field is required if SaveReport is set to true.</td></tr>
<tr><td>ReportFormat</td><td>Body</td><td>Required. A string containing the report format selected for the scheduled report run. Supported values vary depending on the selected report and include:
PDF
Excel
CSV</td></tr>
<tr><td>KeyfactorSchedule</td><td>Body</td><td>Required. An array providing the schedule for the report. The schedule can be one of:<table><tr><th>Name</th><th>Description</th></tr><tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr><tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:</td></tr></table></td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, daily at 11:30 pm:
<pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre>
</td></tr>
<tr><td>Weekly</td><td>A dictionary that indicates a job scheduled to run on a specific day or days every week at the same time with the parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
<tr><td>Days</td><td>An array of values representing the days of the week on which to run the job. These can either be entered as integers (0 for Sunday, 1 for Monday, etc.) or as days of the week (e.g. "Sunday").</td></tr>
</table>
For example, every Monday, Wednesday and Friday at 5:30 pm:
<pre>"Weekly": {
   "Days": [
      "Monday",
      "Wednesday",
      "Friday"
   ],
   "Time": "2022-02-27T17:30:00Z"
}</pre>
</td></tr>
<tr><td>Monthly</td><td>A dictionary that indicates a job scheduled to run on a specific day or days every month at the same time with the parameters:</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>

   "pkiadmins@keyexample.com",
   "john.smith@keyexample.com"
]</pre>
This field is required if SendReport is set to true.</td></tr>
<tr><td>RuntimeParameters</td><td>Body</td><td>Required*. Any array containing the parameters to be used at run time configured in the report schedule. Runtime parameters will vary depending on the report selected. Runtime parameters may include things such as:

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>CertAuth</td><td>The certificate authority or authorities selected to report on.</td></tr>
<tr><td>EndDate</td><td>The end date selected for the reporting period to report on. This is configured as a certain number of days, weeks or months before or after the current date (e.g. 0 days before today—meaning today).</td></tr>
<tr><td>EvalDate</td><td>The evaluation date selected for the reporting period to report on. This is configured as a certain number of days, weeks or months before or after the current date (e.g. 30 days before today).</td></tr>
<tr><td>Metadata</td><td>The custom metadata fields selected to include in the report.</td></tr>
<tr><td>MinCertCount</td><td>The minimum number of certificates that must have been issued for the given template before the template will be included in the report.</td></tr>
<tr><td>OrchestratorPool</td><td>The orchestrator pool selected to report on.</td></tr>
<tr><td>PeriodCount</td><td>The number of days, weeks or months selected to report on.</td></tr>
<tr><td>PeriodSize</td><td>The selected reporting period (day, weeks or months).</td></tr>
<tr><td>Requesters</td><td>The certificate requesters selected to include in the report.</td></tr>
<tr><td>SSHKeyType</td><td>The SSH key type(s) selected to report on.</td></tr>
<tr><td>StartDate</td><td>The start date selected for the reporting period to report on.</td></tr>
</table>
</td></tr>
</table>

Name	In	Description

		<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td>This is configured as a certain number of days, weeks or months before or after the current date (e.g. 30 days before today).</td></tr><tr><td>TemplateIds</td><td>The Keyfactor Command identifiers for the templates to include in the report.</td></tr></table>
		For example:
		<pre>"RuntimeParameters": {
		   "StartDate": "60-Day-Before",
		   "EndDate": "7-Day-Before",
		   "Metadata": "AppOwnerFirstName, AppOwnerLastName",
		   "Requesters": "jsmith"
		}</pre>
		This field is **required** for reports that have runtime parameters.

Table 431: POST Reports {id} Schedules Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>The Keyfactor Command reference ID of the report schedule.</td></tr>
<tr><td>SendReport</td><td>A Boolean indicating whether the report will be sent to the email recipients configured in EmailRecipients (true) or not (false).</td></tr>
<tr><td>SaveReport</td><td>A Boolean indicating whether the report will be saved to the UNC path defined by SaveReportPath (true) or not (false).</td></tr>
<tr><td>SaveReportPath</td><td>A string containing the UNC path to which the report will be written, if configured.</td></tr>
<tr><td>ReportFormat</td><td>A string containing the report format selected for the scheduled report run. Supported values vary depending on the selected report and include:
PDF
Excel
CSV</td></tr>
<tr><td>KeyfactorSchedule</td><td>An array providing the schedule for the report. The schedule can be one of:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
<tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, daily at 11:30 pm:
<pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre></td></tr>
<tr><td>Weekly</td><td>A dictionary that indicates a job scheduled to run on a specific day or days every week at the same time with the parameters:</td></tr>
</table></td></tr>
</table>

Name	Description
	Name / **Description** Monthly: A dictionary that indicates a job scheduled to run on a specific day or days every month at the same time with the parameters:

Name / **Description**

Name	Description
Time	The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).
Days	An array of values representing the days of the week on which to run the job. These can either be entered as integers (0 for Sunday, 1 for Monday, etc.) or as days of the week (e.g. "Sunday").

For example, every Monday, Wednesday and Friday at 5:30 pm:

```
"Weekly": {
   "Days": [
      "Monday",
      "Wednesday",
      "Friday"
   ],
   "Time": "2022-02-27T17:30:00Z"
}
```

Monthly: A dictionary that indicates a job scheduled to run on a specific day or days every month at the same time with the parameters:

Name	Description
Time	The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).
Day	The number of the day, in the month, to run the job.

For example, on the first of every month at 5:30 pm:

```
"Monthly": {
   "Day": 1
   "Time": "2022-02-27T17:30:00Z"
}
```

Note: Although the Swagger *Example Value* may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this

Name	Description
	functionality—are valid for this endpoint.
EmailRecipients	An array containing the email addresses of users configured as recipients of the scheduled report, if any.
RuntimePara-meters	Any array containing the parameters to be used at run time configured in the report schedule. Runtime parameters will vary depending on the report selected. Runtime parameters may include things such as:

Name	Description
CertAuth	The certificate authority or authorities selected to report on.
EndDate	The end date selected for the reporting period to report on. This is configured as a certain number of days, weeks or months before or after the current date (e.g. 0 days before today—meaning today).
EvalDate	The evaluation date selected for the reporting period to report on. This is configured as a certain number of days, weeks or months before or after the current date (e.g. 30 days before today).
Metadata	The custom metadata fields selected to include in the report.
MinCertCount	The minimum number of certificates that must have been issued for the given template before the template will be included in the report.
OrchestratorPool	The orchestrator pool selected to report on.
PeriodCount	The number of days, weeks or months selected to report on.
PeriodSize	The selected reporting period (day, weeks or months).
Requesters	The certificate requesters selected to include in the report.
SSHKeyType	The SSH key type(s) selected to report on.
StartDate	The start date selected for the reporting period to report on. This is configured as a certain number of days, weeks or months before or after the current date (e.g. 30 days before today).
TemplateIds	The Keyfactor Command identifiers for the templates to include in the report.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.21.15 PUT Reports ID Schedules

The PUT /Reports/{id}/Schedules method is used to update the schedule for the built-in report with the specified report ID. This method returns HTTP 200 OK on a success with the details of the report schedule.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
Reports: *Modify*

Table 432: PUT Reports {id} Schedules Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID of the built-in **report** the schedule is associated with. Use the *GET /Reports* method (see GET Reports on page 1513) to retrieve a list of your built-in reports to determine the report ID to use.
Id	Body	**Required**. The Keyfactor Command reference ID of the report **schedule**. Use the *GET /Reports/{id}* (see GET Reports ID on page 1497) to retrieve the details for the desired report to determine the schedule ID to use.
SendReport	Body	A Boolean indicating whether the report will be sent to the email recipients configured in *EmailRecipients* (true) or not (false). The default is *false*.
SaveReport	Body	A Boolean indicating whether the report will be saved to the UNC path defined by *SaveReportPath* (true) or not (false). The default is *false*.
SaveReportPath	Body	**Required***. A string containing the UNC path to which the report will be written, if configured. **Note:** The path for saved reports must be provided in UNC format (\\servername\sharename\path) and must be accessible from the Keyfactor Command administration server. In addition: • Do not use a trailing "\" in the report path. • Ensure that the application pool service account has permission to write to the location where you want the outputted report to be saved. • When scheduling a report, schedule it for at least 10 minutes in advance of the current time if you wish it to run soon. If you want to run it faster than that, the Keyfactor Command Service will need to be restarted. This field is **required** if *SaveReport* is set to *true*.
ReportFormat	Body	**Required**. A string containing the report format selected for the scheduled report run. Supported values vary depending on the selected report and include: • PDF • Excel • CSV
KeyfactorSchedule	Body	**Required**. An array providing the schedule for the report. **Name** / **Description** Off — Turn off a previously configured schedule.

Table 433: PUT Reports {id} Schedules Response Data

Name	Description
Id	The Keyfactor Command reference ID of the report **schedule**.
SendReport	A Boolean indicating whether the report will be sent to the email recipients configured in *EmailRecipients* (true) or not (false).
SaveReport	A Boolean indicating whether the report will be saved to the UNC path defined by *SaveReportPath* (true) or not (false).
SaveReportPath	A string containing the UNC path to which the report will be written, if configured.
ReportFormat	A string containing the report format selected for the scheduled report run. Supported values vary depending on the selected report and include: • PDF • Excel • CSV
KeyfactorSchedule	An array providing the schedule for the report. The schedule can be one of:

Name	Description
Off	Turn off a previously configured schedule.
Daily	A dictionary that indicates a job scheduled to run every day at the same time with the parameter:

Name	Description
Time	The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).

For example, daily at 11:30 pm:

```
"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}
```

Weekly	A dictionary that indicates a job scheduled to run on a specific day or days every week at the same time with the parameters:

Name	Description

	Name / **Description**
	Time — The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).
	Days — An array of values representing the days of the week on which to run the job. These can either be entered as integers (0 for Sunday, 1 for Monday, etc.) or as days of the week (e.g. "Sunday").
	For example, every Monday, Wednesday and Friday at 5:30 pm:
	`"Weekly": { "Days": [ "Monday", "Wednesday", "Friday" ], "Time": "2022-02-27T17:30:00Z" }`
	Monthly — A dictionary that indicates a job scheduled to run on a specific day or days every month at the same time with the parameters:
	Time — The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).
	Day — The number of the day, in the month, to run the job.
	For example, on the first of every month at 5:30 pm:
	`"Monthly": { "Day": 1 "Time": "2022-02-27T17:30:00Z" }`
	Note: Although the Swagger *Example Value* may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this

Name	Description
	functionality—are valid for this endpoint.
EmailRecipients	An array containing the email addresses of users configured as recipients of the scheduled report, if any.
RuntimePara-meters	Any array containing the parameters to be used at run time configured in the report schedule. Runtime parameters will vary depending on the report selected. Runtime parameters may include things such as:

Name	Description
CertAuth	The certificate authority or authorities selected to report on.
EndDate	The end date selected for the reporting period to report on. This is configured as a certain number of days, weeks or months before or after the current date (e.g. 0 days before today—meaning today).
EvalDate	The evaluation date selected for the reporting period to report on. This is configured as a certain number of days, weeks or months before or after the current date (e.g. 30 days before today).
Metadata	The custom metadata fields selected to include in the report.
MinCertCount	The minimum number of certificates that must have been issued for the given template before the template will be included in the report.
OrchestratorPool	The orchestrator pool selected to report on.
PeriodCount	The number of days, weeks or months selected to report on.
PeriodSize	The selected reporting period (day, weeks or months).
Requesters	The certificate requesters selected to include in the report.
SSHKeyType	The SSH key type(s) selected to report on.
StartDate	The start date selected for the reporting period to report on. This is configured as a certain number of days, weeks or months before or after the current date (e.g. 30 days before today).
TemplateIds	The Keyfactor Command identifiers for the templates to include in the report.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.22 Security Identities

The Security Identities component of the Keyfactor API includes methods necessary to list, add, and delete security identities. The permissions set with these methods are used to control access to all aspects of Keyfactor Command.

Table 434: Security Identities Endpoints

Endpoint	Method	Description	Link
/{id}	DELETE	Deletes the security identity with the specified ID.	DELETE Security Identities ID below
/{id}	GET	Returns permission details for the security identity with the specified ID.	GET Security Identities ID on the next page
/Lookup	GET	Validates that the identity with the specified name exists.	GET Security Identities Lookup on page 1550
/	GET	Returns all security identities with filtering and output options.	GET Security Identities on page 1551
/	POST	Adds a new security identity into Keyfactor Command.	POST Security Identities on page 1570

3.2.22.1 DELETE Security Identities ID

The DELETE /Security/Identities/{id} method is used to delete the security identity with the specified ID from Keyfactor Command. Use the *GET /Security/Identities* method (see GET Security Identities on page 1551) to determine the ID of the security identity you wish to delete. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SecuritySettings: *Modify*

Table 435: DELETE Security Identities {id} Input Parameters

Name	In	Description
id	Path	**Required**. The ID of the security identity that should be deleted from Keyfactor Command.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.22.2 GET Security Identities ID

The GET /Security/Identities/{id} method is used to return the security identities configured in Keyfactor Command with the specified ID. This method returns HTTP 200 OK on a success with the details of the security identity's permissions.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SecuritySettings: *Read*

Table 436: GET Security Identities {id} Input Parameters

Name	In	Description
id	Path	**Required**. An integer indicating the Keyfactor Command reference ID of the security identity to retrieve. Use the *GET /Security/Identities* method (see GET Security Identities on page 1551) to retrieve a list of all the security identities to determine the identity's ID.

Table 437: GET Security Identities {id} Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Identity</td><td>A string containing the account name for the security identity. For Active Directory users and groups, this will be in the form DOMAIN\\user or group name. For example:
KEYEXAMPLE\\PKI Administrators</td></tr>
<tr><td>SecuredAreaPermissions</td><td>An object containing a series of arrays with information about the global permissions granted to the security identity. Global permission information includes:
<table><tr><th>Name</th><th>Description</th></tr><tr><td>Permission</td><td>A string indicating the permission granted. In the case of global permissions, this is the name of the role followed by the level of permission granted, the choices for which vary depending on the role.</td></tr><tr><td>GrantedByRoles</td><td>An object containing a list of roles that grant that permission.</td></tr></table>For example:
<pre>"SecuredAreaPermissions": [
   {
      "Permission": "AdminPortal:Read",
      "GrantedByRoles": [
         "Read Only",
         "Staff"
      ]
   },
   {
      "Permission": "Reports:Read",
      "GrantedByRoles": [
         "Read Only"
      ]
   },
]</pre>For more information about global permissions, see the Security Roles and Identities on page 577 page in the Keyfactor Command Reference Guide.</td></tr>
<tr><td>CollectionPermissions</td><td>An object containing information about the certificate collection permissions granted to the security identity. Collection permission information includes:
<table><tr><th>Name</th><th>Description</th></tr><tr><td>Permission</td><td>A string indicating the permission granted. In the case of</td></tr></table></td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>collection permissions, this is the name of the certificate collection followed by the level of permission granted.</td></tr>
<tr><td>GrantedByRoles</td><td>An array containing a list of roles that grant that permission.</td></tr>
</table>
For example:
<pre>
"CollectionPermissions": [
   {
      "Permission": "Issued in the Last Week:Certificates_Read",
      "GrantedByRoles": [
         "Staff",
         "Power Users"
      ]
   },
   {
      "Permission": "Web Server Certs:Certificates_EditMetadata",
         "GrantedByRoles": [
         "Power Users"
      ]
   },
]
</pre>
For more information about collection permissions, see the Certificate Permissions on page 588 page in the Keyfactor Command Reference Guide.
</td></tr>
<tr><td>ContainerPermissions</td><td>
An object containing information about the global permissions granted to the security identity. Container permission information includes:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Permission</td><td>A string indicating the permission granted. In the case of container permissions, this is the name of the certificate store container followed by the level of permission granted (read, schedule or modify).</td></tr>
<tr><td>GrantedByRoles</td><td>An array containing a list of roles that grant that permission.</td></tr>
</table>
For example:
<pre>
"ContainerPermissions": [
   {
      "Permission": "IIS Personal:CertificateStoreManagement_Read",
</pre>
</td></tr>
</table>

Name	Description

	<pre>"GrantedByRoles": [
	"Power Users",
	"Staff"
	]
	},
	{
	"Permission": "F5 SSL Profiles REST:CertificateStoreManagement_
	Schedule",
	"GrantedByRoles": [
	"Power Users"
	]
	},
	]</pre>
	For more information about container permissions, see the Container Permissions on page 591 page in the *Keyfactor Command Reference Guide*.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.22.3 GET Security Identities Lookup

The GET /Security/Identities/Lookup method is used to confirm that the security identity specified is valid for the environment—the Active Directory forest in which Keyfactor Command is installed and any forests in a two-way trust (or one-way trust in a direction that allows the lookup to occur). It can be used to query an identity in the source identity store (Active Directory) to confirm its validity before using *POST /Security/Identities* (see POST Security Identities on page 1570) to create a new identity in Keyfactor Command with that user or group. This method returns HTTP 200 OK on a success with a response of true or false.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SecuritySettings: *Read*

Table 438: GET Security Identities Lookup Input Parameters

Name	In	Description
Name	Query	**Required**. The identity name in the source identity store. For Active Directory users and groups, this can be given either as DOMAIN\name or name@domain.com. For users in the local domain (the domain in which the Keyfactor Command server is installed), the lookup may be done without a domain name.

Table 439: GET Security Identities Lookup Response Data

Name	Description
Valid	A Boolean that indicates whether the provided name is valid (true) or not (false).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.22.4 GET Security Identities

The GET /Security/Identities method is used to return the list of security identities configured in Keyfactor Command. This method returns HTTP 200 OK on a success with the details of the security identities.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SecuritySettings: *Read*

Table 440: GET Security Identities Input Parameters

Name	In	Description
validate	Query	A boolean that specifies whether the optional parameter of *validate* is **false**, which allows the AuditXML validation to be skipped when loading records, or **true** (or not specified) in which case validation will occur. The default is **true**.
queryString		*Not used.*
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *Id*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 441: GET Security Identities Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer containing the Keyfactor Command reference ID for the security identity.</td></tr>
<tr><td>AccountName</td><td>A string containing the account name for the security identity. For Active Directory users and groups, this will be in the form DOMAIN\\user or group name. For example:
KEYEXAMPLE\\PKI Administrators</td></tr>

	],</pre></td></tr></table>

Valid	A Boolean indicating whether the security identity's audit XML is valid (true) or not (false). A security identity may become invalid if Keyfactor Command determines that it appears to have been tampered with.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.22.5 POST Security Identities

The POST /Security/Identities method is used to create a new security identity in Keyfactor Command. Use the *GET /Security/Identities/Lookup* method (see GET Security Identities Lookup on page 1550) before creating the new identity to confirm that the identity you plan to create is valid. This method returns HTTP 200 OK on a success with the details of the new security identity.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SecuritySettings: *Modify*

Tip: This method cannot be used to assign roles to an identity. Use the *PUT /Security/Roles* method (see PUT Security Roles on page 1649) to assign roles to an identity.

Table 442: POST Security Identities Input Parameters

Name	In	Description
AccountName	Body	**Required**. A string containing the account name for the security identity. For Active Directory user and groups, this will be in the form DOMAIN\\user or group name. For example: KEYEXAMPLE\\PKI Administrators

Table 443: POST Security Identities Response Data

Name	Description
Id	An integer containing the Keyfactor Command identifier for the security identity.
AccountName	A string containing the account name for the security identity. For Active Directory user and groups, this will be in the form DOMAIN\\user or group name. For example: `KEYEXAMPLE\\PKI Administrators`
IdentityType	A string indicating the type of identity—User or Group.
Roles	An array containing information about the security roles assigned to the security identity. For new security identities, this will be blank.
Valid	A Boolean that indicates whether the security identity's audit XML is valid (true) or not (false). A security identity may become invalid if Keyfactor Command determines that it appears to have been tampered with.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.23 Security Roles Permissions

The Security Roles Permissions component of the Keyfactor API includes methods necessary to list, add, and update security roles permissions at the role, global, container and collection-level.

Table 444: Security Roles Permissions Endpoints

Endpoint	Method	Description	Link
/{id}/Permisssions	GET	Returns all permissions associated with the security role that matches the id	GET Security Roles ID Permissions on the next page
/{id}/Permisssions/Global	GET	Returns all global permissions associated with the security role that matches the ID.	GET Security Roles ID Permissions Global on page 1574
/{id}/Permisssions/Global	POST	Adds global permissions to the security role that matches the id. Note that the Areas *Certificates* and *CertificateStoreManagement* are reserved for collection and container permissions, respectively.	POST Security Roles ID Permissions Global on page 1575
/{id}/Permisssions/Global	PUT	Sets global permissions of the security role that matches the ID. Note that the Areas *Certificates* and *CertificateStoreManagement* are reserved for collection and container permissions, respectively.	PUT Security Roles ID Permissions Global on page 1595
/{id}/Permisssions/Containers	GET	Returns all container permissions associated with the security role that matches the ID.	GET Security Roles ID Permissions Containers on page 1616
/{id}/Permisssions/Containers	POST	Adds container permissions to the security role that matches the ID.	POST Security Roles ID Permissions Containers on page 1617
/{id}/Permisssions/Containers	PUT	Sets container permissions to the security role that matches the ID.	PUT Security Roles ID Permissions Containers on page 1619
/{id}/Permisssions/Collections	GET	Returns all collection permissions associated with the security role that matches the ID.	GET Security Roles ID Permissions Collections on

Endpoint	Method	Description	Link
			page 1620
/{id}/Permisssions/Collections	POST	Adds collection permissions to the security role that matches the ID.	POST Security Roles ID Permissions Collections on page 1621
/{id}/Permisssions/Collections	PUT	Sets collection permissions to the security role that matches the ID.	PUT Security Roles ID Permissions Collections on page 1622

3.2.23.1 GET Security Roles ID Permissions

The GET /Security/Roles/{id}/Permissions method is used to return all permissions associated with the security role that matches the ID. This method returns HTTP 200 OK on a success with certificate store container permission details for the specified security role.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SecuritySettings: *Read*

Table 445: GET Security Roles {id} Permissions Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID of the security role for which to retrieve permissions. Use the *GET /Security/Roles* method (see GET Security Roles on page 1630) to retrieve a list of all the security roles to determine the role's ID.

Table 446: GET Security Roles {id} Permissions Response Data

Name	Description
	An object containing information about the permissions granted to the security role. Details include: **Name** / **Description** Type — A string containing the area at which the permission is applied to (global, container, or collection). Area — A string containing the name of the permission (e.g. "Certificates"). Permission — A string indicating the permission level granted in the area for this role (e.g. "Read").

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.23.2 GET Security Roles ID Permissions Global

The GET /Security/Roles/{id}/Permissions/Global method is used to return all global permissions associated with the security role that matches the ID. This method returns HTTP 200 OK on a success with certificate store container permission details for the specified security role.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SecuritySettings: *Read*

Table 447: GET Security Roles {id} Global Permissions Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID of the security role for which to retrieve global permissions. Use the *GET /Security/Roles* method (see GET Security Roles on page 1630) to retrieve a list of all the security roles to determine the role's ID.

Table 448: GET Security Roles {id} Global Permissions Response Data

Name	Description
	An object containing information about the global permissions granted to the security role. Details include: **Name** / **Description** Area — A string containing the name of the permission (e.g. "Certificates"). Permission — A string indicating the permission level granted in the area for this role (e.g. "Read").

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.23.3 POST Security Roles ID Permissions Global

The POST /Security/Roles/{id}/Permissions/Global method is used to add global permissions to the security role that matches the ID. This method returns HTTP 200 OK on a success with global permission details for the specified security role.

Important: Only the permission settings included in the command will be affected. Any other permissions settings will not be affected and remain as is.

Note: The API Endpoint utility displays a list of valid global permissions on the endpoint.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SecuritySettings: *Modify*

Table 449: POST Security Roles {id}Global Permissions Input Parameters

<table>

Table 450: POST Security Roles {id} Global Permissions Response Data

Name	Description
	An object containing information about the global permissions granted to the security role. Details include: **Name** / **Description** Area — A string containing the name of the permission (e.g. "Certificates"). Permission — A string indicating the permission level granted in the area for this role (e.g. "Read").

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.23.4 PUT Security Roles ID Permissions Global

The PUT /Security/Roles/{id}/Permissions/Global method is used to update the global permissions granted to the specified security role by ID. Note that the areas *Certificates* and *CertificateStoreManagement* are reserved for collection and container permissions. This method returns HTTP 200 OK on a success with global permission details for the specified security role.

Warning: Any previously defined permissions of the given type (e.g. global) that are not submitted with their full existing data using this method will be cleared of their existing data. Existing data for other types will be retained. When using this method, you should first do a GET to retrieve all the permissions of the given type for the role you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not

changing. If you just wish to add permissions without modifying existing permissions, use the POST method.

Note: The API Endpoint utility displays a list of valid global permissions on the endpoint.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SecuritySettings: *Modify*

Table 451: PUT Security Roles {id}Global Permissions Input Parameters

Table 452: PUT Security Roles {id} Global Permissions Response Data

Name	Description
	An object containing information about the global permissions granted to the security role. Details include: **Name** / **Description** Area — A string containing the name of the permission (e.g. "Certificates"). Permission — A string indicating the permission level granted in the area for this role (e.g. "Read").

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.23.5 GET Security Roles ID Permissions Containers

The GET /Security/Roles/{id}/Permissions/Containers method is used to return all certificate store container permissions associated with the security role that matches the ID. This method returns HTTP 200 OK on a success with certificate store container permission details for the specified security role.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SecuritySettings: *Read*

Table 453: GET Security Roles {id} Permissions Containers Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID of the security role for which to retrieve certificate store container permissions. Use the *GET /Security/Roles* method (see GET Security Roles on page 1630) to retrieve a list of all the security roles to determine the role's ID.

Table 454: GET Security Roles {id} Permissions Containers Response Data

Name	Description
	An object containing information about the certificate store container permissions granted to the security role. Details include: **Name** / **Description** ContainerId — An integer containing the container ID. Name — A string containing the name of the certificate store container. Permission — A string indicating the permission granted on the entity for this role.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.23.6 POST Security Roles ID Permissions Containers

The POST /Security/Roles/{id}/Permissions/Containers method is used to add new container permissions to the security role that matches the ID. This method returns HTTP 200 OK on a success with certificate store container permission details for the specified security role.

Important: Only the permission settings included in the command will be affected. Any other permissions settings will not be affected and remain as is.

Note: The API Endpoint utility displays a list of valid global permissions on the endpoint.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SecuritySettings: *Modify*

Table 455: POST Security Roles {id} Permissions Containers Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID of the security role for which to set certificate store container permissions. Use the *GET /Security/Roles* method (see GET Security Roles on page 1630) to retrieve a list of all the security roles to determine the role's ID.
containerPermissions	Body	An object containing information about the permissions granted to certificate store containers for this security role. Container details include: **Name** / **Description** ContainerId — **Required**. An integer containing the Keyfactor Command identifier for the certificate store container. Permission — **Required**. A string indicating the permission granted on the container for this role—*Read*, *Schedule*, or *Modify*. **Tip:** Users with *Modify* permissions on a container inherit *Read* and *Schedule*; users with *Schedule* permissions on a container inherit *Read*.

Table 456: POST Security Roles {id} Permissions Containers Response Data

Name	Description
	An object containing information about the certificate store container permissions granted to the security role. Details include: **Name** / **Description** ContainerId — An integer containing the container ID. Name — A string containing the name of the certificate store container. Permission — A string indicating the permission granted on the entity for this role.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.23.7 PUT Security Roles ID Permissions Containers

The PUT /Security/Roles/{id}/Permissions/Containers method is used to update container permissions to the security role that matches the ID. This method returns HTTP 200 OK on a success with certificate store container permission details for the specified security role.

Warning: Any previously defined permissions of the given type (e.g. container) that are not submitted with their full existing data using this method will be cleared of their existing data. Existing data for other types will be retained. When using this method, you should first do a GET to retrieve all the permissions of the given type for the role you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing. If you just wish to add permissions without modifying existing permissions, use the POST method.

Note: The API Endpoint utility displays a list of valid global permissions on the endpoint.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SecuritySettings: *Modify*

Table 457: PUT Security Roles {id} Permissions Containers Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID of the security role for which to set certificate store container permissions. Use the *GET /Security/Roles* method (see GET Security Roles on page 1630) to retrieve a list of all the security roles to determine the role's ID.
containerPermissions	Body	An object containing information about the permissions granted to certificate store containers for this security role. Container details include: **Name** / **Description** ContainerId — **Required**. An integer containing the Keyfactor Command identifier for the certificate store container. Permission — **Required**. A string indicating the permission granted on the container for this role—*Read*, *Schedule*, or *Modify*. **Tip:** Users with *Modify* permissions on a container inherit *Read* and *Schedule*; users with *Schedule* permissions on a container inherit *Read*.

Table 458: PUT Security Roles {id} Permissions Containers Response Data

Name	Description
	An object containing information about the certificate store container permissions granted to the security role. Details include: **Name** / **Description** ContainerId — An integer containing the container ID. Name — A string containing the name of the certificate store container. Permission — A string indicating the permission granted on the entity for this role.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.23.8 GET Security Roles ID Permissions Collections

The GET /Security/Roles/{id}/Permissions/Collections method is used to return all certificate collection permissions associated with the security role that matches the ID. This method returns HTTP 200 OK on a success with certificate collection permission details for the specified security role.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SecuritySettings: *Read*

Table 459: GET Security Roles {id} Permissions Collections Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID of the security role for which to retrieve certificate collection permissions. Use the *GET /Security/Roles* method (see GET Security Roles on page 1630) to retrieve a list of all the security roles to determine the role's ID.

Table 460: GET Security Roles {id} Permissions Collections Response Data

Name	Description
	An object containing information about the certificate collection permissions granted to the security role. Details include:

Name	Description
CollectionId	An integer containing the collection ID.
Name	A string containing the name of the certificate collection .
Permission	A string indicating the permission granted on the entity for this role.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.23.9 POST Security Roles ID Permissions Collections

The POST/Security/Roles/{id}/Permissions/Collections method is used to add new collection permissions to the security role that matches the ID. This method returns HTTP 200 OK on a success with certificate collection permission details for the specified security role.

Important: Only the permission settings included in the command will be affected. Any other permissions settings will not be affected and remain as is.

Note: The API Endpoint utility displays a list of valid global permissions on the endpoint.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SecuritySettings: *Modify*

Table 461: POST Security Roles {id} Permissions Collections Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID of the security role for which to set certificate collection permissions. Use the *GET /Security/Roles* method (see GET Security Roles on page 1630) to retrieve a list of all the security roles to determine the role's ID.
collectionPermissions	Body	An object containing information about the permissions granted to certificate collection for this security role. Collection details include: **Name** / **Description** CollectionId — **Required**. An integer containing the Keyfactor Command identifier for the certificate collection. Permission — **Required**. A string indicating the permission granted on the collection for this role—*Read*, *EditMetadata*, *Recover*, *Revoke*, or *Delete*.

Table 462: POST Security Roles {id} Permissions Collections Response Data

Name	Description
	An object containing information about the certificate collection permissions granted to the security role. Details include: **Name** / **Description** CollectionId — An integer containing the collection ID. Name — A string containing the name of the certificate collection . Permission — A string indicating the permission granted on the entity for this role.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.23.10 PUT Security Roles ID Permissions Collections

The PUT /Security/Roles/{id}/Permissions/Collections method is used to update collection permissions to the security role that matches the ID. It replaces the deprecated endpoint: POST /CertificateCollections/{id}/Permissions. This method returns HTTP 200 OK on a success with certificate collection permission details for the specified security role.

Warning: Any previously defined permissions of the given type (e.g. collection) that are not submitted with their full existing data using this method will be cleared of their existing data. Existing data for other types will be retained. When using this method, you should first do a GET to retrieve all the permissions of the given type for the role you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing. If you just wish to add permissions without modifying existing permissions, use the POST method.

Note: The API Endpoint utility displays a list of valid global permissions on the endpoint.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SecuritySettings: *Modify*

Table 463: PUT Security Roles {id} Permissions Collections Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID of the security role for which to set certificate collection permissions. Use the *GET /Security/Roles* method (see GET Security Roles on page 1630) to retrieve a list of all the security roles to determine the role's ID.
collectionPermissions	Body	An object containing information about the permissions granted to certificate collection for this security role. Collection details include: **Name** / **Description** CollectionId — **Required**. An integer containing the Keyfactor Command identifier for the certificate collection. Permission — **Required**. A string indicating the permission granted on the collection for this role—*Read*, *EditMetadata*, *Recover*, *Revoke*, or *Delete*.

Table 464: PUT Security Roles {id} Permissions Collections Response Data

Name	Description
	An object containing information about the certificate collection permissions granted to the security role. Details include: **Name** / **Description** CollectionId / **Required**. An integer containing the collection ID. Name / **Required**. A string containing the name of the certificate collection . Permission / **Required**. A string indicating the permission granted on the entity for this role.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.24 Security Roles

The Security Roles component of the Keyfactor API includes methods necessary to list, add, update, and delete security roles. The permissions set with these methods are used to control access to all aspects of Keyfactor Command.

Table 465: Security Roles Endpoints

Endpoint	Method	Description	Link
/{id}	DELETE	Deletes the security role with the specified ID.	DELETE Security Roles ID below
/{id}	GET	Returns details for the security role with the specified ID, including permissions granted to the role and security identities assigned the role.	GET Security Roles ID on the next page
/{id}/Identities	GET	Returns the security identities assigned to the security role with the specified ID.	GET Security Roles ID Identities on page 1628
/{id}/Identities	PUT	Updates the security identities assigned to the security role with the specified ID.	PUT Security Roles ID Identities on page 1629
/	GET	Returns all security roles with filtering and output options.	GET Security Roles on page 1630
/	POST	Adds a new security role.	POST Security Roles on page 1632
/	PUT	Updates the security role with the specified ID.	PUT Security Roles on page 1649
/{id}/Copy	POST	Adds a new security role by copying the existing security role with the specified ID.	POST Security Roles ID Copy on page 1666

3.2.24.1 DELETE Security Roles ID

The DELETE /Security/Roles/{id} method is used to delete the security role with the specified ID. Use the *GET /Security/Roles* method (see GET Security Roles on page 1630) to determine the ID of the security role you wish to delete. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SecuritySettings: *Modify*

Table 466: DELETE Security Roles {id} Input Parameters

Name	In	Description
id	Path	**Required**. The ID of the security role that should be deleted from Keyfactor Command.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.24.2 GET Security Roles ID

The GET /Security/Roles/{id} method is used to return a security role by ID. This method returns HTTP 200 OK on a success with details for the specified security roles.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SecuritySettings: *Read*

Table 467: GET Security Roles {id} Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID of the security role to retrieve. Use the *GET /Security/Roles* method (see GET Security Roles on page 1630) to retrieve a list of all the security roles to determine the role's ID.

Table 468: GET Security Roles {id} Response Data

Name	Description
Id	An integer containing the Keyfactor Command identifier for the security role.
Name	A string containing the short reference name for the security role.
Description	A string containing the description for the security role.
Enabled	A Boolean that indicates whether the security role is enabled (true) or not (false). Security roles that have been disabled cannot be assigned to security identities. The default is *true*. This is considered deprecated and may be removed in a future release.
Immutable	A Boolean that indicates whether the security role has been marked as editable (true) or not (false). Internal Keyfactor Command roles are not editable. This setting is reserved for Keyfactor Command internal use.
Valid	A Boolean that indicates whether the security role's audit XML is valid (true) or not (false). A security role may become invalid if Keyfactor Command determines that it appears to have been tampered with. This setting is not end-user configurable.
Private	A Boolean that indicates whether the security role has been marked private (true) or not (false). The default is *false*. This is considered deprecated and may be removed in a future release.
Identities	An array containing information about the security identities assigned to the security role. Identity details include: **Name** / **Description** Id — An integer containing the Keyfactor Command identifier for the security identity. AccountName — A string containing the account name for the security identity. For Active Directory users and groups, this will be in the form DOMAIN\\user or group name. For example: `KEYEXAMPLE\\PKI Administrators` IdentityType — A string indicating the type of identity—User or Group. SID — A string containing the security identifier from the source identity store (e.g. Active Directory) for the security identity.
Permissions	An object containing the permissions assigned to the role in a comma-separated list of Name:Value pairs. For example: `"Permissions": [`

Name	Description

	<pre>"AdminPortal:Read",
	"Dashboard:Read"
	],</pre>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.24.3 GET Security Roles ID Identities

The GET /Security/Roles/{id}/Identities method is used to return the security identities assigned to a security role by security role ID. This method returns HTTP 200 OK on a success with details of the security identities assigned to the specified security role.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SecuritySettings: *Read*

Table 469: GET Security Roles {id} Identities Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID of the security role for which to retrieve security identities. Use the *GET /Security/Roles* method (see GET Security Roles on page 1630) to retrieve a list of all the security roles to determine the role's ID.

Table 470: GET Security Roles {id} Identities Response Data

Name	Description
	An array containing information about the security identities assigned to the security role. Identity details include: **Name** / **Description** Id — An integer containing the Keyfactor Command identifier for the security identity. Name — A string containing the account name for the security identity. For Active Directory users and groups, this will be in the form DOMAIN\\user or group name. For example: KEYEXAMPLE\\PKI Administrators

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.24.4 PUT Security Roles ID Identities

The PUT /Security/Roles{id}/Identities method is used to update security identities assigned to a security role in Keyfactor Command. This method returns HTTP 200 OK on a success with the details of the security identities actively assigned to the security role.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SecuritySettings: *Modify*

Table 471: PUT Security Roles {id} Identities Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID of the security role for which to update identities. Use the *GET /Security/Roles* method (see GET Security Roles on the next page) to retrieve a list of all the security roles to determine the role's ID.
identities	Body	An array in which you provide a **complete** list of the identities that are associated with an Security Role Id. Use the *GET /Security/Identities* method (see GET Security Identities on page 1551) to retrieve a list of all the security identities to determine the identity ID(s).

Table 472: PUT Security Roles {id} Identities Response Data

Name	Description
	An array containing information about the security identities assigned to the security role. Identity details include:

Name	Description
Id	An integer containing the Keyfactor Command identifier for the security identity.
Name	A string containing the account name for the security identity. For Active Directory users and groups, this will be in the form DOMAIN\\user or group name. For example: KEYEXAMPLE\\PKI Administrators

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.24.5 GET Security Roles

The GET /Security/Roles method is used to return the list of security roles configured in Keyfactor Command. This method returns HTTP 200 OK on a success with the details of the security roles.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SecuritySettings: *Read*

Table 473: GET Security Roles Input Parameters

Name	In	Description
validate	Query	A boolean that specifies whether the optional parameter of *validate* is **false**, which allows the AuditXML validation to be skipped when loading records, or **true** (or not specified) in which case validation will occur. The default is **true**.
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Using the Security Role Search Feature on page 600. The query fields supported for this endpoint are: • *Name*
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *Name*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 474: GET Security Roles Response Data

Name	Description
Id	An integer containing the Keyfactor Command identifier for the security role.
Name	A string containing the short reference name for the security role.
Description	A string containing the description for the security role.
Enabled	A Boolean that indicates whether the security role is enabled (true) or not (false). Security roles that have been disabled cannot be assigned to security identities. The default is *true*. This is considered deprecated and may be removed in a future release.
Immutable	A Boolean that indicates whether the security role has been marked as editable (true) or not (false). Internal Keyfactor Command roles are not editable. This setting is reserved for Keyfactor Command internal use.
Valid	A Boolean that indicates whether the security role's audit XML is valid (true) or not (false). A security role may become invalid if Keyfactor Command determines that it appears to have been tampered with. This setting is not end-user configurable.
Private	A Boolean that indicates whether the security role has been marked private (true) or not (false). The default is *false*. This is considered deprecated and may be removed in a future release.
Identities	An array containing information about the security identities assigned to the security role. Identity details include: **Name** / **Description** Id — An integer containing the Keyfactor Command identifier for the security identity. AccountName — A string containing the account name for the security identity. For Active Directory users and groups, this will be in the form DOMAIN\\user or group name. For example: `KEYEXAMPLE\\PKI Administrators` IdentityType — A string indicating the type of identity—User or Group. SID — A string containing the security identifier from the source identity store (e.g. Active Directory) for the security identity.
Permissions	An object containing the permissions assigned to the role in a comma-separated list of Name:Value pairs. For example: `"Permissions": [`

Name	Description

	<pre>"AdminPortal:Read",
	"Dashboard:Read"
	],</pre>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.24.6 POST Security Roles

The POST /Security/Roles method is used to create a new security role in Keyfactor Command. This method returns HTTP 200 OK on a success with the details of the security role.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SecuritySettings: *Modify*

Table 475: POST Security Roles Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>

		<pre>"Identities": [
		  {
		  "Name": "KEYEXAMPLE\\jsmith"
		  },
		  {
		  "Name": "KEYEXAMPLE\\mjones"
		  }
		]</pre>

Table 476: POST Security Roles Response Data

Name	Description
Id	An integer containing the Keyfactor Command identifier for the security role.
Name	A string containing the short reference name for the security role.
Description	A string containing the description for the security role.
Enabled	A Boolean that indicates whether the security role is enabled (true) or not (false). Security roles that have been disabled cannot be assigned to security identities. The default is *true*. This is considered deprecated and may be removed in a future release.
Immutable	A Boolean that indicates whether the security role has been marked as editable (true) or not (false). Internal Keyfactor Command roles are not editable. This setting is reserved for Keyfactor Command internal use.
Valid	A Boolean that indicates whether the security role's audit XML is valid (true) or not (false). A security role may become invalid if Keyfactor Command determines that it appears to have been tampered with. This setting is not end-user configurable.
Private	A Boolean that indicates whether the security role has been marked private (true) or not (false). The default is *false*. This is considered deprecated and may be removed in a future release.
Identities	An array containing information about the security identities assigned to the security role. Identity details include: **Name** / **Description** Id — An integer containing the Keyfactor Command identifier for the security identity. AccountName — A string containing the account name for the security identity. For Active Directory users and groups, this will be in the form DOMAIN\\user or group name. For example: `KEYEXAMPLE\\PKI Administrators` IdentityType — A string indicating the type of identity—User or Group. SID — A string containing the security identifier from the source identity store (e.g. Active Directory) for the security identity.
Permissions	An object containing the permissions assigned to the role in a comma-separated list of Name:Value pairs. For example: `"Permissions": [`

Name	Description

	<pre>"AdminPortal:Read",
	"Dashboard:Read"
	],</pre>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.24.7 PUT Security Roles

The PUT /Security/Roles method is used to update a security role in Keyfactor Command including the permissions set for the role and the security identities mapped to the role. This method returns HTTP 200 OK on a success with the details of the security role.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SecuritySettings: *Modify*

Warning: Any previously populated fields that are not submitted with their full existing data using this method will be cleared of their existing data. When using this method, you should first do a GET to retrieve all the values for the record you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing.

Table 477: PUT Security Roles Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>

Table 478: PUT Security Roles Response Data

Name	Description
Id	An integer containing the Keyfactor Command identifier for the security role.
Name	A string containing the short reference name for the security role.
Description	A string containing the description for the security role.
Enabled	A Boolean that indicates whether the security role is enabled (true) or not (false). Security roles that have been disabled cannot be assigned to security identities. The default is *true*. This is considered deprecated and may be removed in a future release.
Immutable	A Boolean that indicates whether the security role has been marked as editable (true) or not (false). Internal Keyfactor Command roles are not editable. This setting is reserved for Keyfactor Command internal use.
Valid	A Boolean that indicates whether the security role's audit XML is valid (true) or not (false). A security role may become invalid if Keyfactor Command determines that it appears to have been tampered with. This setting is not end-user configurable.
Private	A Boolean that indicates whether the security role has been marked private (true) or not (false). The default is *false*. This is considered deprecated and may be removed in a future release.
Identities	An array containing information about the security identities assigned to the security role. Identity details include: **Name** / **Description** Id — An integer containing the Keyfactor Command identifier for the security identity. AccountName — A string containing the account name for the security identity. For Active Directory users and groups, this will be in the form DOMAIN\\user or group name. For example: `KEYEXAMPLE\\PKI Administrators` IdentityType — A string indicating the type of identity—User or Group. SID — A string containing the security identifier from the source identity store (e.g. Active Directory) for the security identity.
Permissions	An object containing the permissions assigned to the role in a comma-separated list of Name:Value pairs. For example: `"Permissions": [`

Name	Description

	<pre>"AdminPortal:Read",

	],</pre>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.24.8 POST Security Roles ID Copy

The POST /Security/Roles{id}/Copy method is used to copy an existing security role in Keyfactor Command to create a new security role. This method returns HTTP 200 OK on a success with the details of the new security role.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SecuritySettings: *Modify*

Table 479: POST Security Roles {id} Copy Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID of the security role from which to copy role information. Use the *GET /Security/Roles* method (see GET Security Roles on page 1630) to retrieve a list of all the security roles to determine the role's ID.
role	Body	An array containing information about the new security role to create. Role details include: **Name** — **Description** Name — **Required**. A string containing the short reference name for the security role. Description — **Required**. A string containing the description for the security role.

Table 480: POST Security Roles {id} Copy Response Data

Name	Description
Id	An integer containing the Keyfactor Command identifier for the security role.
Name	A string containing the short reference name for the security role.
Description	A string containing the description for the security role.
Enabled	A Boolean that indicates whether the security role is enabled (true) or not (false). Security roles that have been disabled cannot be assigned to security identities. The default is *true*. This is considered deprecated and may be removed in a future release.
Immutable	A Boolean that indicates whether the security role has been marked as editable (true) or not (false). Internal Keyfactor Command roles are not editable. This setting is reserved for Keyfactor Command internal use.
Valid	A Boolean that indicates whether the security role's audit XML is valid (true) or not (false). A security role may become invalid if Keyfactor Command determines that it appears to have been tampered with. This setting is not end-user configurable.
Private	A Boolean that indicates whether the security role has been marked private (true) or not (false). The default is *false*. This is considered deprecated and may be removed in a future release.
Identities	An array containing information about the security identities assigned to the security role. Identity details include: **Name** / **Description** Id — An integer containing the Keyfactor Command identifier for the security identity. AccountName — A string containing the account name for the security identity. For Active Directory users and groups, this will be in the form DOMAIN\\user or group name. For example: `KEYEXAMPLE\\PKI Administrators` IdentityType — A string indicating the type of identity—User or Group. SID — A string containing the security identifier from the source identity store (e.g. Active Directory) for the security identity.
Permissions	An object containing the permissions assigned to the role in a comma-separated list of Name:Value pairs. For example: `"Permissions": [`

Name	Description

	<pre>"AdminPortal:Read",

3.2.25 SSH

The SSH component of the Keyfactor Web APIs includes methods necessary to create, update, and delete SSH keys, logons, servers, server groups, and service accounts within Keyfactor Command.

Table 481: SSH Endpoints

Endpoint	Method	Description	Link
/Keys/Unmanaged/{id}	DELETE	Delete a discovered unmanaged SSH key for the specified ID.	DELETE SSH Keys Unmanaged ID on page 1672
/Keys/Unmanaged/{id}	GET	Retrieve details for a discovered unmanaged SSH key for the specified ID.	GET SSH Keys Unmanaged ID on page 1673
/Keys/MyKey	GET	Retrieve details for a user's SSH key generated through Keyfactor Command.	GET SSH Keys My Key on page 1674
/Keys/MyKey	POST	Generate a new SSH key pair for a user through Keyfactor Command.	POST SSH Keys My Key on page 1677
/Keys/MyKey	PUT	Update an SSH key for a user through Keyfactor Command.	PUT SSH Keys My Key on page 1681
/Keys/Unmanaged	DELETE	Delete one or more discovered unmanaged SSH keys based on a selection query.	DELETE SSH Keys Unmanaged on page 1682
/Keys/Unmanaged	GET	Retrieve details for one or more discovered unmanaged SSH keys based on a selection query.	GET SSH Keys Unmanaged on page 1683

Endpoint	Method	Description	Link
/Logons/{id}	DELETE	Deletes a Linux logon from Keyfactor Command.	DELETE SSH Logons ID on page 1686
/Logons/{id}	GET	Returns information about a Linux logons.	GET SSH Logons ID on page 1687
/Logons/	GET	Returns information about one or more Linux logons.	GET SSH Logons on page 1689
/Logons/	POST	Creates a new Linux logon in Keyfactor Command and, for servers in *inventory and publish policy* mode, publishes it out to a Linux server.	POST SSH Logons on page 1690
/Logons/Access	POST	Maps users and service accounts with a Linux logon to associate the SSH keys of the users with the Linux logon.	POST SSH Logons Access on page 1693
/Servers/{id}	DELETE	Deletes the SSH server with the specified ID.	DELETE SSH Servers ID on page 1695
/Servers/{id}	GET	Returns the SSH server with the specified ID.	GET SSH Servers ID on page 1695
/Servers/Access/{id}	GET	Retrieves Linux logons along with users and service accounts granted access to those logons for the specified SSH server.	GET SSH Servers Access ID on page 1700
/Servers/	GET	Returns a list of a SSH servers configured in Keyfactor Command.	GET SSH Servers on page 1702
/Servers/	POST	Creates a new SSH server.	POST SSH Servers on page 1706
/Servers/	PUT	Updates an existing SSH server.	PUT SSH Servers on page 1711
/Servers/Access	DELETE	Deletes Linux logon to user and service account mappings for an SSH server.	DELETE SSH Servers Access on page 1716
/Servers/Access	POST	Creates Linux logon to user and service account mappings for an SSH server.	POST SSH Servers Access on page 1718

Endpoint	Method	Description	Link
/ServerGroups/{id}	DELETE	Deletes the SSH server group with the specified ID.	DELETE SSH Server Groups ID on page 1721
/ServerGroups/{id}	GET	Returns the SSH server group with the specified ID.	GET SSH Server Groups ID on page 1722
/ServerGroups/{name}	GET	Returns the SSH server group with the specified name.	GET SSH Server Groups Name on page 1726
/ServerGroups/Access/{id}	GET	Retrieves Linux logons along with users and service accounts granted access to those logons for the specified SSH server group.	GET SSH Server Groups Access ID on page 1730
/ServerGroups/	GET	Returns a list of a SSH server groups configured in Keyfactor Command.	GET SSH Server Groups on page 1731
/ServerGroups/	POST	Creates a new SSH server group.	POST SSH Server Groups on page 1736
/ServerGroups/	PUT	Updates an existing SSH server group.	PUT SSH Server Groups on page 1743
/ServerGroups/Access	DELETE	Deletes Linux logon to user and service account mappings for an SSH server group.	DELETE SSH Server Groups Access on page 1750
/ServerGroups/Access	POST	Creates Linux logon to user and service account mappings for an SSH server group.	POST SSH Server Groups Access on page 1751
/ServiceAccounts/{id}	DELETE	Deletes the SSH service account with the specified ID.	DELETE SSH Service Accounts ID on page 1754
/ServiceAccounts/{id}	GET	Returns the SSH service account with the specified ID.	GET SSH Service Accounts ID on page 1756
/ServiceAccounts/Key/{id}	GET	Returns the public key and optional private key	GET SSH Service

Endpoint	Method	Description	Link
		of an SSH service account with the specified ID.	Accounts Key ID on page 1762
/ServiceAccounts/	DELETE	Deletes one or more SSH service accounts with the specified IDs.	DELETE SSH Service Accounts on page 1766
/ServiceAccounts/	GET	Returns a list of SSH service accounts based on the specified filters.	GET SSH Service Accounts on page 1768
/ServiceAccounts/	POST	Creates a new SSH service account.	POST SSH Service Accounts on page 1775
/ServiceAccounts/	PUT	Updates an existing SSH service account.	PUT SSH Service Accounts on page 1784
/ServiceAccounts/Rotate/{id}	POST	Generates a new key pair for an existing service account.	POST SSH Service Accounts Rotate ID on page 1791
/Users/{id}	DELETE	Deletes the SSH user with the specified ID.	DELETE SSH Users ID on page 1795
/Users/{id}	GET	Returns the SSH user with the specified ID.	GET SSH Users ID on page 1795
/Users/	GET	Returns a list of SSH users based on the specified filters.	GET SSH Users on page 1800
/Users/	POST	Creates a new SSH user.	POST SSH Users on page 1809
/Users/	PUT	Updates an existing SSH user.	PUT SSH Users on page 1810
/Users/Access	POST	Creates a mapping from the SSH user to one or more Linux logons.	POST SSH Users Access on page 1812

3.2.25.1 SSH Keys

The SSH Keys component of the Keyfactor Web APIs includes methods necessary to allow a user with the *SSH User* Keyfactor Command role permission (see SSH Permissions on page 549 in the *Keyfactor Command Reference*

Guide) to generate an SSH key pair for himself or herself, retrieve that key, update it, or delete it. Methods are also included to list and delete unmanaged keys—keys discovered on servers configured in inventory only mode.

Table 482: SSH Keys Endpoints

Endpoint	Method	Description	Link
/Unmanaged/{id}	DELETE	Delete a discovered unmanaged SSH key for the specified ID.	DELETE SSH Keys Unmanaged ID below
/Unmanaged/{id}	GET	Retrieve details for a discovered unmanaged SSH key for the specified ID.	GET SSH Keys Unmanaged ID on the next page
/MyKey	GET	Retrieve details for a user's SSH key generated through Keyfactor Command.	GET SSH Keys My Key on page 1674
/MyKey	POST	Generate a new SSH key pair for a user through Keyfactor Command.	POST SSH Keys My Key on page 1677
/MyKey	PUT	Update an SSH key for a user through Keyfactor Command.	PUT SSH Keys My Key on page 1681
Unmanaged	DELETE	Delete one or more discovered unmanaged SSH keys based on a selection query.	DELETE SSH Keys Unmanaged on page 1682
Unmanaged	GET	Retrieve details for one or more discovered unmanaged SSH keys based on a selection query.	GET SSH Keys Unmanaged on page 1683

DELETE SSH Keys Unmanaged ID

The DELETE /SSH/Keys/Unmanaged/{id} method is used to delete an unmanaged SSH key by ID. Keys discovered on SSH servers during inventory and discovery are considered unmanaged. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group with which the key is associated and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Note: Deleting an unmanaged key when the associated server is still in inventory only mode will not delete the key on the target server. The next time the server is scanned, the key will re-appear in Keyfactor Command. See Unmanaged SSH Keys on page 508 in the *Keyfactor Command Reference Guide* for more information.

Table 483: DELETE SSH Keys Unmanaged {id} Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID for the unmanaged SSH key to be deleted. Use the *GET /SSH/Keys/Unmanaged* method (see GET SSH Keys Unmanaged on page 1683) to retrieve a list of all the unmanaged keys to determine the unmanaged key's ID.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

GET SSH Keys Unmanaged ID

The GET /SSH/Keys/Unmanaged/{id} method is used to retrieve an unmanaged SSH key by ID. Keys discovered on SSH servers during inventory and discovery are considered unmanaged. This method returns HTTP 200 OK on a success with details for the requested SSH key.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group with which the key is associated and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 484: GET SSH Keys Unmanaged {id} Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID for the unmanaged SSH key to be retrieved. Use the *GET /SSH/Keys/Unmanaged* method (see GET SSH Keys Unmanaged on page 1683) to retrieve a list of all the unmanaged keys to determine the unmanaged key's ID.

Table 485: GET SSH Keys Unmanaged {id} Response Data

Name	Description
ID	An integer indicating the Keyfactor Command reference ID for the SSH key.
Fingerprint	A string indicating the fingerprint of the public key. Each SSH public key has a single cryptographic fingerprint that can be used to uniquely identify the key.
PublicKey	A string indicating the public key of the key pair.
KeyType	A string indicating the cryptographic algorithm used to generate the SSH key. Possible values are: • RSA • ECDSA • Ed25519
KeyLength	An integer indicating the key length for the SSH key. The key length supported depends on the key type selected. Keyfactor Command supports 256 bits for Ed25519 and ECDSA and 2048 or 4096 bits for RSA.
DiscoveredDate	The date, in UTC, on which the SSH key was discovered.
Comments	An array containing one or more strings with the user-defined descriptive comments, if any, on the key. Although entry of an email address in the comment field of an SSH key is traditional, this is not a required format. The comment may can contain any characters supported for string fields, including spaces and most punctuation marks. A key may appear with more than one comment if the originating authorized_keys file contained more than one comment.
LogonCount	An integer indicating the number of Linux logons associated with the SSH key.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

GET SSH Keys My Key

The GET /SSH/Keys/MyKey method is used to retrieve the current user's SSH key generated in Keyfactor Command (see POST SSH Keys My Key on page 1677). This method returns HTTP 200 OK on a success with the key's details.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *User* OR
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

Table 486: GET SSH Keys My Key Input Parameters

Name	In	Description
includePrivateKey	Query	A Boolean that sets whether to include the private key of the SSH key pair in the response (true) or not (false). If set to *true*, the *x-keyfactor-key-passphrase* header must be supplied. The default is *false*.
x-keyfactor-key-pass-phrase	Header	**Required***. A string that sets a password used to secure the private key of the SSH key pair for download. This field is **required** if *IncludePrivateKey* is set to *true*. **Tip:** This password does not need to match the password entered to secure the private key when the SSH key pair was initially generated. The private key is encrypted at download time and a different password may be used for each download.

Table 487: GET SSH Keys My Key Response Data

Name	Description
ID	The Keyfactor Command reference ID for the user's SSH key pair.
Fingerprint	A string indicating the fingerprint of the public key. Each SSH public key has a single cryptographic fingerprint that can be used to uniquely identify the key.
PublicKey	A string indicating the public key of the key pair.
PrivateKey	A string indicating the private key of the key pair.
KeyType	A string indicating the cryptographic algorithm used to generate the SSH key pair. Possible values are: • RSA • ECDSA • Ed25519
KeyLength	An integer indicating the key length for the SSH key. The key length supported depends on the key type selected. Keyfactor Command supports 256 bits for Ed25519 and ECDSA and 2048 or 4096 bits for RSA.
CreationDate	The date, in UTC, on which the SSH key pair was created.
StaleDate	The date, in UTC, on which the SSH key pair will be considered to have reached the end of its lifetime. By default, the lifetime of an SSH key pair is 365 days. The SSH lifetime is defined by the *Key Lifetime (days)* application setting. See in the *Keyfactor Command Reference Guide* for more information.
Email	A string containing the email address of the user who requested the key. This email address is used to alert the user when the key pair is approaching the end of its lifetime.
Comments	An array containing one or more strings with the user-defined descriptive comments, if any, on the key. Although entry of an email address in the comment field of an SSH key is traditional, this is not a required format. The comment may can contain any characters supported for string fields, including spaces and most punctuation marks. Keys created through the Keyfactor Command My SSH Key portal or with the POST /SSH/Keys/MyKey method will contain only one string in the array.
LogonCount	An integer indicating the number of Linux logons associated with the SSH key pair.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

POST SSH Keys My Key

The POST /SSH/Keys/MyKey method is used to generate a new SSH key pair for the current user in Keyfactor Command. The user needs to download the private key as an encrypted file and store it locally and an administrator needs to use Keyfactor Command to associate the user's Keyfactor user account with his or her Linux logon account(s) on the target server(s) that the user wishes to access via SSH (see POST SSH Logons Access on page 1693, POST SSH Server Groups Access on page 1751, and POST SSH Servers Access on page 1718). This method returns HTTP 200 OK on a success with the key's details.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *User* OR
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

Table 488: POST SSH Keys My Key Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>KeyType</td><td>Body</td><td>Required. A string indicating the cryptographic algorithm to use to generate the SSH key. Possible values are:<table><tr><th>Numeric Value</th><th>Text Value</th></tr><tr><td>1</td><td>ECDSA</td></tr><tr><td>2</td><td>Ed25519</td></tr><tr><td>3</td><td>RSA</td></tr></table>The KeyType may be specified using either the numeric value or text value.</td></tr>
<tr><td>PrivateKeyFormat</td><td>Body</td><td>Required. A string indicating the format to use for the downloadable private key. Possible values are:<table><tr><th>Numeric Value</th><th>Text Value</th></tr><tr><td>1</td><td>OpenSSH</td></tr><tr><td>2</td><td>PKCS8</td></tr></table>The PrivateKeyFormat may be specified using either the numeric value or text value.</td></tr>
<tr><td>KeyLength</td><td>Body</td><td>Required*. An integer indicating the key length for the SSH key. The key length supported depends on the key type selected. Keyfactor Command supports 256 bits for Ed25519 and ECDSA and 2048 or 4096 bits for RSA. This field is optional if the KeyType is set to ECDSA or Ed25519 and required if the KeyType is set to RSA.</td></tr>
<tr><td>Email</td><td>Body</td><td>Required. A string containing the email address of the user who requested the key. This email address is used to alert the user when the key pair is approaching the end of its lifetime.</td></tr>
<tr><td>Password</td><td>Body</td><td>Required. A string that sets a password used to secure the private key of the SSH key pair for download.
Tip: This password is used to secure the private key in the downloaded copy of the SSH key pair. You may later download the SSH key pair with private key (see GET SSH Keys My Key on page 1674) and encrypt it with a different password, if desired.</td></tr>
<tr><td>Comment</td><td>Body</td><td>An array containing one or more strings with the user-defined descriptive comments, if any, on the key. Although entry of an email address in the comment</td></tr>
</table>

Name	In	Description
		field of an SSH key is traditional, this is not a required format. The comment may can contain any characters supported for string fields, including spaces and most punctuation marks. **Note:** Although this field is actually an array, entry of only a single comment string is supported. The field is defined as an array to support multiple comments on existing SSH keys found on servers during inventory and discovery.

Table 489: POST SSH Keys My Key Response Data

Name	Description
ID	The Keyfactor Command reference ID for the user's SSH key pair.
Fingerprint	A string indicating the fingerprint of the public key. Each SSH public key has a single cryptographic fingerprint that can be used to uniquely identify the key.
PublicKey	A string indicating the public key of the key pair.
PrivateKey	A string indicating the private key of the key pair.
KeyType	A string indicating the cryptographic algorithm used to generate the SSH key pair. Possible values are: • RSA • ECDSA • Ed25519
KeyLength	An integer indicating the key length for the SSH key. The key length supported depends on the key type selected. Keyfactor Command supports 256 bits for Ed25519 and ECDSA and 2048 or 4096 bits for RSA.
CreationDate	The date, in UTC, on which the SSH key pair was created.
StaleDate	The date, in UTC, on which the SSH key pair will be considered to have reached the end of its lifetime. By default, the lifetime of an SSH key pair is 365 days. The SSH lifetime is defined by the *Key Lifetime (days)* application setting. See in the *Keyfactor Command Reference Guide* for more information.
Email	A string containing the email address of the user who requested the key. This email address is used to alert the user when the key pair is approaching the end of its lifetime.
Comments	An array containing one or more strings with the user-defined descriptive comments, if any, on the key. Although entry of an email address in the comment field of an SSH key is traditional, this is not a required format. The comment may can contain any characters supported for string fields, including spaces and most punctuation marks. Keys created through the Keyfactor Command My SSH Key portal or with the POST /SSH/Keys/MyKey method will contain only one string in the array.
LogonCount	An integer indicating the number of Linux logons associated with the SSH key pair.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

PUT SSH Keys My Key

The PUT /SSH/Keys/MyKey method is used to update the existing SSH key pair for the current user in Keyfactor Command. Most features of a key pair are fixed and cannot be changed. Only the email address and comment associated with the key may be changed with this option. This method returns HTTP 200 OK on a success with the key's details.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *User* OR
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

Warning: Any previously populated fields that are not submitted with their full existing data using this method will be cleared of their existing data. When using this method, you should first do a GET to retrieve all the values for the record you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing.

Table 490: PUT SSH Keys My Key Input Parameters

Name	In	Description
ID	Body	**Required**. The Keyfactor Command reference ID for the SSH key.
Email	Body	**Required**. A string containing the email address of the user who requested the key. This email address is used to alert the user when the key pair is approaching the end of its life-time.
Comment	Body	An array containing one or more strings with the user-defined descriptive comments, if any, on the key. Although entry of an email address in the comment field of an SSH key is traditional, this is not a required format. The comment may can contain any characters supported for string fields, including spaces and most punctuation marks. **Note:** Although this field is actually an array, entry of only a single comment string is supported. The field is defined as an array to support multiple comments on existing SSH keys found on servers during inventory and discovery.

Table 491: PUT SSH Keys My Key Response Data

Name	Description
ID	The Keyfactor Command reference ID for the user's SSH key pair.
Fingerprint	A string indicating the fingerprint of the public key. Each SSH public key has a single cryptographic fingerprint that can be used to uniquely identify the key.
PublicKey	A string indicating the public key of the key pair.
KeyType	A string indicating the cryptographic algorithm used to generate the SSH key pair. Possible values are: • RSA • ECDSA • Ed25519
KeyLength	An integer indicating the key length for the SSH key. The key length supported depends on the key type selected. Keyfactor Command supports 256 bits for Ed25519 and ECDSA and 2048 or 4096 bits for RSA.
CreationDate	The date, in UTC, on which the SSH key pair was created.
StaleDate	The date, in UTC, on which the SSH key pair will be considered to have reached the end of its lifetime. By default, the lifetime of an SSH key pair is 365 days. The SSH lifetime is defined by the *Key Lifetime (days)* application setting. See Application Settings: SSH Tab on page 572 in the *Keyfactor Command Reference Guide* for more information.
Email	A string containing the email address of the user who requested the key. This email address is used to alert the user when the key pair is approaching the end of its lifetime.
Comments	An array containing one or more strings with the user-defined descriptive comments, if any, on the key. Although entry of an email address in the comment field of an SSH key is traditional, this is not a required format. The comment may can contain any characters supported for string fields, including spaces and most punctuation marks. Keys created through the Keyfactor Command My SSH Key portal or with the POST /SSH/Keys/MyKey method will contain only one string in the array.
LogonCount	An integer indicating the number of Linux logons associated with the SSH key pair.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

DELETE SSH Keys Unmanaged

The DELETE /SSH/Keys/Unmanaged method is used to delete one or more unmanaged SSH keys. Keys discovered on SSH servers during inventory and discovery are considered unmanaged. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group with which the key is associated and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Note: Deleting an unmanaged key when the associated server is still in inventory only mode will not delete the key on the target server. The next time the server is scanned, the key will re-appear in Keyfactor Command. See Unmanaged SSH Keys on page 508 in the *Keyfactor Command Reference Guide* for more information.

Table 492: DELETE SSH Keys Unmanaged Input Parameters

Name	In	Description
ids	Body	**Required**. An array of the Keyfactor Command reference IDs for the unmanaged SSH keys to be deleted provided in the request body in the following format (without parameter name): `[4,27,89]` Use the *GET /SSH/Keys/Unmanaged* method (see GET SSH Keys Unmanaged below) to retrieve a list of all the unmanaged keys to determine the unmanaged key IDs.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

GET SSH Keys Unmanaged

The GET /SSH/Keys/Unmanaged method is used to retrieve one or more unmanaged SSH keys. Keys discovered on SSH servers during inventory and discovery are considered unmanaged. Results can be limited to selected keys using filtering, and URL parameters can be used to specify paging and the level of information detail. This method returns HTTP 200 OK on a success with details for the requested SSH keys.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group with which the key is associated and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 493: GET SSH Keys Unmanaged Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Using the Unmanaged Keys Search on page 510. The query fields supported for this endpoint are: • *DiscoveredDate* • *KeyComments* • *KeyLength* • *KeyType* • *ServerId*
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 494: GET SSH Keys Unmanaged Response Data

Name	Description
ID	An integer indicating the Keyfactor Command reference ID for the SSH key.
Fingerprint	A string indicating the fingerprint of the public key. Each SSH public key has a single cryptographic fingerprint that can be used to uniquely identify the key.
PublicKey	A string indicating the public key of the key pair.
KeyType	A string indicating the cryptographic algorithm used to generate the SSH key. Possible values are: • RSA • ECDSA • Ed25519
KeyLength	An integer indicating the key length for the SSH key. The key length supported depends on the key type selected. Keyfactor Command supports 256 bits for Ed25519 and ECDSA and 2048 or 4096 bits for RSA.
DiscoveredDate	The date, in UTC, on which the SSH key was discovered.
Comments	An array containing one or more strings with the user-defined descriptive comments, if any, on the key. Although entry of an email address in the comment field of an SSH key is traditional, this is not a required format. The comment may can contain any characters supported for string fields, including spaces and most punctuation marks. A key may appear with more than one comment if the originating authorized_keys file contained more than one comment.
LogonCount	An integer indicating the number of Linux logons associated with the SSH key.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.25.2 SSH Logons

The SSH Logons component of the Keyfactor Web APIs includes methods necessary to view and manage the Linux user accounts associated with authorized_keys files containing valid SSH public keys. The logons include both those discovered on SSH servers during the initial discovery phase using the orchestrator and those created in Keyfactor Command and published to the SSH servers using the orchestrator.

Table 495: SSH Logon Endpoints

Endpoint	Method	Description	Link
/{id}	DELETE	Deletes a Linux logon from Keyfactor Command.	DELETE SSH

Endpoint	Method	Description	Link
			Logons ID on the next page
/{id}	GET	Returns information about a Linux logons.	GET SSH Logons ID on the next page
/	GET	Returns information about one or more Linux logons.	GET SSH Logons on page 1689
/	POST	Creates a new Linux logon in Keyfactor Command and, for servers in *inventory and publish policy* mode, publishes it out to a Linux server.	POST SSH Logons on page 1690
/Access	POST	Maps users and service accounts with a Linux logon to associate the SSH keys of the users with the Linux logon.	POST SSH Logons Access on page 1693

DELETE SSH Logons ID

The DELETE /SSH/Logons/{id} method is used to delete a Linux logon in Keyfactor Command. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group to which the server on which the logon exists belongs and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Note: Deleting a logon in Keyfactor Command does not delete it on the Linux server. It must be manually removed from the Linux server at the same time. If this is not done, when the next inventory of the Linux server is performed, the logon will be recreated in Keyfactor Command. This method is intended primarily to be used to clean up logons in Keyfactor Command from SSH servers that have been retired.

Table 496: DELETE SSH Logons {id} Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID for the SSH logon to be deleted. Use the *GET /SSH/Logons* method (see GET SSH Logons on page 1689) to retrieve a list of all the SSH logons to determine the logon's ID.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

GET SSH Logons ID

The GET /SSH/Logons/{id} method is used to retrieve a Linux logon by ID. This method returns HTTP 200 OK on a success with details for the requested SSH logon.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group to which the server on which the logon exists belongs and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 497: GET SSH Logons {id} Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID for the SSH logon to retrieve. Use the *GET /SSH/Logons* method (see GET SSH Logons on page 1689) to retrieve a list of all the SSH logons to determine the logon's ID.

Table 498: GET SSH Keys Unmanaged {id} Response Data

Name	Description
ID	An integer indicating the Keyfactor Command reference ID for the SSH logon.
Username	A string indicating the user's logon name on the Linux server.
Server	Details about the server on which the SSH logon resides. Server information includes: **Name** / **Description** Id — An integer indicating the Keyfactor Command reference ID of the server on which the SSH logon resides. Hostname — A string indicating the hostname of the SSH server on which the SSH logon resides. See SSH Servers on page 529 in the *Keyfactor Command Reference Guide* for more information. UnderManagement — A Boolean indicating whether the server on which the SSH logon resides is in *inventory only* mode (false) or *inventory and publish policy* mode (true). GroupName — A string indicating the server group to which the server referenced by *Hostname* belongs. See SSH Server Groups on page 513 in the *Keyfactor Command Reference Guide* for more information.
KeyCount	An integer indicating the number of SSH keys associated with the Linux logons.
Access	An array of key/value pairs providing information about the users mapped to the logon. Access information includes: **Name** / **Description** Id — An integer indicating the Keyfactor Command reference ID of a *user* or *service account* that has been associated with the logon. See SSH on page 479 in the *Keyfactor Command Reference Guide* for more information. Username — A string indicating the username of a *user* (in DOMAIN\\username format) or *service account* (in username@hostname format) that has been associated with the logon.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

GET SSH Logons

The GET /SSH/Logons method is used to retrieve one or more Linux logons. Results can be limited to selected logons using filtering, and URL parameters can be used to specify paging and the level of information detail. This method returns HTTP 200 OK on a success with details for the requested SSH logons.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group to which the server on which the logon exists belongs and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 499: GET SSH Logons Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Using the Logons Search on page 542. The query fields supported for this endpoint are: • *Id* (Login ID) • *LastLogon* • *Hostname* (Logon Server Name) • *LogonUserUsername* • *ServerId* • *UnmanagedKeyId* • *Username*
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *Username*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 500: GET SSH Logons Response Data

Name	Description
ID	An integer indicating the Keyfactor Command reference ID for the SSH logon.
Username	A string indicating the user's logon name on the Linux server.
ServerId	An integer indicating the Keyfactor Command reference ID of the server on which the SSH logon resides.
ServerName	A string indicating the hostname of the SSH server on which the SSH logon resides. See SSH Servers on page 529 in the *Keyfactor Command Reference Guide* for more information.
GroupName	A string indicating the server group to which the server referenced by *ServerName* belongs. See SSH Server Groups on page 513 in the *Keyfactor Command Reference Guide* for more information.
ServerUnderManagement	A Boolean indicating whether the server on which the SSH logon resides is in *inventory only* mode (false) or *inventory and publish policy* mode (true).
KeyCount	An integer indicating the number of SSH keys associated with the Linux logons.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

POST SSH Logons

The POST /SSH/Logons method is used to create a new Linux logon in Keyfactor Command and, for servers in *inventory and publish policy* mode, publish it out to a Linux server. The logon can optionally be associated with one or more SSH keys by mapping the logon to one or more *users* or *service accounts* during creation. This method returns HTTP 200 OK on a success with details for the new SSH logon.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group to which the server on which the logon exists belongs and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 501: POST SSH Logons Input Parameters

Name	In	Description
Username	Body	**Required**. A string indicating the user's logon name on the Linux server.
ServerId	Body	**Required**. An integer indicating the Keyfactor Command reference ID of the server on which the SSH logon should be created. Use the *GET /SSH/Servers* method (see GET SSH Servers on page 1702) to retrieve a list of all the SSH servers to determine the server's ID.
UserIds	Body	An array of integers indicating the Keyfactor Command reference IDs for the users and/or service accounts with which the logon should be associated, provided in the following format: `[4,7,19]` See SSH on page 479 in the *Keyfactor Command Reference Guide* for more information about users and service accounts. Use the *GET /SSH/Users* method (see GET SSH Users on page 1800) to retrieve a list of all the users (including service accounts) created in Keyfactor Command to determine a user's ID.

Table 502: POST SSH Logons Response Data

Name	Description
ID	An integer indicating the Keyfactor Command reference ID for the SSH logon.
Username	A string indicating the user's logon name on the Linux server.
Server	Details about the server on which the SSH logon resides. Server information includes: **Name** / **Description** Id — An integer indicating the Keyfactor Command reference ID of the server on which the SSH logon resides. Hostname — A string indicating the hostname of the SSH server on which the SSH logon resides. See SSH Servers on page 529 in the *Keyfactor Command Reference Guide* for more information. UnderManagement — A Boolean indicating whether the server on which the SSH logon resides is in *inventory only* mode (false) or *inventory and publish policy* mode (true). GroupName — A string indicating the server group to which the server referenced by *Hostname* belongs. See SSH Server Groups on page 513 in the *Keyfactor Command Reference Guide* for more information.
KeyCount	An integer indicating the number of SSH keys associated with the Linux logons.
Access	An array of key/value pairs providing information about the users mapped to the logon. Access information includes: **Name** / **Description** Id — An integer indicating the Keyfactor Command reference ID of a *user* or *service account* that has been associated with the logon. See SSH on page 479 in the *Keyfactor Command Reference Guide* for more information. Username — A string indicating the username of a *user* (in DOMAIN\\username format) or *service account* (in username@hostname format) that has been associated with the logon.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

POST SSH Logons Access

The POST /SSH/Logons/Access method is used to associate one or more SSH keys with a Linux logon by mapping the logon to one or more *users* or *service accounts*. This method returns HTTP 200 OK on a success with a list of the users associated with the logon.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group to which the server on which the logon exists belongs and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 503: POST SSH Logons Access Input Parameters

Name	In	Description
LogonId	Body	**Required**. An integer indicating the Keyfactor Command reference ID for the SSH logon. Use the *GET /SSH/Logons* method (see GET SSH Logons on page 1689) to retrieve a list of all the SSH logons to determine the logon's ID.
UserIds	Body	An array of integers indicating the Keyfactor Command reference IDs for the users and/or service accounts with which the logon should be associated, provided in the following format: `[4,7,19]` Use the *GET /SSH/Users* method (see GET SSH Users on page 1800) to retrieve a list of all the users (including service accounts) created in Keyfactor Command to determine a user's ID. See SSH on page 479 in the *Keyfactor Command Reference Guide* for more information about users and service accounts.

Table 504: POST SSH Logons Access Response Data

Name	Description
LogonId	An integer indicating the Keyfactor Command reference ID for the SSH logon.
LogonName	A string indicating the user's logon name on the Linux server.
Users	An array of key/value pairs providing information about the users mapped to the logon. User information includes: **Name** / **Description** Id — An integer indicating the Keyfactor Command reference ID of a *user* or *service account* that has been associated with the logon. See SSH on page 479 in the *Keyfactor Command Reference Guide* for more information. Username — A string indicating the username of a *user* (in DOMAIN\\username format) or *service account* (in username@hostname format) that has been associated with the logon.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.25.3 SSH Servers

The SSH Servers component of the Keyfactor Web APIs includes methods necessary to create, update, and delete SSH servers within Keyfactor Command.

Table 505: SSH Servers Endpoints

Endpoint	Method	Description	Link
/{id}	DELETE	Deletes the SSH server with the specified ID.	DELETE SSH Servers ID on the next page
/{id}	GET	Returns the SSH server with the specified ID.	GET SSH Servers ID on the next page
/Access/{id}	GET	Retrieves Linux logons along with users and service accounts granted access to those logons for the specified SSH server.	GET SSH Servers Access ID on page 1700
/	GET	Returns a list of a SSH servers configured in Keyfactor Command.	GET SSH Servers on page 1702

Endpoint	Method	Description	Link
/	POST	Creates a new SSH server.	POST SSH Servers on page 1706
/	PUT	Updates an existing SSH server.	PUT SSH Servers on page 1711
/Access	DELETE	Deletes Linux logon to user and service account mappings for an SSH server.	DELETE SSH Servers Access on page 1716
/Access	POST	Creates Linux logon to user and service account mappings for an SSH server.	POST SSH Servers Access on page 1718

DELETE SSH Servers ID

The DELETE /SSH/Servers/{id} method is used to delete an SSH server in Keyfactor Command. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group to which the server belongs and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 506: DELETE SSH Servers {id} Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID for the SSH server to be deleted. Use the *GET /SSH/Servers* method (see GET SSH Servers on page 1702) to retrieve a list of all the SSH servers to determine the server's ID.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

GET SSH Servers ID

The GET /SSH/Servers/{id} method is used to retrieve an SSH server with the specified ID from Keyfactor Command. This method returns HTTP 200 OK on a success with details for the specified SSH server.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group to which the server belongs and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 507: GET SSH Servers {id} Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID for the SSH server to be retrieved. Use the *GET /SSH/Servers* method (see GET SSH Servers on page 1702) to retrieve a list of all the SSH servers to determine the server's ID.

Table 508: GET SSH Servers {id} Response Data

Name	Description
ID	An integer indicating the Keyfactor Command reference ID for the SSH server. This ID is automatically set by Keyfactor Command.
AgentId	A string indicating the Keyfactor Command reference GUID for the SSH orchestrator controlling the SSH server.
Hostname	A string indicating the hostname of the SSH server.
ServerGroupId	A string indicating the Keyfactor Command reference GUID for the SSH server group to which the server belongs.
SyncSchedule	An array providing the inventory schedule for the SSH server group to which the SSH server belongs. Inventory schedules cannot be set on an individual SSH server basis. The schedule can be off (unset) or one of the supported values. Supported schedule values are:

Name	Description
Off	Turn off a previously configured schedule.
Interval	A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.

Name	Description
Minutes	An integer indicating the number of minutes between each interval.

For example, every hour:

```
"Interval": {
   "Minutes": 60
}
```

Name	Description
Daily	A dictionary that indicates a job scheduled to run every day at the same time with the parameter:

Name	Description
Time	The date and time to next run the job. The date and time

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, daily at 11:30 pm:
<pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre>
</td></tr>
<tr><td>Weekly</td><td>A dictionary that indicates a job scheduled to run on a specific day or days every week at the same time with the parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
<tr><td>Days</td><td>An array of values representing the days of the week on which to run the job. These can either be entered as integers (0 for Sunday, 1 for Monday, etc.) or as days of the week (e.g. "Sunday").</td></tr>
</table>
For example, every Monday, Wednesday and Friday at 5:30 pm:
<pre>"Weekly": {
   "Days": [
      "Monday",
      "Wednesday",
      "Friday"
   ],
   "Time": "2022-02-27T17:30:00Z"
}</pre>
</td></tr>
<tr><td>Monthly</td><td>A dictionary that indicates a job scheduled to run on a specific day or days every month at the same time with the parameters:</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
<tr><td>Day</td><td>The number of the day, in the month, to run the job.</td></tr>
</table>
For example, on the first of every month at 5:30 pm:
<pre>"Monthly": {
   "Day": 1
   "Time": "2022-02-27T17:30:00Z"
}</pre>
Note: Although the Swagger Example Value may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint.
For example:
<pre>"SyncSchedule": {
   "Weekly": {
      "Days": [
         "Monday",
         "Wednesday",
         "Friday"
      ],
      "Time": "2022-11-20T14:00:00Z"
   }
}</pre>
</td></tr>
</table>
</td></tr>
<tr><td>Under-Management</td><td>A Boolean indicating whether the SSH server is in inventory only mode (False) or inventory and publish policy mode (True).
Tip: If the server group associated with the SSH server is in inventory and publish policy mode, you will not be able to configure the server in inventory only mode.</td></tr>
<tr><td>Owner</td><td>An array that indicates the Active Directory user who owns the server group to which the server belongs. The owner can only be set by a Keyfactor Command user with the SSH Enterprise Admin role. See SSH Server Groups on page 513 in the Keyfactor Command Reference Guide for more information. Owner parameters are:</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of the user who holds the owner role on the SSH server group to which the SSH server belongs.</td></tr>
<tr><td>Username</td><td>A string indicating the username of the user (in DOMAIN\\username format) who holds the owner role on the SSH server group to which the SSH server belongs.</td></tr>
</table>
</td></tr>
<tr><td>GroupName</td><td>A string indicating the SSH server group to which the SSH server belongs. See SSH Server Groups on page 513 in the Keyfactor Command Reference Guide for more information.</td></tr>
<tr><td>Orchestrator</td><td>A string indicating the name the SSH orchestrator provided to Keyfactor Command when it registered. This value is configurable when the orchestrator is installed.
For more information about the orchestrator, see Bash Orchestrator on page 2433 in the Keyfactor Orchestrators Installation and Configuration Guide.</td></tr>
<tr><td>Port</td><td>An integer indicating the port that is configured for SSH on the SSH server. The default is 22.</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

GET SSH Servers Access ID

The GET /SSH/Servers/Access/{id} method is used to retrieve Linux logons for an SSH server, along with any users or service accounts mapped to those logons, from Keyfactor Command for the specified server ID. This method returns HTTP 200 OK on a success with details of the logons and associated users, if applicable, for the specified SSH server.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group to which the server belongs and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 509: GET SSH Servers Access {id} Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID for the SSH server for which to retrieve logon and user mappings. Use the *GET /SSH/Servers* method (see GET SSH Servers on the next page) to retrieve a list of all the SSH servers to determine the server's ID.

Table 510: GET SSH Servers Access {id} Response Data

Name	Description
ServerId	An integer indicating the Keyfactor Command reference ID for the SSH server.
LogonUsers	An array containing information for the Linux logons from the Linux server that have been stored in Keyfactor Command. Possible information includes: **Name** / **Description** LogonId — An integer indicating the Keyfactor Command reference ID of the Linux logon. LogonName — A string indicating the name of the Linux logon. Users — An array of user objects containing information about the users and/or service accounts defined in Keyfactor Command that have been mapped to the Linux logon. User information includes: **Name** / **Description** Id — An integer indicating the Keyfactor Command reference ID of a *user* or *service account* that has been associated with the logon. See SSH on page 479 in the *Keyfactor Command Reference Guide* for more information. Username — A string indicating the username of a *user* (in DOMAIN\\username format) or *service account* (in username@hostname format) that has been associated with the logon.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

GET SSH Servers

The GET /SSH/Servers method is used to retrieve one or more SSH servers defined in Keyfactor Command. Results can be limited to selected servers using filtering, and URL parameters can be used to specify paging and the level of information detail. This method returns HTTP 200 OK on a success with details for the requested SSH servers.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group to which the server belongs and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 511: GET SSH Servers Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Using the SSH Server Search on page 535. The query fields supported for this endpoint are: • *Agent* (Agent ID) • *Hostname* • *Orchestrator* (ClientMachine) • *ServerGroup* (Server Group Id) • *ServerGroupName* • *ServerGroupOwner* (Username) • *EnforcePublishPolicy* (UnderManagement) (true, false)
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *Hostname*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 512: GET SSH Servers Response Data

Name	Description
ID	An integer indicating the Keyfactor Command reference ID for the SSH server. This ID is automatically set by Keyfactor Command.
AgentId	A string indicating the Keyfactor Command reference GUID for the SSH orchestrator controlling the SSH server.
Hostname	A string indicating the hostname of the SSH server.
ServerGroupId	A string indicating the Keyfactor Command reference GUID for the SSH server group to which the server belongs.
SyncSchedule	An array providing the inventory schedule for the SSH server group to which the SSH server belongs. Inventory schedules cannot be set on an individual SSH server basis. The schedule can be off (unset) or one of the supported values. Supported schedule values are:

Name	Description
Off	Turn off a previously configured schedule.
Interval	A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.

Name	Description
Minutes	An integer indicating the number of minutes between each interval.

For example, every hour:

```
"Interval": {
   "Minutes": 60
}
```

Name	Description
Daily	A dictionary that indicates a job scheduled to run every day at the same time with the parameter:

Name	Description

<tr><td>Owner</td><td>An array that indicates the Active Directory user who owns the server group to which the server belongs. The owner can only be set by a Keyfactor Command user with the SSH Enterprise Admin role. See SSH Server Groups on page 513 in the Keyfactor Command Reference Guide for more information. Owner parameters are:</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of the user who holds the owner role on the SSH server group to which the SSH server belongs.</td></tr>
<tr><td>Username</td><td>A string indicating the username of the user (in DOMAIN\\username format) who holds the owner role on the SSH server group to which the SSH server belongs.</td></tr>
</table>
</td></tr>
<tr><td>GroupName</td><td>A string indicating the SSH server group to which the SSH server belongs. See SSH Server Groups on page 513 in the Keyfactor Command Reference Guide for more information.</td></tr>
<tr><td>Orchestrator</td><td>A string indicating the name the SSH orchestrator provided to Keyfactor Command when it registered. This value is configurable when the orchestrator is installed.
For more information about the orchestrator, see Bash Orchestrator on page 2433 in the Keyfactor Orchestrators Installation and Configuration Guide.</td></tr>
<tr><td>Port</td><td>An integer indicating the port that is configured for SSH on the SSH server. The default is 22.</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

POST SSH Servers

The POST /SSH/Servers method is used to create a new SSH server in Keyfactor Command. This method returns HTTP 200 OK on a success with details for the new SSH server.

Before adding a new SSH server, be sure that you have added at least one server group (see POST SSH Server Groups on page 1736) and that your Keyfactor Bash Orchestrator has been registered and approved in Keyfactor Command (see GET Agents on page 727).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group to which the server belongs and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 513: POST SSH Servers Input Parameters

Name	In	Description
AgentId	Body	**Required**. A string indicating the Keyfactor Command reference GUID for the SSH orchestrator controlling the SSH server.
Hostname	Body	**Required**. A string indicating the hostname of the SSH server.
ServerGroupId	Body	**Required**. A string indicating the Keyfactor Command reference GUID for the SSH server group to which the server belongs.
UnderManagement	Body	A Boolean indicating whether the SSH server is in *inventory only* mode (False) or *inventory and publish policy* mode (True). **Tip:** If the server group associated with the SSH server is in *inventory and publish policy* mode, you will not be able to configure the server in *inventory only* mode.
Port	Body	An integer indicating the port that is configured for SSH on the SSH server. The default is 22.

Table 514: POST SSH Servers Response Data

Name	Description
ID	An integer indicating the Keyfactor Command reference ID for the SSH server. This ID is automatically set by Keyfactor Command.
AgentId	A string indicating the Keyfactor Command reference GUID for the SSH orchestrator controlling the SSH server.
Hostname	A string indicating the hostname of the SSH server.
ServerGroupId	A string indicating the Keyfactor Command reference GUID for the SSH server group to which the server belongs.
SyncSchedule	An array providing the inventory schedule for the SSH server group to which the SSH server belongs. Inventory schedules cannot be set on an individual SSH server basis. The schedule can be off (unset) or one of the supported values. Supported schedule values are:

Name	Description
Off	Turn off a previously configured schedule.
Interval	A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.

Name	Description
Minutes	An integer indicating the number of minutes between each interval.

For example, every hour:

```
"Interval": {
   "Minutes": 60
}
```

Name	Description

<tr><td>Port</td><td>An integer indicating the port that is configured for SSH on the SSH server. The default is 22.</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

PUT SSH Servers

The PUT /SSH/Servers method is used to update an existing SSH server in Keyfactor Command. This method returns HTTP 200 OK on a success with details for the SSH server.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group to which the server belongs and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Warning: Any previously populated fields that are not submitted with their full existing data using this method will be cleared of their existing data. When using this method, you should first do a GET to retrieve all the values for the record you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing.

Table 515: PUT SSH Servers Input Parameters

Name	In	Description
ID	Body	**Required**. The Keyfactor Command reference ID for the SSH server. This ID is automatically set by Keyfactor Command.
UnderManagement	Body	A Boolean indicating whether the SSH server is in *inventory only* mode (False) or *inventory and publish policy* mode (True). **Tip:** If the server group associated with the SSH server is in *inventory and publish policy* mode, you will not be able to configure the server in *inventory only* mode.
Port	Body	The port that is configured for SSH on the SSH server. The default is 22.

Table 516: PUT SSH Servers Response Data

Name	Description
ID	An integer indicating the Keyfactor Command reference ID for the SSH server. This ID is automatically set by Keyfactor Command.
AgentId	A string indicating the Keyfactor Command reference GUID for the SSH orchestrator controlling the SSH server.
Hostname	A string indicating the hostname of the SSH server.
ServerGroupId	A string indicating the Keyfactor Command reference GUID for the SSH server group to which the server belongs.
SyncSchedule	An array providing the inventory schedule for the SSH server group to which the SSH server belongs. Inventory schedules cannot be set on an individual SSH server basis. The schedule can be off (unset) or one of the supported values. Supported schedule values are:

Name	Description
Off	Turn off a previously configured schedule.
Interval	A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.

Name	Description
Minutes	An integer indicating the number of minutes between each interval.

For example, every hour:

```
"Interval": {
   "Minutes": 60
}
```

Name	Description
Daily	A dictionary that indicates a job scheduled to run every day at the same time with the parameter:

Name	Description
Time	The date and time to next run the job. The date and time

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>

   }
}</pre>
</td></tr>
</table>
</td></tr>
<tr><td>Under-Management</td><td>A Boolean indicating whether the SSH server is in inventory only mode (False) or inventory and publish policy mode (True).
Tip: If the server group associated with the SSH server is in inventory and publish policy mode, you will not be able to configure the server in inventory only mode.</td></tr>
<tr><td>Owner</td><td>An array that indicates the Active Directory user who owns the server group to which the server belongs. The owner can only be set by a Keyfactor Command user with the SSH Enterprise Admin role. See SSH Server Groups on page 513 in the Keyfactor Command Reference Guide for more information. Owner parameters are:</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of the user who holds the owner role on the SSH server group to which the SSH server belongs.</td></tr>
<tr><td>Username</td><td>A string indicating the username of the user (in DOMAIN\\username format) who holds the owner role on the SSH server group to which the SSH server belongs.</td></tr>
</table>
</td></tr>
<tr><td>GroupName</td><td>A string indicating the SSH server group to which the SSH server belongs. See SSH Server Groups on page 513 in the Keyfactor Command Reference Guide for more information.</td></tr>
<tr><td>Orchestrator</td><td>A string indicating the name the SSH orchestrator provided to Keyfactor Command when it registered. This value is configurable when the orchestrator is installed.
For more information about the orchestrator, see Bash Orchestrator on page 2433 in the Keyfactor Orchestrators Installation and Configuration Guide.</td></tr>
<tr><td>Port</td><td>An integer indicating the port that is configured for SSH on the SSH server. The default is 22.</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

DELETE SSH Servers Access

The DELETE /SSH/Servers/Access method is used to remove a mapping of Keyfactor Command users or service accounts to one or more Linux logons on one or more SSH servers. This method returns HTTP 200 OK on a success with details of the logons and remaining associated users, if applicable, for the specified SSH server(s).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group to which the server belongs and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Tip: Before deleting a logon to user mapping, be sure that you have switched the server from which you will removing your mapping (or its server group) to *inventory and publish policy* mode so that the key for the user will be removed from the server. If the server is in *inventory only* mode and you remove a

mapping for it in Keyfactor Command, the mapping will be removed in Keyfactor Command only and the key for the user will not be removed from the server.

Table 517: DELETE SSH Servers Access Input Parameters

Name	In	Description
ServerId	Body	**Required**. The Keyfactor Command reference ID for the SSH server.
LogonUsers	Body	**Required**. An array containing information for the Linux logon(s) to update. The following information should be included: **Name** / **Description** LogonName — A string indicating the name of the Linux logon. Users — An array of strings indicating the user names of one or more *users* (in DOMAIN\\username format) or *service accounts* (in user-name@hostname format) to be removed from association with the logon. For example: `"LogonUsers": [ { "LogonName": "johns", "Users": [ "KEYEXAMPLE\\jsmith" ] } ]`

Table 518: DELETE SSH Servers Access Response Data

Name	Description
ServerId	An integer indicating the Keyfactor Command reference ID for the SSH server.
LogonUsers	An array containing information for the Linux logons from the Linux server that have been stored in Keyfactor Command. Possible information includes: **Name** / **Description** LogonId — An integer indicating the Keyfactor Command reference ID of the Linux logon. LogonName — A string indicating the name of the Linux logon. Users — An array of user objects containing information about the users and/or service accounts defined in Keyfactor Command that have been mapped to the Linux logon. User information includes: **Name** / **Description** Id — An integer indicating the Keyfactor Command reference ID of a *user* or *service account* that has been associated with the logon. See SSH on page 479 in the *Keyfactor Command Reference Guide* for more information. Username — A string indicating the username of a *user* (in DOMAIN\\username format) or *service account* (in user-name@hostname format) that has been associated with the logon.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

POST SSH Servers Access

The POST /SSH/Servers/Access method is used to create a mapping of one or more Linux logons to Keyfactor Command users or service accounts for one or more SSH servers. This method returns HTTP 200 OK on a success with details of the logons and associated users, if applicable, for the specified SSH server(s).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group to which the server belongs and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Tip: Before creating a logon to user mapping, be sure that you have switched the server to which you will add your mapping (or its server group) to *inventory and publish policy* mode so that the key for the user will be published to the server. If the server is in *inventory only* mode and you add a mapping for it in Keyfactor Command, the mapping will appear in Keyfactor Command only and the key for the user will not be published out to the server.

Table 519: POST SSH Servers Access Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>ServerId</td><td>Body</td><td>Required. The Keyfactor Command reference ID for the SSH server.</td></tr>
<tr><td>LogonUsers</td><td>Body</td><td>Required. An array containing information for the Linux logon(s) to update. The following information should be included:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>LogonName</td><td>A string indicating the name of the Linux logon.</td></tr>
<tr><td>Users</td><td>An array of strings indicating the user names of one or more users (in DOMAIN\\username format) or service accounts (in user-name@hostname format) to be associated with the logon.</td></tr>
</table>
For example:
<pre>
"LogonUsers": [
   {
      "LogonName": "johns",
      "Users": [
         "KEYEXAMPLE\\jsmith"
      ]
   }
]
</pre></td></tr>
</table>

Table 520: POST SSH Servers Access Response Data

Name	Description
ServerId	An integer indicating the Keyfactor Command reference ID for the SSH server.
LogonUsers	An array containing information for the Linux logons from the Linux server that have been stored in Keyfactor Command. Possible information includes: **Name** / **Description** LogonId — An integer indicating the Keyfactor Command reference ID of the Linux logon. LogonName — A string indicating the name of the Linux logon. Users — An array of user objects containing information about the users and/or service accounts defined in Keyfactor Command that have been mapped to the Linux logon. User information includes: **Name** / **Description** Id — An integer indicating the Keyfactor Command reference ID of a *user* or *service account* that has been associated with the logon. See SSH on page 479 in the *Keyfactor Command Reference Guide* for more information. Username — A string indicating the username of a *user* (in DOMAIN\\username format) or *service account* (in username@hostname format) that has been associated with the logon.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.25.4 SSH Server Groups

The SSH Server Groups component of the Keyfactor Web APIs includes methods necessary to create, update and delete SSH server groups within Keyfactor Command.

Table 521: SSH Server Groups Endpoints

Endpoint	Method	Description	Link
/{id}	DELETE	Deletes the SSH server group with the specified ID.	DELETE SSH Server Groups ID on the

Endpoint	Method	Description	Link
			next page
/{id}	GET	Returns the SSH server group with the specified ID.	GET SSH Server Groups ID on the next page
/{name}	GET	Returns the SSH server group with the specified name.	GET SSH Server Groups Name on page 1726
/Access/{id}	GET	Retrieves Linux logons along with users and service accounts granted access to those logons for the specified SSH server group.	GET SSH Server Groups Access ID on page 1730
/	GET	Returns a list of a SSH server groups configured in Keyfactor Command.	GET SSH Server Groups on page 1731
/	POST	Creates a new SSH server group.	POST SSH Server Groups on page 1736
/	PUT	Updates an existing SSH server group.	PUT SSH Server Groups on page 1743
/Access	DELETE	Deletes Linux logon to user and service account mappings for an SSH server group.	DELETE SSH Server Groups Access on page 1750
/Access	POST	Creates Linux logon to user and service account mappings for an SSH server group.	POST SSH Server Groups Access on page 1751

DELETE SSH Server Groups ID

The DELETE /SSH/ServerGroups/{id} method is used to delete an SSH server group in Keyfactor Command. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *EnterpriseAdmin*

Table 522: DELETE SSH Server Groups {id} Input Parameters

Name	In	Description
id	Path	**Required**. A string indicating the Keyfactor Command reference GUID for the SSH server group to be deleted. Use the *GET /SSH/ServerGroups* method (see GET SSH Server Groups on page 1731) to retrieve a list of all the SSH server groups to determine the server group's GUID.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

GET SSH Server Groups ID

The GET /SSH/ServerGroups/{id} method is used to retrieve an SSH server group with the specified GUID from Keyfactor Command. This method returns HTTP 200 OK on a success with details for the specified SSH server group.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 523: GET SSH Server Groups {id} Input Parameters

Name	In	Description
id	Path	**Required**. A string indicating the Keyfactor Command reference GUID for the SSH server group to be retrieved. Use the *GET /SSH/ServerGroups* method (see GET SSH Server Groups on page 1731) to retrieve a list of all the SSH server groups to determine the server group's GUID.

Table 524: GET SSH Server Groups {id} Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>ID</td><td>A string indicating the Keyfactor Command reference GUID for the SSH server group. This GUID is automatically set by Keyfactor Command.</td></tr>
<tr><td>Owner</td><td>An object indicating the Active Directory user who owns the server group. See SSH Server Groups on page 513 in the Keyfactor Command Reference Guide for more information. Owner parameters are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of the user who holds the owner role on the SSH server group.</td></tr>
<tr><td>Username</td><td>A string indicating the username of the user (in DOMAIN\\username format) who holds the owner role on the SSH server group.</td></tr>
</table></td></tr>
<tr><td>GroupName</td><td>A string indicating the name of the SSH server group.</td></tr>
<tr><td>SyncSchedule</td><td>An array providing the inventory schedule for the SSH server group. The schedule can be off (unset) or one of the supported values. Supported schedule values are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
<tr><td>Interval</td><td>A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Minutes</td><td>An integer indicating the number of minutes between each interval.</td></tr>
</table>
For example, every hour:
<pre>"Interval": {
   "Minutes": 60
}</pre></td></tr>
<tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:</td></tr>
</table></td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, daily at 11:30 pm:
<pre>
"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}
</pre>
</td></tr>
<tr><td>Weekly</td><td>A dictionary that indicates a job scheduled to run on a specific day or days every week at the same time with the parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
<tr><td>Days</td><td>An array of values representing the days of the week on which to run the job. These can either be entered as integers (0 for Sunday, 1 for Monday, etc.) or as days of the week (e.g. "Sunday").</td></tr>
</table>
For example, every Monday, Wednesday and Friday at 5:30 pm:
<pre>
"Weekly": {
   "Days": [
      "Monday",
      "Wednesday",
      "Friday"
   ],
   "Time": "2022-02-27T17:30:00Z"
}
</pre>
</td></tr>
<tr><td>Monthly</td><td>A dictionary that indicates a job scheduled to run on a specific day or days every month at the same time with the parameters:</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
<tr><td>Day</td><td>The number of the day, in the month, to run the job.</td></tr>
</table>
For example, on the first of every month at 5:30 pm:
<pre>"Monthly": {
   "Day": 1
   "Time": "2022-02-27T17:30:00Z"
}</pre>
</td></tr>
</table>
Note: Although the Swagger Example Value may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint.
For example:
<pre>"SyncSchedule": {
   "Weekly": {
      "Days": [
         "Monday",
         "Wednesday",
         "Friday"
      ],
      "Time": "2022-11-20T14:00:00Z"
   }
}</pre>
</td></tr>
<tr><td>Under-Management</td><td>A Boolean indicating whether the SSH server group is in inventory only mode (False) or inventory and publish policy mode (True).</td></tr>
<tr><td>ServerCount</td><td>An integer indicating the number of SSH servers that belong to the server group.</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

GET SSH Server Groups Name

The GET /SSH/ServerGroups/{name} method is used to retrieve an SSH server group with the specified name from Keyfactor Command. This method returns HTTP 200 OK on a success with details for the specified SSH server group.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 525: GET SSH Server Groups {name} Input Parameters

Name	In	Description
name	Path	**Required**. A string indicating the full name of the SSH server group to be retrieved.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

GET SSH Server Groups Access ID

The GET /SSH/ServerGroups/Access/{id} method is used to retrieve Linux logons for an SSH server group, along with any users or service accounts mapped to those logons, from Keyfactor Command for the specified server group GUID. This method returns HTTP 200 OK on a success with details of the logons and associated users, if applicable, for the specified SSH server group.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 527: GET SSH Server Groups Access {id} Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference GUID for the SSH server group for which to retrieve logon and user mappings. Use the *GET /SSH/ServerGroups* method (see GET SSH Server Groups on the next page) to retrieve a list of all the SSH server groups to determine the server group's ID.

Table 528: GET SSH Server Groups Access {id} Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>ServerGroupId</td><td>The Keyfactor Command reference GUID for the SSH server group.</td></tr>
<tr><td>LogonUsers</td><td>An array containing information for the Linux logons from the Linux server that have been stored in Keyfactor Command. Possible information includes:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>LogonName</td><td>A string indicating the name of the Linux logon.

Tip: Logons only appear in the results if they exist with the same spelling on all servers in the server group.</td></tr>
<tr><td>Users</td><td>An array of user objects containing information about the users and/or service accounts defined in Keyfactor Command that are mapped to the Linux logon. User information includes:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of a user or service account that is associated with the logon. See SSH on page 479 in the Keyfactor Command Reference Guide for more information.</td></tr>
<tr><td>Username</td><td>A string indicating the username of a user (in DOMAIN\\username format) or service account (in username@hostname format) that is associated with the logon.</td></tr>
</table>
Tip: Users only appear in the results if they have been mapped to the same logon on all servers in the server group.</td></tr>
</table></td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

GET SSH Server Groups

The GET /SSH/ServerGroups method is used to retrieve one or more SSH server groups defined in Keyfactor Command. Results can be limited to selected server groups using filtering, and URL parameters can be used to

specify paging and the level of information detail. This method returns HTTP 200 OK on a success with details for the requested SSH server groups.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 529: GET SSH Server Groups Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Using the Server Group Search on page 528. The query fields supported for this endpoint are: • *GroupId* • *GroupName* • *Owner* (Owner ID) • *OwnerName* (Username) • *EnforcePublishPolicy* (Under Management) (true, false)
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *GroupName*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 530: GET SSH Server Groups Response Data

Name	Description
ID	A string indicating the Keyfactor Command reference GUID for the SSH server group. This GUID is automatically set by Keyfactor Command.
Owner	An object indicating the Active Directory user who owns the server group. See SSH Server Groups on page 513 in the *Keyfactor Command Reference Guide* for more information. Owner parameters are: **Name** / **Description** Id — An integer indicating the Keyfactor Command reference ID of the *user* who holds the owner role on the SSH server group. Username — A string indicating the username of the *user* (in DOMAIN\\username format) who holds the owner role on the SSH server group.
GroupName	A string indicating the name of the SSH server group.
SyncSchedule	An array providing the inventory schedule for the SSH server group. The schedule can be off (unset) or one of the supported values. Supported schedule values are: **Name** / **Description** Off — Turn off a previously configured schedule. Interval — A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database. **Name** / **Description** Minutes — An integer indicating the number of minutes between each interval. For example, every hour: `"Interval": { "Minutes": 60 }` Daily — A dictionary that indicates a job scheduled to run every day at the same time with the parameter:

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, daily at 11:30 pm:
<pre>
"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}
</pre>
</td></tr>
<tr><td>Weekly</td><td>A dictionary that indicates a job scheduled to run on a specific day or days every week at the same time with the parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
<tr><td>Days</td><td>An array of values representing the days of the week on which to run the job. These can either be entered as integers (0 for Sunday, 1 for Monday, etc.) or as days of the week (e.g. "Sunday").</td></tr>
</table>
For example, every Monday, Wednesday and Friday at 5:30 pm:
<pre>
"Weekly": {
   "Days": [
      "Monday",
      "Wednesday",
      "Friday"
   ],

</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

POST SSH Server Groups

The POST /SSH/ServerGroups method is used to create an SSH server groups defined in Keyfactor Command. This method returns HTTP 200 OK on a success with details for the new SSH server group.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *EnterpriseAdmin*

Table 531: POST SSH Server Groups Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>OwnerName</td><td>Body</td><td>Required. A string indicating the Active Directory user who owns the server group (in DOMAIN\\username format). The owner can only be set by a Keyfactor Command user with the SSH Enterprise Admin role. See <a>SSH Server Groups on page 513 in the Keyfactor Command Reference Guide for more information.

Tip: Notice that the field name and structure returned on a GET is not the same as that used on a POST and PUT for the server group owner.</td></tr>
<tr><td>GroupName</td><td>Body</td><td>Required. A string indicating the name of the SSH server group.</td></tr>
<tr><td>SyncSchedule</td><td>Body</td><td>An array providing the inventory schedule for the SSH server group. The schedule can be off (unset) or one of the supported values. Supported schedule values are:

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Off</td><td>Turn off a previously configured schedule.</td></tr>
<tr><td>Interval</td><td>A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Minutes</td><td>An integer indicating the number of minutes between each interval.</td></tr>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

PUT SSH Server Groups

The PUT /SSH/ServerGroups method is used to update an existing SSH server groups defined in Keyfactor Command. This method returns HTTP 200 OK on a success with details for the updated SSH server group.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Warning: Any previously populated fields that are not submitted with their full existing data using this method will be cleared of their existing data. When using this method, you should first do a GET to retrieve all the values for the record you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing.

Table 533: PUT SSH Server Groups Input Parameters

Name	In	Description
ID	Body	A string indicating the Keyfactor Command reference GUID for the SSH server group. This GUID is automatically set by Keyfactor Command.
OwnerName	Body	**Required**. A string indicating the Active Directory user who owns the server group (in DOMAIN\\username format). The owner can only be set by a Keyfactor Command user with the *SSH Enterprise Admin* role. See SSH Server Groups on page 513 in the *Keyfactor Command Reference Guide* for more information. **Tip:** Notice that the field name and structure returned on a GET is not the same as that used on a POST and PUT for the server group owner.
GroupName	Body	**Required**. A string indicating the name of the SSH server group.
SyncSchedule	Body	An array providing the inventory schedule for the SSH server group. The schedule can be off (unset) or one of the supported values. Supported schedule values are: **Off** — Turn off a previously configured schedule. **Interval** — A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database. **Minutes** — An integer indicating the number of minutes between each interval. For example, every hour: `"Interval": { "Minutes": 60 }` **Daily** — A dictionary that indicates a job scheduled to run every day at the same time with the parameter:

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, daily at 11:30 pm:
<pre>

</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

DELETE SSH Server Groups Access

The DELETE /SSH/ServerGroups/Access method is used to remove a mapping of one or more Linux logons to Keyfactor Command users or service accounts for one or more SSH server groups. This method returns HTTP 200 OK on a success with details of the logons and associated users, if applicable, for the specified SSH server group(s).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Tip: Before deleting a logon to user mapping, be sure that you have switched the server group from which you will removing your mapping to *inventory and publish policy* mode so that the key for the user will be removed from the servers in the server group. If the server group is in *inventory only* mode and you remove a mapping for it in Keyfactor Command, the mapping will be removed in Keyfactor Command only and the key for the user will not be removed from the servers.

Table 535: DELETE SSH Server Groups Access Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>ServerGroupId</td><td>Body</td><td>Required. The Keyfactor Command reference ID for the SSH server group.</td></tr>
<tr><td>LogonUsers</td><td>Body</td><td>An array containing information for the Linux logon(s) to update. The following information should be included:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>LogonName</td><td>A string indicating the name of the Linux logon.</td></tr>
<tr><td>Users</td><td>An array of strings indicating the user names of one or more users (in DOMAIN\\username format) or service accounts (in username@hostname format) to be removed from association with the logon.</td></tr>
</table>
For example:
<pre>
"LogonUsers": [
   {
      "LogonName": "johns",
      "Users": [
         "KEYEXAMPLE\\jsmith"
      ]
   }
]
</pre></td></tr>
</table>

Table 536: DELETE SSH Server Groups Access {id} Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>ServerGroupId</td><td>The Keyfactor Command reference GUID for the SSH server group.</td></tr>
<tr><td>LogonUsers</td><td>An array containing information for the Linux logons from the Linux server that have been stored in Keyfactor Command. Possible information includes:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>LogonName</td><td>A string indicating the name of the Linux logon.
Tip: Logons only appear in the results if they exist with the same spelling on all servers in the server group.</td></tr>
<tr><td>Users</td><td>An array of user objects containing information about the users and/or service accounts defined in Keyfactor Command that are mapped to the Linux logon. User information includes:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of a user or service account that is associated with the logon. See SSH on page 479 in the Keyfactor Command Reference Guide for more information.</td></tr>
<tr><td>Username</td><td>A string indicating the username of a user (in DOMAIN\\username format) or service account (in username@hostname format) that is associated with the logon.</td></tr>
</table>
Tip: Users only appear in the results if they have been mapped to the same logon on all servers in the server group.</td></tr>
</table></td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

POST SSH Server Groups Access

The POST /SSH/ServerGroups/Access method is used to create a mapping of one or more Linux logons to Keyfactor Command users or service accounts for one or more SSH server groups. This method returns HTTP 200 OK on a success with details of the logons and associated users, if applicable, for the specified SSH server group(s).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Tip: Before creating a logon to user mapping, be sure that you have switched the server group to which you will add your mapping to *inventory and publish policy* mode so that the key for the user will be published to the servers in the group. If the server group is in *inventory only* mode and you add a mapping for it in Keyfactor Command, the mapping will appear in Keyfactor Command only and the key for the user will not be published out to the servers.

Table 537: POST SSH Server Groups Access Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>ServerGroupId</td><td>Body</td><td>Required. The Keyfactor Command reference ID for the SSH server group.</td></tr>
<tr><td>LogonUsers</td><td>Body</td><td>Required. An array containing information for the Linux logon(s) to update. The following information should be included:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>LogonName</td><td>A string indicating the name of the Linux logon.</td></tr>
<tr><td>Users</td><td>An array of strings indicating the user names of one or more users (in DOMAIN\\username format) or service accounts (in username@hostname format) to be associated with the logon.</td></tr>
</table>
For example:
<pre>
"LogonUsers": [
   {
      "LogonName": "johns",
      "Users": [

</table>

Table 538: POST SSH Server Groups Access {id} Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>ServerGroupId</td><td>The Keyfactor Command reference GUID for the SSH server group.</td></tr>
<tr><td>LogonUsers</td><td>An array containing information for the Linux logons from the Linux server that have been stored in Keyfactor Command. Possible information includes:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>LogonName</td><td>A string indicating the name of the Linux logon.

Tip: Logons only appear in the results if they exist with the same spelling on all servers in the server group.</td></tr>
<tr><td>Users</td><td>An array of user objects containing information about the users and/or service accounts defined in Keyfactor Command that are mapped to the Linux logon. User information includes:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of a user or service account that is associated with the logon. See SSH on page 479 in the Keyfactor Command Reference Guide for more information.</td></tr>
<tr><td>Username</td><td>A string indicating the username of a user (in DOMAIN\\username format) or service account (in username@hostname format) that is associated with the logon.</td></tr>
</table>
Tip: Users only appear in the results if they have been mapped to the same logon on all servers in the server group.</td></tr>
</table></td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.25.5 SSH Service Accounts

The SSH Service Accounts component of the Keyfactor Web APIs includes methods necessary to retrieve, create, update, rotate and delete service accounts and associated keys in Keyfactor Command.

Table 539: SSH Service Accounts Endpoints

Endpoint	Method	Description	Link
/{id}	DELETE	Deletes the SSH service account with the specified ID.	DELETE SSH Service Accounts ID below
/{id}	GET	Returns the SSH service account with the specified ID.	GET SSH Service Accounts ID on page 1756
/Key/{id}	GET	Returns the public key and optional private key of an SSH service account with the specified ID.	GET SSH Service Accounts Key ID on page 1762
/	DELETE	Deletes one or more SSH service accounts with the specified IDs.	DELETE SSH Service Accounts on page 1766
/	GET	Returns a list of SSH service accounts based on the specified filters.	GET SSH Service Accounts on page 1768
/	POST	Creates a new SSH service account.	POST SSH Service Accounts on page 1775
/	PUT	Updates an existing SSH service account.	PUT SSH Service Accounts on page 1784
/Rotate/{id}	POST	Generates a new key pair for an existing service account.	POST SSH Service Accounts Rotate ID on page 1791

DELETE SSH Service Accounts ID

The DELETE /SSH/ServiceAccounts/{id} method is used to delete an SSH service account in Keyfactor Command, including its SSH key pair. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group with which the key is associated and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 540: DELETE SSH Service Accounts {id} Input Parameters

Name	In	Description

id	Path	**Required**. An integer indicating the Keyfactor Command reference ID for the SSH service account to be deleted.
		Use the *GET /SSH/ServiceAccounts* method (see GET SSH Service Accounts on page 1768) to retrieve a list of all the SSH service accounts to determine the service account's ID.
		
		Tip: Be sure to use the ID of the service account itself and not the ID of the service account user or service account's key within the service account. For example, notice the following record returned from a GET /SSH/ServiceAccounts:
		<pre>{
		"Id": 2,
		"ClientHostname": "appsrvr80.keyexample.com",
		"ServerGroup": {
		"Id": "603d3d4c-89dd-4ab8-92e1-8e83db3d5546",
		"GroupName": "Server Group Two",
		"UnderManagement": false
		},
		"User": {
		"Id": 7,
		"Key": {
		"Id": 36,
		"Fingerprint":
		"kwuo2k3Ej7wFVMLhI3g+rxt2qXwGp7qcvzdBjVTDHNg=",
		"PublicKey": "ssh-rsa
		AAAAB3NzaC1yc2EAAAADAQABAAABAQCAln+t [truncated for
		display]",
		"KeyType": "RSA",
		"KeyLength": 2048,
		"CreationDate": "2020-11-17T17:53:55.68",
		"Email": "pkiadmins@keyexample.com",
		"Comments": [
		"Access App Two"
		],
		"LogonCount": 3
		},
		"Username": "svc_access2@appsrvr80.keyexample.com"
		}
		}</pre>It contains three IDs:
		• ID 2: The service account's ID. Use this one for delete requests.
		• ID 7: The service account user's ID.
		• ID 36: The ID of the service account user's key.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

GET SSH Service Accounts ID

The GET /SSH/ServiceAccounts/{id} method is used to retrieve an SSH service account from Keyfactor Command. This method returns HTTP 200 OK on a success with details for the requested SSH service account and its public key. To return the SSH private key, use the GET /SSH/ServiceAccounts/Key/{id} method (see GET SSH Service Accounts Key ID on page 1762).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group with which the key is associated and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 541: GET SSH Service Accounts {id} Input Parameters

Name	In	Description
id	Path	**Required**. An integer indicating the Keyfactor Command reference ID for the SSH service account to be retrieved. Use the *GET /SSH/ServiceAccounts* method (see GET SSH Service Accounts on page 1768) to retrieve a list of all the SSH service accounts to determine the service account's ID.

Table 542: GET SSH Service Accounts {id} Response Data

Name	Description
ID	The Keyfactor Command reference ID for the SSH service account. This ID is automatically set by Keyfactor Command.
ClientHostname	A string indicating the client hostname reference for the service account key. This field is used for reference only and does not need to match an actual client hostname. It is used when building the full user name of the service account key for mapping to Linux logons for publishing to Linux servers (e.g. username@client_hostname). The naming convention is to enter the hostname of the server on which the application that will use the private key resides (e.g. appsrvr12), but you can put anything you like in this field (e.g. cheesetoast).
ServerGroup	An array that indicates the SSH server group for the service account. The server group is used to control who has access in Keyfactor Command to the service account key. It does not limit where the key can be published. See SSH Permissions on page 549 in the *Keyfactor Command Reference Guide* for more information. Server group information includes:

Name	Description
Id	A string indicating the Keyfactor Command reference GUID of the SSH server group.
Owner	An object indicating the Active Directory user who owns the server group. See SSH Server Groups on page 513 in the *Keyfactor Command Reference Guide* for more information.

Name	Description
Id	An integer indicating the Keyfactor Command reference ID of the *user* who holds the owner role on the SSH server group.

GroupName	A string indicating the name of the SSH server group.
SyncSchedule	An array providing the inventory schedule for the SSH server group. The schedule can be off (unset) or one of the supported values. Supported schedule values are:

Name	Description
Off	Turn off a previously configured schedule.

Name	Description
	Name / **Description**

Name / **Description**

Name	Description
Interval	A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database. **Name** / **Description** Minutes — An integer indicating the number of minutes between each interval. For example, every hour: `"Interval": { "Minutes": 60 }`
Daily	A dictionary that indicates a job scheduled to run every day at the same time with the parameter: **Name** / **Description** Time — The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z). For example, daily at 11:30 pm: `"Daily": { "Time": "2022-02-25T23:30:00Z" }`
Weekly	A dictionary that indicates a job scheduled to run on a specific day or days every week at the same time with the parameters:

Name	Description
	Name / **Description** Time — The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z). Days — An array of values representing the days of the week on which to run the job. These can either be entered as integers (0 for Sunday, 1 for Monday, etc.) or as days of the week (e.g. "Sunday"). For example, every Monday, Wednesday and Friday at 5:30 pm: `"Weekly": { "Days": [ "Monday", "Wednesday", "Friday" ], "Time": "2022-02-27T17:30:00Z" }` Monthly — A dictionary that indicates a job scheduled to run on a specific day or days every month at the same time with the parameters: Time — The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z). Day — The number of the day, in the month, to run the job. For example, on the first of every month at 5:30 pm:

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td><pre>"Monthly": {
   "Day": 1
   "Time": "2022-02-27T17:30:00Z"
}</pre></td></tr>
</table>
Note: Although the Swagger Example Value may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint.
</td></tr>
<tr><td>Under-Management</td><td>A Boolean indicating whether the SSH server group is in inventory only mode (False) or inventory and publish policy mode (True).</td></tr>
</table>
</td></tr>
<tr><td>User</td><td>An array containing information about the service account user. Service account user details include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of the SSH service account user.</td></tr>
<tr><td>Key</td><td>An array containing information about the key for the service account user. Key details include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of the SSH service account's key.</td></tr>
<tr><td>Fingerprint</td><td>A string indicating the fingerprint of the public key. Each SSH public key has a single cryptographic fingerprint that can be used to uniquely identify the key.</td></tr>
<tr><td>PublicKey</td><td>A string indicating the public key of the key pair for the SSH service account.</td></tr>
<tr><td>KeyType</td><td>A string indicating the cryptographic algorithm used to</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>generate the SSH key. Possible values are:
RSA
ECDSA
Ed25519</td></tr>
<tr><td>KeyLength</td><td>An integer indicating the key length for the SSH key. The key length supported depends on the key type selected. Keyfactor Command supports 256 bits for Ed25519 and ECDSA and 2048 or 4096 bits for RSA.</td></tr>
<tr><td>CreationDate</td><td>The date, in UTC, on which the SSH key pair was created.</td></tr>
<tr><td>StaleDate</td><td>The date, in UTC, after which the SSH key pair is considered to be out of date based on the key lifetime defined by the Key Lifetime (days) application setting. See Application Settings: SSH Tab on page 572 in the Keyfactor Command Reference Guide for more information.</td></tr>
<tr><td>Email</td><td>A string containing the email address of the administrator or group of administrators responsible for managing the key. This email address is used to alert the administrator or group of administrators when the key pair is approaching the end of its lifetime.</td></tr>
<tr><td>Comments</td><td>An array containing one or more strings with the user-defined descriptive comments, if any, on the key. Although entry of an email address in the comment field of an SSH key is traditional, this is not a required format. The comment may can contain any characters supported for string fields, including spaces and most punctuation marks. Keys created through the Keyfactor Command Management Portal or with the POST /SSH/ServiceAccounts method will contain only one string in the array.</td></tr>
<tr><td>LogonCount</td><td>An integer indicating the number of Linux logons associated with the SSH key pair.</td></tr>
</table>
</td></tr>
</table>
</td></tr>
<tr><td>Username</td><td>A string indicating the full username of the service account. The username is made up of the user name and ClientHostname entered when the service account is created (e.g. myapp@appsrvr75).</td></tr>
</table>

Name	Description
LogonIds	An array of integers indicating the Keyfactor Command reference IDs of Linux logons that are associated with the service account in order to publish the service account's public key to the servers on which the logons are located.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

GET SSH Service Accounts Key ID

The GET /SSH/ServiceAccounts/Key/{id} method is used to retrieve the key information for an SSH service account from Keyfactor Command. This method returns HTTP 200 OK on a success with details for the requested SSH service account key, including optional private key.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group with which the key is associated and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 543: GET SSH Service Accounts Key {id} Input Parameters

Name	In	Description

id	Path	**Required**. The Keyfactor Command reference ID for the SSH service account key for which to retrieve key information.
		Use the *GET /SSH/ServiceAccounts* method (see GET SSH Service Accounts on page 1768) to retrieve a list of all the SSH service accounts to determine the service account's key ID.
		
		  **Tip:** Be sure to use the ID of the service account's key and not the ID of the service account itself or the service account user. For example, notice the following record returned from a GET /SSH/ServiceAccounts:
		<pre>{
		"Id": 2,
		"ClientHostname": "appsrvr80.keyexample.com",
		"ServerGroup": {
		"Id": "603d3d4c-89dd-4ab8-92e1-8e83db3d5546",
		"GroupName": "Server Group Two",
		"UnderManagement": false
		},
		"User": {
		"Id": 7,
		"Key": {
		"Id": 36,
		"Fingerprint":
		"kwuo2k3Ej7wFVMLhI3g+rxt2qXwGp7qcvzdBjVTDHNg=",
		"PublicKey": "ssh-rsa
		AAAAB3NzaC1yc2EAAAADAQABAAABAQCAln+t [truncated for
		display]",
		"KeyType": "RSA",
		"KeyLength": 2048,
		"CreationDate": "2020-11-17T17:53:55.68",
		"Email": "pkiadmins@keyexample.com",
		"Comments": [
		"Access App Two"
		],
		"LogonCount": 3
		},
		"Username": "svc_
		access2@appsrvr80.keyexample.com"
		}
		}</pre>It contains three IDs:
		• ID 2: The service account's ID.
		• ID 7: The service account user's ID.

Name	In	Description
		 • ID 36: The ID of the service account user's key. Use this one to request the key.
IncludePrivateKey	Query	A Boolean that sets whether to include the private key of the SSH key pair in the response (True) or not (False). The default is *False*. If set to True, the X-Keyfactor-Key-Passphrase header must be supplied.

Table 544: GET SSH Service Accounts Key {id} Response Data

Name	Description
ID	The Keyfactor Command reference ID for the SSH service account. This ID is automatically set by Keyfactor Command.
Fingerprint	A string indicating the fingerprint of the public key. Each SSH public key has a single cryptographic fingerprint that can be used to uniquely identify the key.
PublicKey	A string indicating the public key of the key pair for the SSH service account.
PrivateKey	A string indicating the private key of the key pair for the SSH service account.
KeyType	A string indicating the cryptographic algorithm used to generate the SSH key. Possible values are: • RSA • ECDSA • Ed25519
KeyLength	An integer indicating the key length for the SSH key. The key length supported depends on the key type selected. Keyfactor Command supports 256 bits for Ed25519 and ECDSA and 2048 or 4096 bits for RSA.
CreationDate	The date, in UTC, on which the SSH key pair was created.
StaleDate	The date, in UTC, after which the SSH key pair is considered to be out of date based on the key life-time defined by the *Key Lifetime (days)* application setting. See Application Settings: SSH Tab on page 572 in the *Keyfactor Command Reference Guide* for more information.
Email	A string containing the email address of the administrator or group of administrators responsible for managing the key. This email address is used to alert the administrator or group of administrators when the key pair is approaching the end of its lifetime.
Comments	An array containing one or more strings with the user-defined descriptive comments, if any, on the key. Although entry of an email address in the comment field of an SSH key is traditional, this is not a required format. The comment may can contain any characters supported for string fields, including spaces and most punctuation marks. Keys created through the Keyfactor Command Management Portal or with the POST /SSH/ServiceAccounts method will contain only one string in the array.
LogonCount	An integer indicating the number of Linux logons associated with the SSH key pair.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

DELETE SSH Service Accounts

The DELETE /SSH/ServiceAccounts method is used to delete one or more SSH service accounts in Keyfactor Command, including their SSH key pairs. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group with which the key is associated and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 545: DELETE SSH Service Accounts Input Parameters

Name	In	Description

ids	Body	**Required**. An array of Keyfactor Command reference IDs for the SSH service accounts to be deleted provided in the request body in the following format:
		`[4,12,17]`
		Use the *GET /SSH/ServiceAccounts* method (see GET SSH Service Accounts on the next page) to retrieve a list of all the SSH service accounts to determine the service accounts IDs.
		
		Tip: Be sure to use the ID of the service account itself and not the ID of the service account user or service account's key within the service account. For example, notice the following record returned from a GET /SSH/ServiceAccounts:
		<pre>{
		  "Id": 2,
		  "ClientHostname": "appsrvr80.keyexample.com",
		  "ServerGroup": {
		  "Id": "603d3d4c-89dd-4ab8-92e1-8e83db3d5546",
		  "GroupName": "Server Group Two",
		  "UnderManagement": false
		  },
		  "User": {
		  "Id": 7,
		  "Key": {
		  "Id": 36,
		  "Fingerprint": "kwuo2k3Ej7wFVMLhI3g+rxt2qXwGp7qcvzdBjVTDHNg=",
		  "PublicKey": "ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAABAQCAln+t [truncated for display]",
		  "KeyType": "RSA",
		  "KeyLength": 2048,
		  "CreationDate": "2020-11-17T17:53:55.68",
		  "Email": "pkiadmins@keyexample.com",
		  "Comments": [
		  "Access App Two"
		  ],
		  "LogonCount": 3
		  },
		  "Username": "svc_access2@appsrvr80.keyexample.com"
		  }
		}</pre>It contains three IDs:
		• ID 2: The service account's ID. Use this one for delete requests.
		• ID 7: The service account user's ID.
		• ID 36: The ID of the service account user's key.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

GET SSH Service Accounts

The GET /SSH/ServiceAccounts method is used to retrieve one or more SSH service accounts defined in Keyfactor Command. Results can be limited to selected service accounts using filtering, and URL parameters can be used to specify paging and the level of information detail. This method returns HTTP 200 OK on a success with details for the requested SSH service accounts and their public keys. To return the SSH private key, use the GET /SSH/ServiceAccounts/Key/{id} method (see GET SSH Service Accounts Key ID on page 1762).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group with which the key is associated and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 546: GET SSH Service Accounts Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Using the Service Account Key Search on page 506. The query fields supported for this endpoint are: • *CreationDate* • *Id* • *Comments* (Key comments) • *KeyLength* • *KeyType* • *ServerGroup* (Server Group ID) • *ServerGroupName* • *Username*
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *Username*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 547: GET SSH Service Accounts Response Data

Name	Description
ID	The Keyfactor Command reference ID for the SSH service account. This ID is automatically set by Keyfactor Command.
ClientHostname	A string indicating the client hostname reference for the service account key. This field is used for reference only and does not need to match an actual client hostname. It is used when building the full user name of the service account key for mapping to Linux logons for publishing to Linux servers (e.g. username@client_hostname). The naming convention is to enter the hostname of the server on which the application that will use the private key resides (e.g. appsrvr12), but you can put anything you like in this field (e.g. cheesetoast).
ServerGroup	An array that indicates the SSH server group for the service account. The server group is used to control who has access in Keyfactor Command to the service account key. It does not limit where the key can be published. See SSH Permissions on page 549 in the *Keyfactor Command Reference Guide* for more information. Server group information includes:

Name	Description
Id	A string indicating the Keyfactor Command reference GUID of the SSH server group.
Owner	An object indicating the Active Directory user who owns the server group. See SSH Server Groups on page 513 in the *Keyfactor Command Reference Guide* for more information.

Name	Description
Id	An integer indicating the Keyfactor Command reference ID of the *user* who holds the owner role on the SSH server group.

GroupName	A string indicating the name of the SSH server group.
SyncSchedule	An array providing the inventory schedule for the SSH server group. The schedule can be off (unset) or one of the supported values. Supported schedule values are:

Name	Description
Off	Turn off a previously configured schedule.

Name	Description
	Name / **Description**

Name / **Description**

Name	Description
Interval	A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database. **Name** / **Description** Minutes — An integer indicating the number of minutes between each interval. For example, every hour: `"Interval": { "Minutes": 60 }`
Daily	A dictionary that indicates a job scheduled to run every day at the same time with the parameter: **Name** / **Description** Time — The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z). For example, daily at 11:30 pm: `"Daily": { "Time": "2022-02-25T23:30:00Z" }`
Weekly	A dictionary that indicates a job scheduled to run on a specific day or days every week at the same time with the parameters:

Name	Description
	Name / **Description** Time — The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z). Days — An array of values representing the days of the week on which to run the job. These can either be entered as integers (0 for Sunday, 1 for Monday, etc.) or as days of the week (e.g. "Sunday"). For example, every Monday, Wednesday and Friday at 5:30 pm: `"Weekly": { "Days": [ "Monday", "Wednesday", "Friday" ], "Time": "2022-02-27T17:30:00Z" }` Monthly — A dictionary that indicates a job scheduled to run on a specific day or days every month at the same time with the parameters: Time — The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z). Day — The number of the day, in the month, to run the job. For example, on the first of every month at 5:30 pm:

<table>

ECDSA
Ed25519</td></tr>
<tr><td>KeyLength</td><td>An integer indicating the key length for the SSH key. The key length supported depends on the key type selected. Keyfactor Command supports 256 bits for Ed25519 and ECDSA and 2048 or 4096 bits for RSA.</td></tr>
<tr><td>CreationDate</td><td>The date, in UTC, on which the SSH key pair was created.</td></tr>
<tr><td>StaleDate</td><td>The date, in UTC, after which the SSH key pair is considered to be out of date based on the key lifetime defined by the Key Lifetime (days) application setting. See Application Settings: SSH Tab on page 572 in the Keyfactor Command Reference Guide for more information.</td></tr>
<tr><td>Email</td><td>A string containing the email address of the administrator or group of administrators responsible for managing the key. This email address is used to alert the administrator or group of administrators when the key pair is approaching the end of its lifetime.</td></tr>
<tr><td>Comments</td><td>An array containing one or more strings with the user-defined descriptive comments, if any, on the key. Although entry of an email address in the comment field of an SSH key is traditional, this is not a required format. The comment may can contain any characters supported for string fields, including spaces and most punctuation marks. Keys created through the Keyfactor Command Management Portal or with the POST /SSH/ServiceAccounts method will contain only one string in the array.</td></tr>
<tr><td>LogonCount</td><td>An integer indicating the number of Linux logons associated with the SSH key pair.</td></tr>
</table>
</td></tr>
</table>
</td></tr>
<tr><td>Username</td><td>A string indicating the full username of the service account. The username is made up of the user name and ClientHostname entered when the service account is created (e.g. myapp@appsrvr75).</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

POST SSH Service Accounts

The POST /SSH/ServiceAccounts method is used to create a new SSH service account in Keyfactor Command. This method returns HTTP 200 OK on a success with details for the new SSH service account.

Before adding a new SSH service account, be sure that you have added at least one server group (see POST SSH Server Groups on page 1736) and that your Keyfactor Bash Orchestrator has been registered and approved in Keyfactor Command (see GET Agents on page 727).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group with which the key is associated and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 548: POST SSH Service Accounts Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>KeyGenerationRequest</td><td>Body</td><td>Required. An array that set the information to include in the SSH key pair request. Key generation request details include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>KeyType</td><td>Required. A string indicating the cryptographic algorithm used to generate the SSH key. Possible values are:
<table>
<tr><th>Numeric Value</th><th>Text Value</th></tr>
<tr><td>1</td><td>ECDSA</td></tr>
<tr><td>2</td><td>Ed25519</td></tr>
<tr><td>3</td><td>RSA</td></tr>
</table>
The KeyType may be specified using either the numeric value or text value.</td></tr>
<tr><td>PrivateKeyFormat</td><td>Required. A string indicating the format to use for the downloadable private key. Possible values are:
<table>
<tr><th>Numeric Value</th><th>Text Value</th></tr>
<tr><td>1</td><td>OpenSSH</td></tr>
<tr><td>2</td><td>PKCS8</td></tr>
</table>
The PrivateKeyFormat may be specified using either the numeric value or text value.</td></tr>
<tr><td>KeyLength</td><td>Required*. An integer indicating the key length for the SSH key. The key length supported depends on the key type selected. Keyfactor Command supports 256 bits for Ed25519 and ECDSA and 2048 or 4096 bits for RSA. This field is optional if the KeyType is set to ECDSA or Ed25519 and required if the KeyType is set to RSA.</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Email</td><td>Required. A string containing the email address of the administrator or group of administrators responsible for managing the key. This email address is used to alert the administrator or group of administrators when the key pair is approaching the end of its lifetime.</td></tr>
<tr><td>Password</td><td>Required. A string that sets a password used to secure the private key of the SSH key pair for download.</td></tr>
<tr><td>Comment</td><td>A string containing the user-defined descriptive comment, if any, on the key. Although entry of an email address in the comment field of an SSH key is traditional, this is not a required format. The comment may can contain any characters supported for string fields, including spaces and most punctuation marks.</td></tr>
</table>
</td></tr>
<tr><td>User</td><td>Body</td><td>Required. An array containing information about the service account user. User details include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Username</td><td>Required. A string indicating the short name of the SSH service account user (e.g. myapp). This, together with the ClientHostname, is used to build the full user name (e.g. myapp@appsrvr75).</td></tr>
<tr><td>LogonIds</td><td>An array of integers indicating the Keyfactor Command reference IDs of Linux logons that should be associated with the service account in order to publish the service account's public key to the servers on which the logons are located.</td></tr>
</table>
</td></tr>
<tr><td>ClientHostname</td><td>Body</td><td>Required. A string indicating the client hostname reference for the service account key. This field is used for reference only and does not need to match an actual client hostname. It is used when building the full user name of the service account key for mapping to Linux logons for publishing to Linux servers (e.g. username@client_hostname). The naming convention is to use the host-name of the server on which the application that will use the private key resides (e.g. appsrvr12), but you can put anything you like in this field (e.g. cheesetoast).</td></tr>
</table>

Name	In	Description
ServerGroupId	Body	**Required**. A string indicating the Keyfactor Command reference GUID for the SSH server group for the service account. The server group is used to control who has access in Keyfactor Command to the service account key. It does not limit where the key can be published. See SSH Permissions on page 549 in the *Keyfactor Command Reference Guide* for more information.

Table 549: POST SSH Service Accounts Response Data

Name	Description
ID	The Keyfactor Command reference ID for the SSH service account. This ID is automatically set by Keyfactor Command.
ClientHostname	A string indicating the client hostname reference for the service account key. This field is used for reference only and does not need to match an actual client hostname. It is used when building the full user name of the service account key for mapping to Linux logons for publishing to Linux servers (e.g. username@client_hostname). The naming convention is to enter the hostname of the server on which the application that will use the private key resides (e.g. appsrvr12), but you can put anything you like in this field (e.g. cheesetoast).
ServerGroup	An array that indicates the SSH server group for the service account. The server group is used to control who has access in Keyfactor Command to the service account key. It does not limit where the key can be published. See SSH Permissions on page 549 in the *Keyfactor Command Reference Guide* for more information. Server group information includes:

Name	Description
Id	A string indicating the Keyfactor Command reference GUID of the SSH server group.
Owner	An object indicating the Active Directory user who owns the server group. See SSH Server Groups on page 513 in the *Keyfactor Command Reference Guide* for more information.

Name	Description
Id	An integer indicating the Keyfactor Command reference ID of the *user* who holds the owner role on the SSH server group.

GroupName	A string indicating the name of the SSH server group.
SyncSchedule	An array providing the inventory schedule for the SSH server group. The schedule can be off (unset) or one of the supported values. Supported schedule values are:

Name	Description
Off	Turn off a previously configured schedule.

Name	Description
	Name / **Description**

Name / **Description**

Name	Description
Interval	A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database. **Name** / **Description** Minutes — An integer indicating the number of minutes between each interval. For example, every hour: `"Interval": { "Minutes": 60 }`
Daily	A dictionary that indicates a job scheduled to run every day at the same time with the parameter: **Name** / **Description** Time — The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z). For example, daily at 11:30 pm: `"Daily": { "Time": "2022-02-25T23:30:00Z" }`
Weekly	A dictionary that indicates a job scheduled to run on a specific day or days every week at the same time with the parameters:

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
<tr><td>Days</td><td>An array of values representing the days of the week on which to run the job. These can either be entered as integers (0 for Sunday, 1 for Monday, etc.) or as days of the week (e.g. "Sunday").</td></tr>
</table>
For example, every Monday, Wednesday and Friday at 5:30 pm:
<pre>"Weekly": {
   "Days": [
      "Monday",
      "Wednesday",
      "Friday"
   ],
   "Time": "2022-02-27T17:30:00Z"
}</pre>
</td></tr>
<tr><td>Monthly</td><td>A dictionary that indicates a job scheduled to run on a specific day or days every month at the same time with the parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
<tr><td>Day</td><td>The number of the day, in the month, to run the job.</td></tr>
</table>
For example, on the first of every month at 5:30 pm:
</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td><pre>"Monthly": {
   "Day": 1
   "Time": "2022-02-27T17:30:00Z"
}</pre></td></tr>
</table>
Note: Although the Swagger Example Value may show examples of various other schedules, only the schedules shown here—that are available in the Management Portal for this functionality—are valid for this endpoint.
</td></tr>
<tr><td>Under-Management</td><td>A Boolean indicating whether the SSH server group is in inventory only mode (False) or inventory and publish policy mode (True).</td></tr>
</table>
</td></tr>
<tr><td>User</td><td>An array containing information about the service account user. Service account user details include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of the SSH service account user.</td></tr>
<tr><td>Key</td><td>An array containing information about the key for the service account user. Key details include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of the SSH service account's key.</td></tr>
<tr><td>Fingerprint</td><td>A string indicating the fingerprint of the public key. Each SSH public key has a single cryptographic fingerprint that can be used to uniquely identify the key.</td></tr>
<tr><td>PublicKey</td><td>A string indicating the public key of the key pair for the SSH service account.</td></tr>
<tr><td>KeyType</td><td>A string indicating the cryptographic algorithm used to</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>generate the SSH key. Possible values are:
RSA
ECDSA
Ed25519</td></tr>
<tr><td>KeyLength</td><td>An integer indicating the key length for the SSH key. The key length supported depends on the key type selected. Keyfactor Command supports 256 bits for Ed25519 and ECDSA and 2048 or 4096 bits for RSA.</td></tr>
<tr><td>CreationDate</td><td>The date, in UTC, on which the SSH key pair was created.</td></tr>
<tr><td>StaleDate</td><td>The date, in UTC, after which the SSH key pair is considered to be out of date based on the key lifetime defined by the Key Lifetime (days) application setting. See Application Settings: SSH Tab on page 572 in the Keyfactor Command Reference Guide for more information.</td></tr>
<tr><td>Email</td><td>A string containing the email address of the administrator or group of administrators responsible for managing the key. This email address is used to alert the administrator or group of administrators when the key pair is approaching the end of its lifetime.</td></tr>
<tr><td>Comments</td><td>An array containing one or more strings with the user-defined descriptive comments, if any, on the key. Although entry of an email address in the comment field of an SSH key is traditional, this is not a required format. The comment may can contain any characters supported for string fields, including spaces and most punctuation marks. Keys created through the Keyfactor Command Management Portal or with the POST /SSH/ServiceAccounts method will contain only one string in the array.</td></tr>
<tr><td>LogonCount</td><td>An integer indicating the number of Linux logons associated with the SSH key pair.</td></tr>
</table>
</td></tr>
</table>
</td></tr>
<tr><td>Username</td><td>A string indicating the full username of the service account. The username is made up of the user name and ClientHostname entered when the service account is created (e.g. myapp@appsrvr75).</td></tr>
</table>

Name	Description
LogonIds	An array of integers indicating the Keyfactor Command reference IDs of Linux logons that are associated with the service account in order to publish the service account's public key to the servers on which the logons are located.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

PUT SSH Service Accounts

The PUT /SSH/ServiceAccounts method is used to update an existing SSH service account in Keyfactor Command. This method returns HTTP 200 OK on a success with details for the SSH service account.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group with which the key is associated and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Warning: Any previously populated fields that are not submitted with their full existing data using this method will be cleared of their existing data. When using this method, you should first do a GET to retrieve all the values for the record you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing.

Table 550: PUT SSH Service Accounts Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>KeyUpdateRequest</td><td>Body</td><td>Required. An array that sets the information to include in the SSH service account key update request. Key update request information includes:<table><tr><th>Name</th><th>Description</th></tr><tr><td>Id</td><td>Required. The Keyfactor Command reference ID for the service account's key.</td></tr><tr><td>Email</td><td>Required. A string containing the email address of the administrator or group of administrators responsible for managing the key. This email address is used to alert the administrator or group of administrators when the key pair is approaching the end of its lifetime.</td></tr><tr><td>Comment</td><td>An string containing the user-defined descriptive comment, if any, on the key. Although entry of an email address in the comment field of an SSH key is traditional, this is not a required format. The comment may can contain any characters supported for string fields, including spaces and most punctuation marks.</td></tr></table></td></tr>
<tr><td>Id</td><td>Body</td><td>Required. The Keyfactor Command reference ID for the service account. Use the GET /SSH/ServiceAccounts method (see GET SSH Service Accounts on page 1768) to retrieve a list of all the SSH service accounts to determine the service account's ID.</td></tr>
</table>

Table 551: PUT SSH Service Accounts Response Data

Name	Description
ID	The Keyfactor Command reference ID for the SSH service account. This ID is automatically set by Keyfactor Command.
ClientHostname	A string indicating the client hostname reference for the service account key. This field is used for reference only and does not need to match an actual client hostname. It is used when building the full user name of the service account key for mapping to Linux logons for publishing to Linux servers (e.g. username@client_hostname). The naming convention is to enter the hostname of the server on which the application that will use the private key resides (e.g. appsrvr12), but you can put anything you like in this field (e.g. cheesetoast).
ServerGroup	An array that indicates the SSH server group for the service account. The server group is used to control who has access in Keyfactor Command to the service account key. It does not limit where the key can be published. See SSH Permissions on page 549 in the *Keyfactor Command Reference Guide* for more information. Server group information includes:

Name	Description
Id	A string indicating the Keyfactor Command reference GUID of the SSH server group.
Owner	An object indicating the Active Directory user who owns the server group. See SSH Server Groups on page 513 in the *Keyfactor Command Reference Guide* for more information.

Name	Description
Id	An integer indicating the Keyfactor Command reference ID of the *user* who holds the owner role on the SSH server group.

Name	Description
GroupName	A string indicating the name of the SSH server group.
SyncSchedule	An array providing the inventory schedule for the SSH server group. The schedule can be off (unset) or one of the supported values. Supported schedule values are:

Name	Description
Off	Turn off a previously configured schedule.

Name	Description
	Name / **Description**
	Interval — A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.

Name	Description
Minutes	An integer indicating the number of minutes between each interval.

For example, every hour:

```
"Interval": {
   "Minutes": 60
}
```

Daily	A dictionary that indicates a job scheduled to run every day at the same time with the parameter:

Name	Description
Time	The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).

For example, daily at 11:30 pm:

```
"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}
```

Weekly	A dictionary that indicates a job scheduled to run on a specific day or days every week at the same time with the parameters:

Name	Description
	Name / **Description** Time — The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z). Days — An array of values representing the days of the week on which to run the job. These can either be entered as integers (0 for Sunday, 1 for Monday, etc.) or as days of the week (e.g. "Sunday"). For example, every Monday, Wednesday and Friday at 5:30 pm: `"Weekly": { "Days": [ "Monday", "Wednesday", "Friday" ], "Time": "2022-02-27T17:30:00Z" }` Monthly — A dictionary that indicates a job scheduled to run on a specific day or days every month at the same time with the parameters: Time — The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z). Day — The number of the day, in the month, to run the job. For example, on the first of every month at 5:30 pm:

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td><pre>"Monthly": {

<tr><td>Username</td><td>A string indicating the full username of the service account. The username is made up of the user name and ClientHostname entered when the service account is created (e.g. myapp@appsrvr75).</td></tr>
</table>

Name	Description
LogonIds	An array of integers indicating the Keyfactor Command reference IDs of Linux logons that are associated with the service account in order to publish the service account's public key to the servers on which the logons are located.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

POST SSH Service Accounts Rotate ID

The POST /SSH/ServiceAccounts/Rotate/{id} method is used to generate a new key pair in Keyfactor Command for an existing SSH service account. This method returns HTTP 200 OK on a success with details for the new key pair of the SSH service account, including the private key.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group with which the key is associated and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 552: GET SSH Service Accounts Rotate {id} Input Parameters

Name	In	Description

id	Path	**Required**. The Keyfactor Command reference ID for the SSH service account key for which to retrieve key information.
		Use the *GET /SSH/ServiceAccounts* method (see GET SSH Service Accounts on page 1768) to retrieve a list of all the SSH service accounts to determine the service account's key ID.
		
		Tip: Be sure to use the ID of the service account itself and not the ID of the service account user or service account's key within the service account. For example, notice the following record returned from a GET /SSH/ServiceAccounts:
		<pre>{
		"Id": 2,
		"ClientHostname": "appsrvr80.keyexample.com",
		"ServerGroup": {
		"Id": "603d3d4c-89dd-4ab8-92e1-8e83db3d5546",
		"GroupName": "Server Group Two",
		"UnderManagement": false
		},
		"User": {
		"Id": 7,
		"Key": {
		"Id": 36,
		"Fingerprint": "kwuo2k3Ej7wFVMLhI3g+rxt2qXwGp7qcvzdBjVTDHNg=",
		"PublicKey": "ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAABAQCAln+t [truncated for display]",
		"KeyType": "RSA",
		"KeyLength": 2048,
		"CreationDate": "2020-11-17T17:53:55.68",
		"Email": "pkiadmins@keyexample.com",
		"Comments": [
		"Access App Two"
		],
		"LogonCount": 3
		},
		"Username": "svc_access2@appsrvr80.keyexample.com"
		}
		}</pre>It contains three IDs:
		• ID 2: The service account's ID. Use this one to rotate the key.
		• ID 7: The service account user's ID.

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td> 
ID 36: The ID of the service account user's key.</td></tr>
<tr><td>KeyType</td><td>Body</td><td>Required. A string indicating the cryptographic algorithm used to generate the SSH key. Possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>1</td><td>ECDSA</td></tr>
<tr><td>2</td><td>Ed25519</td></tr>
<tr><td>3</td><td>RSA</td></tr>
</table></td></tr>
<tr><td>PrivateKeyFormat</td><td>Body</td><td>Required. A string indicating the format to use for the downloadable private key. Possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>1</td><td>OpenSSH</td></tr>
<tr><td>2</td><td>PKCS8</td></tr>
</table></td></tr>
<tr><td>KeyLength</td><td>Body</td><td>Required*. An integer indicating the key length for the SSH key. The key length supported depends on the key type selected. Keyfactor Command supports 256 bits for Ed25519 and ECDSA and 2048 or 4096 bits for RSA. This field is optional if the KeyType is set to ECDSA or Ed25519 and required if the KeyType is set to RSA.</td></tr>
<tr><td>Email</td><td>Body</td><td>Required. A string containing the email address of the administrator or group of administrators responsible for managing the key. This email address is used to alert the administrator or group of administrators when the key pair is approaching the end of its lifetime.</td></tr>
<tr><td>Password</td><td>Body</td><td>Required. A string that sets a password used to secure the private key of the SSH key pair for download.</td></tr>
<tr><td>Comment</td><td>Body</td><td>An string containing the user-defined descriptive comment, if any, on the key. Although entry of an email address in the comment field of an SSH key is traditional, this is not a required format. The comment may can contain any characters supported for string fields, including spaces and most punctuation marks.</td></tr>
</table>

Table 553: GET SSH Service Accounts Rotate {id} Response Data

Name	Description
ID	An integer indicating the Keyfactor Command reference ID for the SSH service account key. This ID is automatically set by Keyfactor Command.
Fingerprint	A string indicating the fingerprint of the public key. Each SSH public key has a single cryptographic fingerprint that can be used to uniquely identify the key.
PublicKey	A string indicating the public key of the key pair for the SSH service account.
PrivateKey	A string indicating the private key of the key pair for the SSH service account.
KeyType	A string indicating the cryptographic algorithm used to generate the SSH key. Possible values are: • RSA • ECDSA • Ed25519
KeyLength	An integer indicating the key length for the SSH key. The key length supported depends on the key type selected. Keyfactor Command supports 256 bits for Ed25519 and ECDSA and 2048 or 4096 bits for RSA.
Comments	An array containing one or more strings with the user-defined descriptive comments, if any, on the key. Although entry of an email address in the comment field of an SSH key is traditional, this is not a required format. The comment may can contain any characters supported for string fields, including spaces and most punctuation marks. Keys created through the Keyfactor Command Management Portal or with the POST /SSH/ServiceAccounts method will contain only one string in the array.
LogonCount	An integer indicating the number of Linux logons associated with the SSH key pair.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.25.6 SSH Users

The SSH Users component of the Keyfactor Web APIs includes methods necessary to retrieve, create, update, rotate, and delete users and associated keys in Keyfactor Command.

Table 554: SSH Users Endpoints

Endpoint	Method	Description	Link
/{id}	DELETE	Deletes the SSH user with the specified ID.	DELETE SSH Users ID below
/{id}	GET	Returns the SSH user with the specified ID.	GET SSH Users ID below
/	GET	Returns a list of SSH users based on the specified filters.	GET SSH Users on page 1800
/	POST	Creates a new SSH user.	POST SSH Users on page 1809
/	PUT	Updates an existing SSH user.	PUT SSH Users on page 1810
/Access	POST	Creates a mapping from the SSH user to one or more Linux logons.	POST SSH Users Access on page 1812

DELETE SSH Users ID

The DELETE /SSH/Users/{id} method is used to delete an SSH user in Keyfactor Command. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SSH: *ServerAdmin*

Table 555: DELETE SSH Users {id} Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID for the SSH user (user or service account) to be deleted. Use the *GET /SSH/Users* method (see GET SSH Users on page 1800) to retrieve a list of all the SSH users to determine the user's ID.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

GET SSH Users ID

The GET /SSH/Users/{id} method is used to retrieve an SSH user defined in Keyfactor Command.The method can return either a *user* or a *service account* See SSH on page 479 in the *Keyfactor Command Reference Guide* for more information on the difference between *users* and *service accounts*. This method returns HTTP 200 OK on a success with details for the requested SSH user and its public key. To return an SSH private key, use the GET

/SSH/Keys/MyKey method (see GET SSH Keys My Key on page 1674) for a user account or the GET /SSH/ServiceAccounts/Key/{id} method (see GET SSH Service Accounts Key ID on page 1762) for a service account.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group with which user to logon mappings are associated and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

This method has two available versions. Keyfactor recommends using the newer method when possible. For more information about versioning, see Versioning on page 721.

Version 2

Version 2 of the GET /SSH/Users/{id} method redesigns how logon information for the user is returned, providing a greater level of detail in the returned data.

Table 556: GET SSH Users {id} v2 Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID for the SSH user (user or service account) to be retrieved. Use the *GET /SSH/Users* method (see GET SSH Users on page 1800) to retrieve a list of all the SSH users to determine the user's ID.

Table 557: GET SSH Users {id} v2 Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of the SSH user.</td></tr>
<tr><td>Key</td><td>An array containing information about the key for the user. Key details include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of the SSH user's key.</td></tr>
<tr><td>Fingerprint</td><td>A string indicating the fingerprint of the public key. Each SSH public key has a single cryptographic fingerprint that can be used to uniquely identify the key.</td></tr>
<tr><td>PublicKey</td><td>A string indicating the public key of the key pair for the SSH user.</td></tr>
<tr><td>KeyType</td><td>A string indicating the cryptographic algorithm used to generate the SSH key. Possible values are:
RSA
ECDSA
Ed25519</td></tr>
<tr><td>KeyLength</td><td>An integer indicating the key length for the SSH key. The key length supported depends on the key type selected. Keyfactor Command supports 256 bits for Ed25519 and ECDSA and 2048 or 4096 bits for RSA.</td></tr>
<tr><td>CreationDate</td><td>The date, in UTC, on which the SSH key pair was created.</td></tr>
<tr><td>StaleDate</td><td>The date, in UTC, after which the SSH key pair is considered to be out of date based on the key lifetime defined by the Key Lifetime (days) application setting. See Application Settings: SSH Tab on page 572 in the Keyfactor Command Reference Guide for more information.</td></tr>
<tr><td>Email</td><td>A string containing the email address of the user, for user accounts, or administrator or group of administrators responsible for managing the key, for service accounts. This email address is used to alert the user or administrator when the key pair is approaching the end of its lifetime.</td></tr>
<tr><td>Comments</td><td>An array containing one or more strings with the user-defined descriptive comments, if any, on the key. Although entry of an email address in the comment field of an SSH key is traditional, this is not a required format. The comment may can contain any characters supported for string fields, including spaces and most punctuation marks. Keys created through the Keyfactor Command Management Portal or with the POST /SSH/Keys/MyKey or POST</td></tr>
</table></td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>/SSH/ServiceAccounts method will contain only one string in the array.</td></tr>
<tr><td>LogonCount</td><td>An integer indicating the number of Linux logons associated with the SSH key pair.</td></tr>
</table>
</td></tr>
<tr><td>Username</td><td>A string indicating the full username of the user or service account. For a user account, the username appears in DOMAIN\\username format (e.g. KEYEXAMPLE\\jsmith). For a service account, the username is made up of the user name and ClientHostname entered when the service account is created (e.g. myapp@appsrvr75).</td></tr>
<tr><td>Access</td><td>An array containing information about the Linux logons mapped to the user. Linux logon mapping details include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of the Linux logon.</td></tr>
<tr><td>KeyCount</td><td>An integer indicating the number of SSH keys associated with the Linux logon.</td></tr>
<tr><td>Access</td><td>An array containing information about the users mapped to the Linux logon.</td></tr>
</table>
</td></tr>
<tr><td>IsGroup</td><td>A Boolean indicating whether the user is an Active Directory group (true) or not (false).</td></tr>
</table>

Version 1

Version 1 of the GET /SSH/Users/{id} method includes the same capabilities as version 2, but offers more limited information on returned logons for the user.

Table 558: GET SSH Users {id} v1 Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference ID for the SSH user (user or service account) to be retrieved. Use the *GET /SSH/Users* method (see GET SSH Users on page 1800) to retrieve a list of all the SSH users to determine the user's ID.

Table 559: GET SSH Users {id} v1 Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of the SSH user.</td></tr>
<tr><td>Key</td><td>An array containing information about the key for the user. Key details include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of the SSH user's key.</td></tr>

<tr><td>LogonIds</td><td>An array of Keyfactor Command reference IDs for the Linux logons mapped to the user to cause the user's SSH public key to be published out to the Linux servers on which those logons reside.</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

GET SSH Users

The GET /SSH/Users method is used to retrieve one or more SSH users defined in Keyfactor Command. The method returns both *users* and *service accounts*. See SSH on page 479 in the *Keyfactor Command Reference Guide* for more information on the difference between *users* and *service accounts*. Results can be limited to selected users using filtering, and URL parameters can be used to specify paging and the level of information detail. This method returns HTTP 200 OK on a success with details for the requested SSH users and their public keys. To return the SSH private key, use the GET /SSH/Keys/MyKey method (see GET SSH Keys My Key on page 1674) for user accounts and the GET /SSH/ServiceAccounts/Key/{id} method (see GET SSH Service Accounts Key ID on page 1762) for service accounts.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group with which user to logon mappings are associated and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

This method has two available versions. Keyfactor recommends using the newer method when possible. For more information about versioning, see Versioning on page 721.

Version 2

Version 2 of the GET /SSH/Users method redesigns how logon information for the user is returned, providing a greater level of detail in the returned data.

Table 560: GET SSH Users v2 Input Parameters

Name	In	Description
showOwnedAccess	Query	A Boolean that specifies whether to return only users that have logons on servers that the requesting user owns (*true*) or not (*false*). The default is *false*. This option applies only to requesting users with *SSH User* or *SSH Server Admin* permissions; users with *SSH Enterprise Admin* permissions will see all users regardless of the configuration of this setting. Use the *GET /SSH/Servers* method (see GET SSH Servers on page 1702) or the *GET /SSH/ServerGroups* method (see GET SSH Server Groups on page 1731) to determine ownership of a server or server group.  **Example:** Example Scenario One • Server A is owned by Gina and server B is owned by John. • Gina is an *SSH Server Admin* but not an *SSH Enterprise Admin*. • Dave has a logon on server B but not on server A. Gina does a GET /SSH/Users with *showOwnedAccess=false* and looks at the results for Dave's user record. She sees Dave's user record, but sees no specific logon information for Dave (other than the LogonCount), because all Dave's logons are on servers that Gina does not own. Gina does a GET /SSH/Users with *showOwnedAccess=true* and looks at the results for Dave's user record. Dave's user record does not appear. The presence or absence of Dave's user record is controlled by *showOwnedAccess*. The presence or absence of logon information associated with Dave's user record is controlled by Gina's level of SSH permissions—with *SSH Server Admin* permissions, Gina will always see only logons for servers that she owns.  **Example:** Example Scenario Two • Server A is owned by Gina and server B is owned by John. • Gina is an *SSH Server Admin* but not an *SSH Enterprise Admin*. • Dave has a logon on server B and a logon on server A. Gina does a GET /SSH/Users with *showOwnedAccess=false* and looks at the results for Dave's user record. She sees Dave's user record and she sees logon information for server A, but no logon information for server B. Because Gina does not own server B, logon information for that server is not visible to her. Gina does a GET /SSH/Users with *showOwnedAccess=true* and looks at the results for Dave's user record. She sees Dave's user record and she sees logon information for server A, but no logon information for server B. Because Gina does not own server B, logon information for that server is not visible to her.

Name	In	Description
		Notice there is no difference here in the results whether you choose *true* or *false* because at least one logon for Dave is present on a server owned by Gina. The *showOwnedAccess* option only comes into play when a user has no logons on a server owned by the requesting user. The presence or absence of logon information associated with Dave's user record is controlled by Gina's level of SSH permissions—with *SSH Server Admin* permissions, Gina will always see only logons for servers that she owns.
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Using the SSH Server Search on page 535. The query fields supported for this endpoint are: • *Email* • *Fingerprint* • *IsServiceAccount* • *KeyLength* • *KeyType* • *LogonCount* • *LogonServerGroupId* • *LogonServerId* • *ServiceAccountId* • *StaleDate* • *Username*
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *Username*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 561: GET SSH Users v2 Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of the SSH user.</td></tr>
<tr><td>Key</td><td>An array containing information about the key for the user. Key details include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of the SSH user's key.</td></tr>
<tr><td>Fingerprint</td><td>A string indicating the fingerprint of the public key. Each SSH public key has a single cryptographic fingerprint that can be used to uniquely identify the key.</td></tr>
<tr><td>PublicKey</td><td>A string indicating the public key of the key pair for the SSH user.</td></tr>
<tr><td>KeyType</td><td>A string indicating the cryptographic algorithm used to generate the SSH key. Possible values are:
RSA
ECDSA
Ed25519</td></tr>
<tr><td>KeyLength</td><td>An integer indicating the key length for the SSH key. The key length supported depends on the key type selected. Keyfactor Command supports 256 bits for Ed25519 and ECDSA and 2048 or 4096 bits for RSA.</td></tr>
<tr><td>CreationDate</td><td>The date, in UTC, on which the SSH key pair was created.</td></tr>
<tr><td>StaleDate</td><td>The date, in UTC, after which the SSH key pair is considered to be out of date based on the key lifetime defined by the Key Lifetime (days) application setting. <tr><td>Access</td><td>An array containing information about the Linux logons mapped to the user. Linux logon mapping details include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of the Linux logon.</td></tr>
<tr><td>KeyCount</td><td>An integer indicating the number of SSH keys associated with the Linux logon.</td></tr>
<tr><td>Access</td><td>An array containing information about the users mapped to the Linux logon.</td></tr>
</table>
</td></tr>
<tr><td>IsGroup</td><td>A Boolean indicating whether the user is an Active Directory group (true) or not (false).</td></tr>
</table>

Version 1

Version 1 of the GET /SSH/Users method includes the same capabilities as version 2, but offers more limited information on returned logons for the user.

Table 562: GET SSH Users v1 Input Parameters

Name	In	Description
showOwnedAccess	Query	A Boolean that specifies whether to return only users that have logons on servers that the requesting user owns (*true*) or not (*false*). The default is *false*. This option applies only to requesting users with *SSH User* or *SSH Server Admin* permissions; users with *SSH Enterprise Admin* permissions will see all users regardless of the configuration of this setting. Use the *GET /SSH/Servers* method (see GET SSH Servers on page 1702) or the *GET /SSH/ServerGroups* method (see GET SSH Server Groups on page 1731) to determine ownership of a server or server group.  **Example:** Example Scenario One • Server A is owned by Gina and server B is owned by John. • Gina is an *SSH Server Admin* but not an *SSH Enterprise Admin*. • Dave has a logon on server B but not on server A. Gina does a GET /SSH/Users with *showOwnedAccess=false* and looks at the results for Dave's user record. She sees Dave's user record, but sees no specific logon information for Dave (other than the LogonCount), because all Dave's logons are on servers that Gina does not own. Gina does a GET /SSH/Users with *showOwnedAccess=true* and looks at the results for Dave's user record. Dave's user record does not appear. The presence or absence of Dave's user record is controlled by *showOwnedAccess*. The presence or absence of logon information associated with Dave's user record is controlled by Gina's level of SSH permissions—with *SSH Server Admin* permissions, Gina will always see only logons for servers that she owns.  **Example:** Example Scenario Two • Server A is owned by Gina and server B is owned by John. • Gina is an *SSH Server Admin* but not an *SSH Enterprise Admin*. • Dave has a logon on server B and a logon on server A. Gina does a GET /SSH/Users with *showOwnedAccess=false* and looks at the results for Dave's user record. She sees Dave's user record and she sees logon information for server A, but no logon information for server B. Because Gina does not own server B, logon information for that server is not visible to her. Gina does a GET /SSH/Users with *showOwnedAccess=true* and looks at the results for Dave's user record. She sees Dave's user record and she sees logon information for server A, but no logon information for server B. Because Gina does not own server B, logon information for that server is not visible to her.

Name	In	Description
		Notice there is no difference here in the results whether you choose *true* or *false* because at least one logon for Dave is present on a server owned by Gina. The *showOwnedAccess* option only comes into play when a user has no logons on a server owned by the requesting user. The presence or absence of logon information associated with Dave's user record is controlled by Gina's level of SSH permissions—with *SSH Server Admin* permissions, Gina will always see only logons for servers that she owns.

</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

POST SSH Users

The POST /SSH/Users method is used to create a new SSH user in Keyfactor Command and, optionally, associate the user with one or more Linux logons during creation to allow the public key for the user to be published out to a Linux server—for servers in *inventory and publish policy* mode. This method returns HTTP 200 OK on a success with the details of the user to logon mapping, if any.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group with which user to logon mappings are associated and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 564: POST SSH Users Input Parameters

Name	In	Description
Username	Body	**Required**. A string indicating the full username of the *user* or *service account*. For a *user* account, the username is given in DOMAIN\\username format (e.g. KEYEXAMPLE\\jsmith). For a *service account*, the username is made up of a user name (e.g. svc_myapp) and client hostname reference for the service account. The client hostname is used for reference only and does not need to match an actual client hostname. The naming convention is to enter the hostname of the server on which the application that will use the private key resides (e.g. appsrvr12), but you can put anything you like in this field (e.g. cheesetoast). The full service account name is given in the form username@clienthostname (e.g. svc_myapp@appsrvr75).
LogonIds	Body	An array of Keyfactor Command reference IDs for the Linux logons to map to the user to cause the user's SSH public key to be published out to the Linux servers on which those logons reside. These are provided in the following format: `[12,27,39]` Use the *GET /SSH/Logons* method (see GET SSH Logons on page 1689) to retrieve a list of all the SSH logons to determine the logon's ID(s).

Table 565: POST SSH Users Response Data

Name	Description
ID	An integer indicating the Keyfactor Command reference ID of the SSH user.
Username	A string indicating the full username of the *user* or *service account*.
LogonIds	An array of Keyfactor Command reference IDs for the Linux logons to map to the user to cause the user's SSH public key to be published out to the Linux servers on which those logons reside.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

PUT SSH Users

The PUT /SSH/Users method is used to update an existing SSH user in Keyfactor Command and, optionally, associate the user with one or more Linux logons to allow the public key for the user to be published out to a Linux server—for servers in *inventory and publish policy* mode. This method returns HTTP 200 OK on a success with the details of the user to logon mapping, if any.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group with which user to logon mappings are associated and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Table 566: PUT SSH Users Input Parameters

Name	In	Description
ID	Body	**Required**. An integer indicating the Keyfactor Command reference ID of the SSH user. Use the *GET /SSH/Users* method (see GET SSH Users on page 1800) to retrieve a list of all the SSH users to determine the user's ID.
LogonIds	Body	An array of Keyfactor Command reference IDs for the Linux logons to map to the user to cause the user's SSH public key to be published out to the Linux servers on which those logons reside. These are provided in the following format: `[12,27,39]` Use the *GET /SSH/Logons* method (see GET SSH Logons on page 1689) to retrieve a list of all the SSH logons to determine the logon's ID(s). **Important:** Logon IDs you provide here replace any existing logon IDs associated with the user. To avoid accidentally removing access for users, check existing logons for the user (see GET SSH Users on page 1800) before updating and provide both existing and new logon IDs.

Table 567: POST SSH Users Response Data

Name	Description
ID	An integer indicating the Keyfactor Command reference ID of the SSH user.
Username	A string indicating the full username of the *user* or *service account*.
LogonIds	An array of Keyfactor Command reference IDs for the Linux logons to map to the user to cause the user's SSH public key to be published out to the Linux servers on which those logons reside.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

POST SSH Users Access

The POST /SSH/Users/Access method is used to create a mapping of one or more Linux logons to a Keyfactor Command user or service account. This method returns HTTP 200 OK on a success with the details of the user to logon mapping, if any.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SSH: *ServerAdmin* OR
SSH: *EnterpriseAdmin*

SSH actions are affected by ownership on the server group with which user to logon mappings are associated and limited for users with only the *ServerAdmin* role. For more information, see SSH Permissions on page 549 in the *Keyfactor Command Reference Guide*.

Tip: Before creating a logon to user mapping, be sure that you have switched the server to which you will add your mapping (or its server group) to *inventory and publish policy* mode so that the key for the user will be published to the server. If the server is in *inventory only* mode and you add a mapping for it in Keyfactor Command, the mapping will appear in Keyfactor Command only and the key for the user will not be published out to the server.

Table 568: POST SSH Users Access Input Parameters

Name	In	Description
ID	Body	**Required**. An integer indicating the Keyfactor Command reference ID of the SSH user. Use the *GET /SSH/Users* method (see GET SSH Users on page 1800) to retrieve a list of all the SSH users to determine the user's ID.
LogonIds	Body	An array of Keyfactor Command reference IDs for the Linux logons to map to the user to cause the user's SSH public key to be published out to the Linux servers on which those logons reside. These are provided in the following format: `[12,27,39]` Use the *GET /SSH/Logons* method (see GET SSH Logons on page 1689) to retrieve a list of all the SSH logons to determine the logon's ID(s). **Important:** Logon IDs you provide here replace any existing logon IDs associated with the user. To avoid accidentally removing access for users, check existing logons for the user (see GET SSH Users on page 1800) before updating and provide both existing and new logon IDs.

Table 569: POST SSH Users Access Response Data

Name	Description
Id	An integer indicating the Keyfactor Command reference ID of the SSH user.
Key	An array containing information about the key for the user. Key details include: **Name** / **Description** Id — An integer indicating the Keyfactor Command reference ID of the SSH user's key. Fingerprint — A string indicating the fingerprint of the public key. Each SSH public key has a single cryptographic fingerprint that can be used to uniquely identify the key. PublicKey — A string indicating the public key of the key pair for the SSH user. KeyType — A string indicating the cryptographic algorithm used to generate the SSH key. Possible values are: • RSA • ECDSA • Ed25519 KeyLength — An integer indicating the key length for the SSH key. The key length supported depends on the key type selected. Keyfactor Command supports 256 bits for Ed25519 and ECDSA and 2048 or 4096 bits for RSA. CreationDate — The date, in UTC, on which the SSH key pair was created. StaleDate — The date, in UTC, after which the SSH key pair is considered to be out of date based on the key lifetime defined by the *Key Lifetime (days)* application setting. See Application Settings: SSH Tab on page 572 in the *Keyfactor Command Reference Guide* for more information. Email — A string containing the email address of the user, for user accounts, or administrator or group of administrators responsible for managing the key, for service accounts. This email address is used to alert the user or administrator when the key pair is approaching the end of its lifetime. Comments — An array containing one or more strings with the user-defined descriptive comments, if any, on the key. Although entry of an email address in the comment field of an SSH key is traditional, this is not a required format. The comment may can contain any characters supported for string fields, including spaces and most punctuation marks. Keys created through the Keyfactor Command Management Portal or with the *POST /SSH/Keys/MyKey* or *POST*

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>/SSH/ServiceAccounts method will contain only one string in the array.</td></tr>
<tr><td>LogonCount</td><td>An integer indicating the number of Linux logons associated with the SSH key pair.</td></tr>
</table>
</td></tr>
<tr><td>Username</td><td>A string indicating the full username of the user or service account. For a user account, the username appears in DOMAIN\\username format (e.g. KEYEXAMPLE\\jsmith). For a service account, the username is made up of the user name and ClientHostname entered when the service account is created (e.g. myapp@appsrvr75).</td></tr>
<tr><td>Access</td><td>An array containing information about the Linux logons mapped to the user. Linux logon mapping details include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of the Linux logon.</td></tr>
<tr><td>Username</td><td>A string indicating the user's logon name on the Linux server.</td></tr>
<tr><td>KeyCount</td><td>An integer indicating the number of SSH keys associated with the Linux logon.</td></tr>
<tr><td>Access</td><td>An array containing information about the users mapped to the Linux logon.</td></tr>
</table>
</td></tr>
<tr><td>IsGroup</td><td>A Boolean indicating whether the user is an Active Directory group (true) or not (false).</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.26 SMTP

The SMTP component of the Keyfactor API includes methods necessary to programmatically edit and retrieve the SMTP configuration profile and send a test email message. Editing the SMTP configuration profile in Keyfactor Command will only apply within the software. Only one SMTP profile may be configured.

Table 570: SMTP Endpoints

Endpoint	Method	Description	Link
/	GET	Returns information about the SMTP configuration profile.	GET SMTP on the next page

Endpoint	Method	Description	Link
/	PUT	Updates settings for the SMTP configuration profile.	PUT SMTP on page 1817
/Test	POST	Sends a test email message to confirm SMTP configuration.	POST SMTP Test on page 1819

3.2.26.1 GET SMTP

The GET /SMTP method is used to retrieve the SMTP configuration profile from Keyfactor Command. This method returns HTTP 200 OK on a success with details about the SMTP profile. Only one profile may be configured. There are no input parameters for this method.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SystemSettings: *Read*

Table 571: GET SMTP Response Data

Name	Description
Host	A string indicating the fully qualified domain name of your SMTP host (e.g. corpexch02.keyexample.com).
Id	An integer indicating the Keyfactor Command reference ID of the SMTP record. This will be 1 in most environments.
Port	An integer indicating the SMTP port (e.g. 25).
RelayAuthenticationType	An integer indicating the type of authentication used to connect to the mail server. Possible values are: **Value** / **Description** 0 – Anonymous 2 – Explicit Credentials
RelayUsername	A string indicating the username of the account providing authentication to the mail server if *RelayAuthenticationType* is set to 2. The username should be provided in DOMAIN\\username format. For most mail server configurations, the username provided must have as a valid email address the email address you set in the *SenderAccount* parameter.
SenderAccount	A string indicating the sender for email messages delivered from Keyfactor Command, in the form of an email address (e.g. jsmith@keyexample.com). Depending on the email configuration in your environment, the sender account may need to be a valid user on your mail server or you may be able to put anything in this field.
SenderAddress	A string indicating the sender for email messages delivered from Keyfactor Command, in the form of an email address (e.g. jsmith@keyexample.com). This is considered deprecated and may be removed in a future release.
SenderName	A string indicating the name that appears as the "from" in the user's mail client (e.g. "Keyfactor Command"). This value is used for both configurations of *RelayAuthenticationType*.
UseSSL	A Boolean indicating that mail should be delivered over TLS/SSL. Not all mail servers support this.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.26.2 PUT SMTP

The PUT /SMTP method is used to update the SMTP configuration profile information. This method returns HTTP 200 OK on a success with details about the SMTP configuration profile.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SystemSettings: *Modify*

Warning: Any previously populated fields that are not submitted with their full existing data using this method will be cleared of their existing data. When using this method, you should first do a GET to retrieve all the values for the record you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing.

Table 572: PUT SMTP Input Parameters

Name	In	Description
Host	Body	**Required**. A string indicating the fully qualified domain name of your SMTP host (e.g. corpexch02.keyexample.com).
Id	Body	**Required**. An integer indicating the Keyfactor Command reference ID of the SMTP record. This will be 1 in most environments.
Port	Body	An integer indicating the SMTP port (e.g. 25).
RelayAuthenticationType	Body	An integer indicating the type of authentication used to connect to the mail server. Possible values are: **Value** / **Description** 0 — Anonymous 2 — Explicit Credentials
RelayPassword	Body	**Required***. A string indicating the password of the user specified by *RelayUsername* if *RelayAuthenticationType* is set to 2. This field is **required** if *RelayAuthenticationType* is set to 2. No data is output in this field on a GET.
RelayUsername	Body	**Required***. A string indicating the username of the account providing authentication to the mail server if *RelayAuthenticationType* is set to 2. The username should be provided in DOMAIN\\username format. This field is **required** if *RelayAuthenticationType* is set to 2. For most mail server configurations, the username provided must have as a valid email address the email address you set in the *SenderAccount* parameter.
SenderAccount	Body	**Required**. A string indicating the sender for email messages delivered from Keyfactor Command, in the form of an email address (e.g. jsmith@keyexample.com). Depending on the email configuration in your environment, the sender account may need to be a valid user on your mail server or you may be able to put anything in this field.
SenderName	Body	**Required**. A string indicating the name that appears as the "from" in the user's mail client (e.g. "Keyfactor Command"). This value is used for both configurations of *RelayAuthenticationType*.
UseSSL	Body	A Boolean indicating that mail should be delivered over TLS/SSL. Not all mail servers support this.

Table 573: POST SMTP Test Response Data

Name	Description
Host	A string indicating the fully qualified domain name of your SMTP host (e.g. corpexch02.keyexample.com).
Id	An integer indicating the Keyfactor Command reference ID of the SMTP record. This will be 1 in most environments.
Port	An integer indicating the SMTP port (e.g. 25).
RelayAuthenticationType	An integer indicating the type of authentication used to connect to the mail server. Possible values are: **Value** / **Description** 0 / Anonymous 2 / Explicit Credentials
RelayUsername	A string indicating the username of the account providing authentication to the mail server if *RelayAuthenticationType* is set to 2. The username should be provided in DOMAIN\\username format. For most mail server configurations, the username provided must have as a valid email address the email address you set in the *SenderAccount* parameter.
SenderAccount	A string indicating the sender for email messages delivered from Keyfactor Command, in the form of an email address (e.g. jsmith@keyexample.com). Depending on the email configuration in your environment, the sender account may need to be a valid user on your mail server or you may be able to put anything in this field.
SenderName	A string indicating the name that appears as the "from" in the user's mail client (e.g. "Keyfactor Command"). This value is used for both configurations of *RelayAuthenticationType*.
UseSSL	A Boolean indicating that mail should be delivered over TLS/SSL. Not all mail servers support this.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.26.3 POST SMTP Test

The POST /SMTP/Test method is used to test the SMTP settings by sending a test email message. This method returns HTTP 200 OK on a success with details about the SMTP profile.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SystemSettings: *Modify*

Table 574: POST SMTP Test Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>Host</td><td>Body</td><td>Required. A string indicating the fully qualified domain name of your SMTP host (e.g. corpexch02.keyexample.com).</td></tr>
<tr><td>Id</td><td>Body</td><td>An integer indicating the Keyfactor Command reference ID of the SMTP record. This will be 1 in most environments.</td></tr>
<tr><td>Port</td><td>Body</td><td>Required. An integer indicating the SMTP port (e.g. 25).</td></tr>
<tr><td>RelayAuthenticationType</td><td>Body</td><td>An integer indicating the type of authentication used to connect to the mail server. Possible values are:<table><tr><th>Value</th><th>Description</th></tr><tr><td>0</td><td>Anonymous</td></tr><tr><td>2</td><td>Explicit Credentials</td></tr></table></td></tr>
<tr><td>RelayPassword</td><td>Body</td><td>Required*. A string indicating the password of the user specified by RelayUsername if RelayAuthenticationType is set to 2. This field is required if RelayAuthenticationType is set to 2.
No data is output in this field on a GET.</td></tr>
<tr><td>RelayUsername</td><td>Body</td><td>Required*. A string indicating the username of the account providing authentication to the mail server if RelayAuthenticationType is set to 2. The username should be provided in DOMAIN\\username format. This field is required if RelayAuthenticationType is set to 2.
For most mail server configurations, the username provided must have as a valid email address the email address you set in the SenderAccount parameter.</td></tr>
<tr><td>SenderAccount</td><td>Body</td><td>Required. A string indicating the sender for email messages delivered from Keyfactor Command, in the form of an email address (e.g. jsmith@keyexample.com). Depending on the email configuration in your environment, the sender account may need to be a valid user on your mail server or you may be able to put anything in this field.</td></tr>
<tr><td>SenderAddress</td><td>Body</td><td>A string indicating the sender for email messages delivered from Keyfactor Command, in the form of an email address (e.g. jsmith@keyexample.com).
This is considered deprecated and may be removed in a future release.</td></tr>
<tr><td>SenderName</td><td>Body</td><td>A string indicating the name that appears as the "from" in the user's mail client (e.g. "Keyfactor Command"). This value is used for both configurations of RelayAuthenticationType.</td></tr>
</table>

Name	In	Description
TestRecipient	Body	**Required**. A string indicating the recipient name, in email format (e.g. mjones@keyexample.com), for a test message to be sent using the SMTP configuration to confirm functionality.
UseSSL	Body	A Boolean indicating that mail should be delivered over TLS/SSL. Not all mail servers support this.

Table 575: POST SMTP Test Response Data

Name	Description
Host	A string indicating the fully qualified domain name of your SMTP host (e.g. corpexch02.keyexample.com).
Id	An integer indicating the Keyfactor Command reference ID of the SMTP record. This will be 1 in most environments.
Port	An integer indicating the SMTP port (e.g. 25).
RelayAuthenticationType	An integer indicating the type of authentication used to connect to the mail server. Possible values are: **Value** / **Description** 0 – Anonymous 2 – Explicit Credentials
RelayUsername	A string indicating the username of the account providing authentication to the mail server if *RelayAuthenticationType* is set to 2. The username should be provided in DOMAIN\\username format. For most mail server configurations, the username provided must have as a valid email address the email address you set in the *SenderAccount* parameter.
SenderAccount	A string indicating the sender for email messages delivered from Keyfactor Command, in the form of an email address (e.g. jsmith@keyexample.com). Depending on the email configuration in your environment, the sender account may need to be a valid user on your mail server or you may be able to put anything in this field.
SenderName	A string indicating the name that appears as the "from" in the user's mail client (e.g. "Keyfactor Command"). This value is used for both configurations of *RelayAuthenticationType*.
TestRecipient	A string indicating the recipient name, in email format (e.g. mjones@keyexample.com), for a test message to be sent using the SMTP configuration to confirm functionality.
UseSSL	A Boolean indicating that mail should be delivered over TLS/SSL. Not all mail servers support this.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.27 SSL

The SSL component of the Keyfactor API includes methods necessary to programmatically create, delete, edit, and list SSL networks, network ranges, and endpoints found in an SSL scan.

Table 576: SSL Endpoints

Endpoint	Method	Description	Link
/Parts/{id}	GET	Returns detailed information about a scan job for SSL discovery or monitoring.	GET SSL Parts ID on the next page
/Endpoints/{id}	GET	Returns the details about a single endpoint discovered during SSL scanning.	GET SSL Endpoints ID on page 1828
/NetworkRanges/{id}	DELETE	Removes all network ranges from the specified SSL network.	DELETE SSL NetworkRanges ID on page 1829
/NetworkRanges/{id}	GET	Returns network range information about the specified SSL network.	GET SSL NetworkRanges ID on page 1830
/Networks/{identifier}	GET	Returns information about the specified SSL network.	GET SSL Networks Identifier on page 1831
/	GET	Returns the results of an SSL scan based on query information.	GET SSL on page 1839
/Networks	GET	Returns information about all SSL networks in Keyfactor Command.	GET SSL Networks on page 1841
/Networks	POST	Creates a new SSL network.	POST SSL Networks on page 1850
/Networks	PUT	Updates an existing SSL network.	PUT SSL Networks on page 1862
/Endpoints/{id}/History	GET	Returns a list of all the SSL scanning endpoint histories for an endpoint with the given ID.	GET SSL Endpoints ID History on page 1874
/Networks/{id}/Parts	GET	Returns the scan job information for SSL discovery or monitoring.	GET SSL Networks ID Parts on page 1880
/NetworkRanges	POST	Adds network ranges to the specified SSL network.	POST SSL NetworkRanges on page 1881

Endpoint	Method	Description	Link
/NetworkRanges	PUT	Updates network range information on the specified SSL network.	PUT SSL NetworkRanges on page 1882
/Endpoints/ReviewStatus	PUT	Used to change the *reviewed* status for a given SSL endpoint.	PUT SSL Endpoints Review Status on page 1883
/Endpoints/MonitorStatus	PUT	Used to change the *monitoring* status for a given SSL endpoint.	PUT SSL Endpoints Monitor Status on page 1884
/Endpoints/ReviewAll	PUT	Used to change the *reviewed* status for all given SSL endpoints to true.	PUT SSL Endpoints Review All on page 1884
/Endpoints/MonitorAll	PUT	Used to change the *monitoring* status for all given SSL endpoints to true.	PUT SSL Endpoints Monitor All on page 1885
/Networks/{id}/Scan	POST	Starts an SSL discovery or monitoring scan job manually.	POST SSL Networks ID Scan on page 1885
/NetworkRanges/Validate	POST	Validates all SSL networks given.	POST SSL NetworkRanges Validate on page 1886
/Networks/{id}	DELETE	Removes an SSL network from Keyfactor Command.	DELETE SSL Networks ID on page 1887

3.2.27.1 GET SSL Parts ID

The GET /SSL/Parts/{id} method retrieves information for a specific job scan segment (see GET SSL Networks ID Parts on page 1880). This method returns HTTP 200 OK on a success with details about the specified scan job segment.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SslManagement: *Read*

Table 577: GET SSL Parts {id} Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference GUID for the SSL scan job segment to be retrieved. Use the *GET /SSL/Networks/{id}/Parts* method (see GET SSL Networks ID Parts on page 1880) to retrieve a list of all the scan job segments in an SSL network to determine the SSL scan job segment's GUID.

Table 578: GET SSL Parts {id} Response Data

Parameter Name	Description
ScanJobPartId	The Keyfactor Command reference GUID for the scan job segment.
LogicalScanJobId	The Keyfactor Command reference GUID for the scan job as a whole.
AgentJobId	The Keyfactor Command reference GUID for the orchestrator that ran the job segment, if applicable. If the segment has not yet started scanning, this will show all zeros.
EstimatedEndpointCount	An integer indicating the number of endpoints that will be scanned for the segment estimated in preparation for scanning. The number of endpoints per segment is configurable (see the *SSL Maximum Scan Job Size* setting on the agents tab in Application Settings: Agents Tab on page 565 in the *Keyfactor Command Reference Guide*).
Status	An integer indicating the status of the scan job segment. Possible values are: **Value** / **Description** 1 / Not Started 2 / In Progress 3 / Complete
StatTotalEndpointCount	An integer indicating the number of endpoints that were be scanned for the segment. This value will be null if the scan is not yet complete.
StatTimedOutConnectingCount	An integer indicating the number of endpoints that timed out while attempting connections. This value will be null if the scan is not yet complete.
StatConnectionRefusedCount	An integer indicating the number of endpoints that received a connection refused while attempting connections. This value will be null if the scan is not yet complete.
StatTimedOutDownloadingCount	An integer indicating the number of endpoints that timed out while downloading while attempting connections. This value will be null if the scan is not yet complete.
StatExceptionDownloadingCount	An integer indicating the number of endpoints that encountered an exception while attempting connections. This value will be null if the scan is not yet complete.
StatNotSslCount	An integer indicating the number of endpoints that made a connection and were considered not SSL (connection on a non-SSL port such as 22 or 636). This value will be null if the scan is not yet complete.

Parameter Name	Description
StatBadSslHandshakeCount	An integer indicating the number of endpoints that had a bad handshake while attempting connections. This value will be null if the scan is not yet complete.
StatCertificateFoundCount	An integer indicating the number of endpoints where a certificate was found. This value will be null if the scan is not yet complete.
StatNoCertificateCount	An integer indicating the number of endpoints where the handshake got to the part of the TLS where a certificate should be returned, but did not find a certificate.This is an uncommon occurrence, so will usually be zero.
ScanJobPartsDefinitions	This is no longer in use and will always return "null".
StartTime	The date and time at which the scan job segment started in UTC. For jobs that have not yet started, this value will be null.
EndTime	The date and time at which the scan job segment finished in UTC. For jobs that have not yet started, this value will be null.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.27.2 GET SSL Endpoints ID

The GET /SSL/Endpoints/{id} method is used to retrieve information about an endpoint found in an SSL discover or monitor scan using the EndpointId. This method returns HTTP 200 OK on a success with details of the SSL endpoints.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SslManagement: *Read*

Table 579: GET SSL Endpoints {id} Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference GUID for the SSL endpoint to be retrieved. Use the *GET /SSL* method (see GET SSL on page 1839) to retrieve a list of all the SSL endpoints to determine the SSL endpoint's GUID.

Table 580: GET SSL Endpoints {id} Response Data

Name	Description
EndpointId	The Keyfactor Command reference GUID for the endpoint.
NetworkId	The Keyfactor Command reference GUID for the SSL network that scanned the endpoint.
LastHistoryId	The Keyfactor Command reference GUID for the last history entry on the endpoint.
IpAddressBytes	The IP address for the endpoint as bytes.
Port	An integer indicating the port on which this endpoint was found.
SNIName	A string indicating the server name indication (SNI) of the endpoint, if found.
EnableMonitor	A Boolean indicating whether monitoring is enabled on this endpoint (true) or not (false).
Reviewed	A Boolean indicating whether the endpoint has been reviewed (true) or not (false).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.27.3 DELETE SSL NetworkRanges ID

The DELETE /SSL/NetworkRanges/{id} method is used to delete all the network ranges for an SSL network with the specified GUID from Keyfactor Command. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SslManagement: *Modify*

Tip: To delete some but not all of the network ranges for a network, use the *PUT /SSL/Networks* method to update the network and submit the request with only those network ranges you wish to retain (see PUT SSL Networks on page 1862).

Table 581: DELETE SSL Network Ranges {id} Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference GUID for the SSL network for which to delete network ranges. Use the *GET /SSL/Networks* method (see GET SSL Networks on page 1841) to retrieve a list of all the SSL networks to determine the SSL network's GUID.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.27.4 GET SSL NetworkRanges ID

The GET /SSL/NetworkRanges/{id} method is used to retrieve the network ranges for an SSL network with the specified GUID from Keyfactor Command. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SslManagement: *Read*

Table 582: GET SSL Network Ranges {id} Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference GUID for the SSL network for which to retrieve network ranges. Use the *GET /SSL/Networks* method (see GET SSL Networks on page 1841) to retrieve a list of all the SSL networks to determine the SSL network's GUID.

Table 583: GET SSL Network Ranges {id} Response Data

Name	Description
ItemType	An integer indicating the type of network range. Possible values are: **Value** / **Description** 0 / Unknown 1 / IP Address 2 / Host Name 3 / Network Notation
Value	A string indicating the value for the network range, including the IP address, network notation or host name followed by the port or ports for scanning (e.g. 192.168.12.0/24:443).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.27.5 GET SSL Networks Identifier

The GET /SSL/Networks/{identifier} method is used to retrieve a defined SSL network according to the provided name from Keyfactor Command. This method returns HTTP 200 OK on a success with details about the SSL network.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SslManagement: *Read*

Table 584: GET SSL Networks {id} Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference GUID for the SSL network to be retrieved. Use the *GET /SSL/Networks* method (see GET SSL Networks on page 1841) to retrieve a list of all the SSL networks to determine the SSL network's GUID.

Table 585: GET SSL Networks {id} Response Data

Name	Description
NetworkId	The Keyfactor Command reference GUID for the SSL network. This GUID is automatically set by Keyfactor Command.
Name	A string indicating the name for the SSL network.
AgentPoolName	A string indicating the name of the orchestrator pool assigned to the SSL network. See Orchestrator Pools Definition on page 434 in the *Keyfactor Command Reference Guide* for more information.
AgentPoolId	The Keyfactor Command reference GUID for the orchestrator pool assigned to the SSL network.
Description	A string indicating the description of the SSL network.
Enabled	A Boolean that indicates whether scanning is enabled for the SSL network (true) or not (false). If this is set to false, no new network scans will be scheduled but any current scan will finish if one was in progress when the status was changed from true to false.
DiscoverSchedule	An array providing the discovery schedule for the SSL network group. The schedule can be off (unset) or one of the supported values. Supported schedule values are:

Name	Description
Immediate	A Boolean that indicates a job scheduled to run immediately (true) or not (false). **Tip:** In some instances, jobs initially scheduled as *Immediate* will appear on a GET as *null*.
Interval	A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.

Name	Description
Minutes	An integer indicating the number of minutes between each interval.

For example, every hour:

```
"Interval": {
   "Minutes": 60
```

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td><pre>}</pre></td></tr>
<tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, daily at 11:30 pm:
<pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre></td></tr>
<tr><td>Weekly</td><td>A dictionary that indicates a job scheduled to run on a specific day or days every week at the same time with the parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
<tr><td>Days</td><td>An array of values representing the days of the week on which to run the job. These can either be entered as integers (0 for Sunday, 1 for Monday, etc.) or as days of the week (e.g. "Sunday").</td></tr>
</table>
For example, every Monday, Wednesday and Friday at 5:30 pm:
<pre>"Weekly": {
   "Days": [
      "Monday",
      "Wednesday",</pre></td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>

```
        "Friday"
    ],
    "Time": "2022-02-27T17:30:00Z"
}
```

</td></tr>
<tr><td>Monthly</td><td>A dictionary that indicates a job scheduled to run on a specific day or days every month at the same time with the parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
<tr><td>Day</td><td>The number of the day, in the month, to run the job.</td></tr>
</table>
For example, on the first of every month at 5:30 pm:

```
"Monthly": {
    "Day": 1
    "Time": "2022-02-27T17:30:00Z"
}
```

</td></tr>
<tr><td>ExactlyOnce</td><td>A dictionary that indicates a job scheduled to run at the time specified with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, exactly once at 11:45 am:

```
"ExactlyOnce": {
    "Time": "2022-02-27T11:45:00Z"
}
```

Tip: In some instances, jobs initially scheduled as *Immediate* will appear on a GET as *ExactlyOnce*.</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>MonitorSchedule</td><td>An array providing the monitoring schedule for the SSL network group. The schedule can be off (unset) or one of the supported values. Supported schedule values are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Immediate</td><td>A Boolean that indicates a job scheduled to run immediately (true) or not (false).

Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as null.</td></tr>
<tr><td>Interval</td><td>A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Minutes</td><td>An integer indicating the number of minutes between each interval.</td></tr>
</table>
For example, every hour:
<pre>"Interval": {
   "Minutes": 60
}</pre></td></tr>
<tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, daily at 11:30 pm:
<pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre></td></tr>

<tr><td>0</td><td>Unknown</td></tr>
<tr><td>1</td><td>Not Scheduled</td></tr>
<tr><td>2</td><td>Running</td></tr>
<tr><td>3</td><td>Previously Scanned</td></tr>
<tr><td>4</td><td>Scheduled</td></tr>
<tr><td>5</td><td>Disabled</td></tr>
<tr><td>6</td><td>In Quiet Hours</td></tr>
</table>
</td></tr>
<tr><td>DiscoverLastScanned</td><td>A string indicating the date and time, in UTC, of the most recent discovery job. This field is populated as soon as the job is initiated and updated when the job completes.</td></tr>
<tr><td>MonitorLastScanned</td><td>A string indicating the date and time, in UTC, of the most recent monitoring job. This field is populated as soon as the job is initiated and updated when the job completes.</td></tr>
<tr><td>SslAlertRecipients</td><td>An array of strings providing the list of recipients who will receive email messages regarding the status of SSL discovery and monitoring jobs.

Note: To improve performance in requests, data is not returned in this field for the GET /SSL/Networks method. Use the GET /SSL/Networks/{id} method to return data in this field.</td></tr>
<tr><td>AutoMonitor</td><td>A Boolean that indicates whether automatic monitoring of discovered endpoints is enabled (true) or not (false).</td></tr>
</table>

Name	Description
GetRobots	A Boolean that indicates whether orchestrators should perform a GET /robots.txt request during scans in order to behave like a webcrawler and provide an explanation of network activity (true) or not (false).
DiscoverTimeoutMs	An integer that indicates the amount of time (in milliseconds) the scan will wait (before timing out) to discover the endpoint. Shorter timeout periods will increase the overall scanning throughput, however they will also increase the chance of missing a certificate on a slow or congested network.
MonitorTimeoutMs	An integer that indicates the amount of time (in milliseconds) the scan will wait (before timing out) to receive the discovered endpoint certificate expiration details.
ExpirationAlertDays	An integer that indicates the number of days within which to begin providing warnings regarding upcoming expiration in notification email messages.
DiscoverJobParts	An integer that indicates the number of job parts that have been created for a discovery job.
MonitorJobParts	An integer that indicates the number of job parts that have been created for a monitoring job.
QuietHours	An array providing the list of scheduled quiet hour periods.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.27.6 GET SSL

The GET /SSL method is used to return a list of all discovered SSL endpoints, limited by the provided parameters. This method returns HTTP 200 OK on a success with details about the requested endpoints.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SslManagement: *Read*

Table 586: GET SSL Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns. For querying guidelines, refer to the *Keyfactor Command Reference Guide* Using the Discovery Results Search Feature on page 437 section. The query fields supported for this endpoint are: • *AgentPoolName* • *CertificateCN* • *CertificateFound* (True, False) • *Status* (6-Certificate Found, 1-Timed Out Connecting, 2-Exception Connecting, 3-Timed Out Downloading, 4- Exception Downloading, 5-Not SSL, 7-Exception in Sql, 8-Invalid or Unreachable Host, 9-Connection Refused, 10-Bad SSL Handshake, 11-Client Authentication Failed, 12-No Certificate, 13-SSL Refused, 14-Not Probed, 0-Unknown) • *IpAddress* • *IsMonitored* (True, False) • *IssuerDN* • *NetworkName* • *Port* • *ReverseDNS* • *Reviewed* (True, False) • *SelfSigned* (True, False) • *SNIName*
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *ReverseDNS*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 587: GET SSL Response Data

Name	Description
EndpointId	The Keyfactor Command reference GUID for the endpoint.
ReverseDNS	A string indicating the DNS name resolved for the endpoint based on the discovered IP address. If a host name could not be resolved, this will be the IP address.
SNIName	A string indicating the server name indication (SNI) of the endpoint, if found.
IpAddress	A string indicating the IP address of the endpoint.
Port	An integer indicating the port at which the endpoint was found.
CertificateFound	A Boolean indicating whether a certificate was found at the endpoint (true) or not (false).
AgentPoolName	A string indicating the name of the orchestrator pool that performed a scan (discovery or monitoring) on the endpoint.
NetworkName	A string indicating the name of the SSL network that performed a scan (discovery or monitoring) on the endpoint.
MonitorStatus	A Boolean indicating whether the endpoint should be monitored (true) or not (false).
CertificateCN	A string indicating the common name of the certificate that was found at the endpoint.
Reviewed	A Boolean indicating whether the endpoint has been reviewed (true) or not (false).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.27.7 GET SSL Networks

The GET /SSL/Networks method is used to retrieve one or more SSL networks from Keyfactor Command. Results can be limited to selected SSL networks using filtering, and URL parameters can be used to specify paging and the level of information detail. This method returns HTTP 200 OK on a success with details about the specified SSL networks.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SslManagement: *Read*

Table 588: GET SSL Networks Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Using the Network Scan Details Search on page 431. The query fields supported for this endpoint are: • *Name* • *Pool*
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *Name*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.This field is optional.

Table 589: GET SSL Networks Response Data

Name	Description
NetworkId	The Keyfactor Command reference GUID for the SSL network. This GUID is automatically set by Keyfactor Command.
Name	A string indicating the name for the SSL network.
AgentPoolName	A string indicating the name of the orchestrator pool assigned to the SSL network. See Orchestrator Pools Definition on page 434 in the *Keyfactor Command Reference Guide* for more information.
AgentPoolId	The Keyfactor Command reference GUID for the orchestrator pool assigned to the SSL network.
Description	A string indicating the description of the SSL network.
Enabled	A Boolean that indicates whether scanning is enabled for the SSL network (true) or not (false). If this is set to false, no new network scans will be scheduled but any current scan will finish if one was in progress when the status was changed from true to false.
DiscoverSchedule	An array providing the discovery schedule for the SSL network group. The schedule can be off (unset) or one of the supported values. Supported schedule values are:

Name	Description
Immediate	A Boolean that indicates a job scheduled to run immediately (true) or not (false). **Tip:** In some instances, jobs initially scheduled as *Immediate* will appear on a GET as *null*.
Interval	A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.

Name	Description
Minutes	An integer indicating the number of minutes between each interval.

For example, every hour:

```
"Interval": {
   "Minutes": 60
```

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td><pre>}</pre></td></tr>
<tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, daily at 11:30 pm:
<pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre></td></tr>
<tr><td>Weekly</td><td>A dictionary that indicates a job scheduled to run on a specific day or days every week at the same time with the parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
<tr><td>Days</td><td>An array of values representing the days of the week on which to run the job. These can either be entered as integers (0 for Sunday, 1 for Monday, etc.) or as days of the week (e.g. "Sunday").</td></tr>
</table>
For example, every Monday, Wednesday and Friday at 5:30 pm:
<pre>"Weekly": {
   "Days": [
      "Monday",
      "Wednesday",</pre></td></tr>
</table>
</td></tr>
</table>

<tr><td>SslAlertRecipients</td><td>An array of strings providing the list of recipients who will receive email messages regarding the status of SSL discovery and monitoring jobs.

Note: To improve performance in requests, data is not returned in this field for the GET /SSL/Networks method. Use the GET /SSL/Networks/{id} method to return data in this field.</td></tr>
<tr><td>AutoMonitor</td><td>A Boolean that indicates whether automatic monitoring of discovered endpoints is enabled (true) or not (false).</td></tr>
</table>

Name	Description
GetRobots	A Boolean that indicates whether orchestrators should perform a GET /robots.txt request during scans in order to behave like a webcrawler and provide an explanation of network activity (true) or not (false).
DiscoverTimeoutMs	An integer that indicates the amount of time (in milliseconds) the scan will wait (before timing out) to discover the endpoint. Shorter timeout periods will increase the overall scanning throughput, however they will also increase the chance of missing a certificate on a slow or congested network.
MonitorTimeoutMs	An integer that indicates the amount of time (in milliseconds) the scan will wait (before timing out) to receive the discovered endpoint certificate expiration details.
ExpirationAlertDays	An integer that indicates the number of days within which to begin providing warnings regarding upcoming expiration in notification email messages.
DiscoverJobParts	An integer that indicates the number of job parts that have been created for a discovery job.
MonitorJobParts	An integer that indicates the number of job parts that have been created for a monitoring job.
QuietHours	An array providing the list of scheduled quiet hour periods.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.27.8 POST SSL Networks

The POST /SSL/Networks method is used to create an SSL network in Keyfactor Command. This method returns HTTP 200 OK on a success with details for the new SSL network.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SslManagement: *Modify*

Table 590: POST SSL Networks Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>NetworkId</td><td>Body</td><td>The Keyfactor Command reference GUID for the SSL network. This GUID is automatically set by Keyfactor Command.</td></tr>
<tr><td>Name</td><td>Body</td><td>Required. A string indicating the name for the SSL network.</td></tr>
<tr><td>AgentPoolName</td><td>Body</td><td>Required. A string indicating the name of the orchestrator pool assigned to the SSL network. See in the Keyfactor Command Reference Guide for more information.</td></tr>
<tr><td>AgentPoolId</td><td>Body</td><td>The Keyfactor Command reference GUID for the orchestrator pool assigned to the SSL network.</td></tr>
<tr><td>Description</td><td>Body</td><td>Required. A string indicating the description of the SSL network.</td></tr>
<tr><td>Enabled</td><td>Body</td><td>A Boolean that indicates whether scanning is enabled for the SSL network (true) or not (false). If this is set to false, no new network scans will be scheduled but any current scan will finish if one was in progress when the status was changed from true to false.</td></tr>
<tr><td>DiscoverSchedule</td><td>Body</td><td>An array providing the discovery schedule for the SSL network group. The schedule can be off (unset) or one of the supported values. Supported schedule values are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Immediate</td><td>A Boolean that indicates a job scheduled to run immediately (true) or not (false).

Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as null.</td></tr>
<tr><td>Interval</td><td>A dictionary that indicates a job scheduled to run every x minutes with the specified parameter. Any interval that is selected in the UI will be converted to minutes when stored in the database.
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Minutes</td><td>An integer indicating the number of minutes between each interval.</td></tr>
</table>
For example, every hour:
<pre>"Interval": {
  "Minutes": 60</pre></td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td><pre>}</pre></td></tr>
<tr><td>Daily</td><td>A dictionary that indicates a job scheduled to run every day at the same time with the parameter:
<table><tr><th>Name</th><th>Description</th></tr><tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr></table>
For example, daily at 11:30 pm:
<pre>"Daily": {
   "Time": "2022-02-25T23:30:00Z"
}</pre></td></tr>
<tr><td>Weekly</td><td>A dictionary that indicates a job scheduled to run on a specific day or days every week at the same time with the parameters:
<table><tr><th>Name</th><th>Description</th></tr><tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr><tr><td>Days</td><td>An array of values representing the days of the week on which to run the job. These can either be entered as integers (0 for Sunday, 1 for Monday, etc.) or as days of the week (e.g. "Sunday").</td></tr></table>
For example, every Monday, Wednesday and Friday at 5:30 pm:
<pre>"Weekly": {
   "Days": [
      "Monday",</pre></td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>

<tr><td>Discov-erLastScanned</td><td>Body</td><td>A string indicating the date and time, in UTC, of the most recent discovery job. This field is populated as soon as the job is initiated and updated when the job completes. This field is for reference and is not configurable.</td></tr>
<tr><td>MonitorLastScanned</td><td>Body</td><td>A string indicating the date and time, in UTC, of the most recent monitoring job. This field is populated as soon as the job is initiated and updated when the job completes.</td></tr>
</table>

Name	In	Description
		This field is for reference and is not configurable.
SslAlertRecipients	Body	An array of strings providing the list of recipients who will receive email messages regarding the status of SSL discovery and monitoring jobs. **Note:** To improve performance in requests, data is not returned in this field for the *GET /SSL/Networks* method. Use the *GET /SSL/Networks/{id}* method to return data in this field.
AutoMonitor	Body	A Boolean that indicates whether automatic monitoring of discovered endpoints is enabled (true) or not (false).
GetRobots	Body	A Boolean that indicates whether orchestrators should perform a GET /robots.txt request during scans in order to behave like a webcrawler and provide an explanation of network activity (true) or not (false).
DiscoverTimeoutMs	Body	An integer that indicates the amount of time (in milliseconds) the scan will wait (before timing out) to discover the endpoint. Shorter timeout periods will increase the overall scanning throughput, however they will also increase the chance of missing a certificate on a slow or congested network.
MonitorTimeoutMs	Body	An integer that indicates the amount of time (in milliseconds) the scan will wait (before timing out) to receive the discovered endpoint certificate expiration details.
ExpirationAlertDays	Body	An integer that indicates the number of days within which to begin providing warnings regarding upcoming expiration in notification email messages.
DiscoverJobParts	Body	An integer that indicates the number of job parts that have been created for a discovery job. This field is for reference and is not configurable.
MonitorJobParts	Body	An integer that indicates the number of job parts that have been created for a monitoring job. This field is for reference and is not configurable.

QuietHours	Body	An array providing the list of scheduled quiet hour periods. For example:
		
		`"QuietHours": [`
		`{`
		`"StartDay": "Monday",`
		`"StartTime": "2022-11-21T14:00:08Z",`
		`"EndDay": "Tuesday",`
		`"EndTime": "2022-11-22T14:00:08Z"`
		`},`
		`{`
		`"StartDay": "Saturday",`
		`"StartTime": "2022-11-26T04:00:08Z",`
		`"EndDay": "Sunday",`

Name	In	Description

		<pre>"EndTime": "2022-11-27T16:00:08Z"
		}
		]</pre>

Table 591: POST SSL Networks Response Data

Name	Description
NetworkId	The Keyfactor Command reference GUID for the SSL network. This GUID is automatically set by Keyfactor Command.
Name	A string indicating the name for the SSL network.
AgentPoolName	A string indicating the name of the orchestrator pool assigned to the SSL network. See Orchestrator Pools Definition on page 434 in the *Keyfactor Command Reference Guide* for more information.
AgentPoolId	The Keyfactor Command reference GUID for the orchestrator pool assigned to the SSL network.
Description	A string indicating the description of the SSL network.
Enabled	A Boolean that indicates whether scanning is enabled for the SSL network (true) or not (false). If this is set to false, no new network scans will be scheduled but any current scan will finish if one was in progress when the status was changed from true to false.
DiscoverSchedule	An array providing the discovery schedule for the SSL network group.
MonitorSchedule	An array providing the monitoring schedule for the SSL network group.
DiscoverPercentComplete	An integer indicating the percentage complete for a discovery job. The percentage complete will be zero for small jobs for the entire duration of the job because this value is updated upon completion of each segment of a scan job (and small jobs generally consist of only one segment). All jobs will show 100% at completion. The counter resets when a new job begins.
MonitorPercentComplete	An integer indicating the percentage complete for a monitoring job. The percentage complete will be zero for small jobs for the entire duration of the job because this value is updated upon completion of each segment of a scan job (and small jobs generally consist of only one segment). All jobs will show 100% at completion. The counter resets when a new job begins.
DiscoverStatus	An integer indicating the status of the discovery job. Possible values are: **Value** / **Description** 0 – Unknown 1 – Not Scheduled 2 – Running

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>3</td><td>Previously Scanned</td></tr>
<tr><td>4</td><td>Scheduled</td></tr>
<tr><td>5</td><td>Disabled</td></tr>
<tr><td>6</td><td>In Quiet Hours</td></tr>
</table>
</td></tr>
<tr><td>MonitorStatus</td><td>An integer indicating the status of the monitoring job. Possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>0</td><td>Unknown</td></tr>
<tr><td>1</td><td>Not Scheduled</td></tr>
<tr><td>2</td><td>Running</td></tr>
<tr><td>3</td><td>Previously Scanned</td></tr>
<tr><td>4</td><td>Scheduled</td></tr>
<tr><td>5</td><td>Disabled</td></tr>
<tr><td>6</td><td>In Quiet Hours</td></tr>
</table>
</td></tr>
<tr><td>DiscoverLastScanned</td><td>A string indicating the date and time, in UTC, of the most recent discovery job. This field is populated as soon as the job is initiated and updated when the job completes.</td></tr>
<tr><td>MonitorLastScanned</td><td>A string indicating the date and time, in UTC, of the most recent monitoring job. This field is populated as soon as the job is initiated and updated when the job completes.</td></tr>
<tr><td>SslAlertRecipients</td><td>An array of strings providing the list of recipients who will receive email messages regarding the status of SSL discovery and monitoring jobs.

Note: To improve performance in requests, data is not returned in this field for the GET /SSL/Networks method. Use the GET /SSL/Networks/{id} method to return data in this field.</td></tr>
<tr><td>AutoMonitor</td><td>A Boolean that indicates whether automatic monitoring of discovered endpoints is enabled (true) or not (false).</td></tr>
<tr><td>GetRobots</td><td>A Boolean that indicates whether orchestrators should perform a GET /robots.txt request during scans in order to behave like a webcrawler and provide an explanation of network</td></tr>
</table>

Name	Description
	activity (true) or not (false).
DiscoverTimeoutMs	An integer that indicates the amount of time (in milliseconds) the scan will wait (before timing out) to discover the endpoint. Shorter timeout periods will increase the overall scanning throughput, however they will also increase the chance of missing a certificate on a slow or congested network.
MonitorTimeoutMs	An integer that indicates the amount of time (in milliseconds) the scan will wait (before timing out) to receive the discovered endpoint certificate expiration details.
ExpirationAlertDays	An integer that indicates the number of days within which to begin providing warnings regarding upcoming expiration in notification email messages.
DiscoverJobParts	An integer that indicates the number of job parts that have been created for a discovery job.
MonitorJobParts	An integer that indicates the number of job parts that have been created for a monitoring job.
QuietHours	An array providing the list of scheduled quiet hour periods.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.27.9 PUT SSL Networks

The PUT /SSL/Networks method is used to update an SSL network in Keyfactor Command. This method returns HTTP 200 OK on a success with details for the SSL network.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SslManagement: *Modify*

Warning: Any previously populated fields that are not submitted with their full existing data using this method will be cleared of their existing data. When using this method, you should first do a GET to retrieve all the values for the record you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing.

Table 592: PUT SSL Networks Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>NetworkId</td><td>Body</td><td>The Keyfactor Command reference GUID for the SSL network. This GUID is automatically set by Keyfactor Command.</td></tr>
<tr><td>Name</td><td>Body</td><td>Required. A string indicating the name for the SSL network.</td></tr>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>orPercentComplete</td><td></td><td>complete will be zero for small jobs for the entire duration of the job because this value is updated upon completion of each segment of a scan job (and small jobs generally consist of only one segment). All jobs will show 100% at completion. The counter resets when a new job begins. This field is for reference and is not configurable.</td></tr>
<tr><td>DiscoverStatus</td><td>Body</td><td>An integer indicating the status of the discovery job. Possible values are:<table><tr><th>Value</th><th>Description</th></tr><tr><td>0</td><td>Unknown</td></tr><tr><td>1</td><td>Not Scheduled</td></tr><tr><td>2</td><td>Running</td></tr><tr><td>3</td><td>Previously Scanned</td></tr><tr><td>4</td><td>Scheduled</td></tr><tr><td>5</td><td>Disabled</td></tr><tr><td>6</td><td>In Quiet Hours</td></tr></table></td></tr>
<tr><td>MonitorStatus</td><td>Body</td><td>An integer indicating the status of the monitoring job. Possible values are:<table><tr><th>Value</th><th>Description</th></tr><tr><td>0</td><td>Unknown</td></tr><tr><td>1</td><td>Not Scheduled</td></tr><tr><td>2</td><td>Running</td></tr><tr><td>3</td><td>Previously Scanned</td></tr><tr><td>4</td><td>Scheduled</td></tr><tr><td>5</td><td>Disabled</td></tr><tr><td>6</td><td>In Quiet Hours</td></tr></table></td></tr>
<tr><td>Discov-erLastScanned</td><td>Body</td><td>A string indicating the date and time, in UTC, of the most recent discovery job. This field is populated as soon as the job is initiated and updated when the job completes. This field is for reference and is not configurable.</td></tr>
<tr><td>MonitorLastScanned</td><td>Body</td><td>A string indicating the date and time, in UTC, of the most recent monitoring job. This field is populated as soon as the job is initiated and updated when the job completes.</td></tr>
</table>

Name	In	Description
		This field is for reference and is not configurable.
SslAlertRecipients	Body	An array of strings providing the list of recipients who will receive email messages regarding the status of SSL discovery and monitoring jobs. **Note:** To improve performance in requests, data is not returned in this field for the *GET /SSL/Networks* method. Use the *GET /SSL/Networks/{id}* method to return data in this field.
AutoMonitor	Body	A Boolean that indicates whether automatic monitoring of discovered endpoints is enabled (true) or not (false).
GetRobots	Body	A Boolean that indicates whether orchestrators should perform a GET /robots.txt request during scans in order to behave like a webcrawler and provide an explanation of network activity (true) or not (false).
DiscoverTimeoutMs	Body	An integer that indicates the amount of time (in milliseconds) the scan will wait (before timing out) to discover the endpoint. Shorter timeout periods will increase the overall scanning throughput, however they will also increase the chance of missing a certificate on a slow or congested network.
MonitorTimeoutMs	Body	An integer that indicates the amount of time (in milliseconds) the scan will wait (before timing out) to receive the discovered endpoint certificate expiration details.
ExpirationAlertDays	Body	An integer that indicates the number of days within which to begin providing warnings regarding upcoming expiration in notification email messages.
DiscoverJobParts	Body	An integer that indicates the number of job parts that have been created for a discovery job. This field is for reference and is not configurable.
MonitorJobParts	Body	An integer that indicates the number of job parts that have been created for a monitoring job. This field is for reference and is not configurable.

QuietHours	Body	An array providing the list of scheduled quiet hour periods. For example:
		
		`"QuietHours": [`
		`{`
		`"StartDay": "Monday",`
		`"StartTime": "2022-11-21T14:00:08Z",`
		`"EndDay": "Tuesday",`
		`"EndTime": "2022-11-22T14:00:08Z"`
		`},`
		`{`
		`"StartDay": "Saturday",`
		`"StartTime": "2022-11-26T04:00:08Z",`
		`"EndDay": "Sunday",`

Name	In	Description

		<pre>"EndTime": "2022-11-27T16:00:08Z"
		}
		]</pre>

Table 593: PUT SSL Networks Response Data

Name	Description
NetworkId	The Keyfactor Command reference GUID for the SSL network. This GUID is automatically set by Keyfactor Command.
Name	A string indicating the name for the SSL network.
AgentPoolName	A string indicating the name of the orchestrator pool assigned to the SSL network. See Orchestrator Pools Definition on page 434 in the *Keyfactor Command Reference Guide* for more information.
AgentPoolId	The Keyfactor Command reference GUID for the orchestrator pool assigned to the SSL network.
Description	A string indicating the description of the SSL network.
Enabled	A Boolean that indicates whether scanning is enabled for the SSL network (true) or not (false). If this is set to false, no new network scans will be scheduled but any current scan will finish if one was in progress when the status was changed from true to false.
DiscoverSchedule	An array providing the discovery schedule for the SSL network group.
MonitorSchedule	An array providing the monitoring schedule for the SSL network group.
DiscoverPercentComplete	An integer indicating the percentage complete for a discovery job. The percentage complete will be zero for small jobs for the entire duration of the job because this value is updated upon completion of each segment of a scan job (and small jobs generally consist of only one segment). All jobs will show 100% at completion. The counter resets when a new job begins.
MonitorPercentComplete	An integer indicating the percentage complete for a monitoring job. The percentage complete will be zero for small jobs for the entire duration of the job because this value is updated upon completion of each segment of a scan job (and small jobs generally consist of only one segment). All jobs will show 100% at completion. The counter resets when a new job begins.
DiscoverStatus	An integer indicating the status of the discovery job. Possible values are: **Value** / **Description** 0 – Unknown 1 – Not Scheduled 2 – Running

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>3</td><td>Previously Scanned</td></tr>
<tr><td>4</td><td>Scheduled</td></tr>
<tr><td>5</td><td>Disabled</td></tr>
<tr><td>6</td><td>In Quiet Hours</td></tr>
</table>
</td></tr>
<tr><td>MonitorStatus</td><td>An integer indicating the status of the monitoring job. Possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>0</td><td>Unknown</td></tr>
<tr><td>1</td><td>Not Scheduled</td></tr>
<tr><td>2</td><td>Running</td></tr>
<tr><td>3</td><td>Previously Scanned</td></tr>
<tr><td>4</td><td>Scheduled</td></tr>
<tr><td>5</td><td>Disabled</td></tr>
<tr><td>6</td><td>In Quiet Hours</td></tr>
</table>
</td></tr>
<tr><td>DiscoverLastScanned</td><td>A string indicating the date and time, in UTC, of the most recent discovery job. This field is populated as soon as the job is initiated and updated when the job completes.</td></tr>
<tr><td>MonitorLastScanned</td><td>A string indicating the date and time, in UTC, of the most recent monitoring job. This field is populated as soon as the job is initiated and updated when the job completes.</td></tr>
<tr><td>SslAlertRecipients</td><td>An array of strings providing the list of recipients who will receive email messages regarding the status of SSL discovery and monitoring jobs.

Note: To improve performance in requests, data is not returned in this field for the GET /SSL/Networks method. Use the GET /SSL/Networks/{id} method to return data in this field.</td></tr>
<tr><td>AutoMonitor</td><td>A Boolean that indicates whether automatic monitoring of discovered endpoints is enabled (true) or not (false).</td></tr>
<tr><td>GetRobots</td><td>A Boolean that indicates whether orchestrators should perform a GET /robots.txt request during scans in order to behave like a webcrawler and provide an explanation of network</td></tr>
</table>

Name	Description
	activity (true) or not (false).
DiscoverTimeoutMs	An integer that indicates the amount of time (in milliseconds) the scan will wait (before timing out) to discover the endpoint. Shorter timeout periods will increase the overall scanning throughput, however they will also increase the chance of missing a certificate on a slow or congested network.
MonitorTimeoutMs	An integer that indicates the amount of time (in milliseconds) the scan will wait (before timing out) to receive the discovered endpoint certificate expiration details.
ExpirationAlertDays	An integer that indicates the number of days within which to begin providing warnings regarding upcoming expiration in notification email messages.
DiscoverJobParts	An integer that indicates the number of job parts that have been created for a discovery job.
MonitorJobParts	An integer that indicates the number of job parts that have been created for a monitoring job.
QuietHours	An array providing the list of scheduled quiet hour periods.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.27.10 GET SSL Endpoints ID History

The GET /SSL/Endpoints/{id}/History method is used to return a list of history found for a given SSL endpoint. URL parameters can be used to specify paging and the level of information detail. This method returns HTTP 200 OK on a success with details for the specified endpoint.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SslManagement: *Read*

Table 594: GET SSL Endpoints {id} History Input Parameters

Name	In	Description
id	Path	**Required**. The Keyfactor Command reference GUID for the SSL endpoint for which to return history information. Use the *GET /SSL* method (see GET SSL on page 1839) to retrieve a list of all the SSL endpoints to determine the GUID of the desired endpoint.
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.

Table 595: GET SSL Endpoints {id} History Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>HistoryId</td><td>The Keyfactor Command reference GUID for the history entry.</td></tr>
<tr><td>EndpointId</td><td>The Keyfactor Command reference GUID for the endpoint with which the history is associated.</td></tr>
<tr><td>AuditId</td><td>The Keyfactor Command ID used to track progress during scan jobs.</td></tr>
<tr><td>Timestamp</td><td>The date and time the history entry was created.</td></tr>
<tr><td>Status</td><td>An integer containing the status of the scan for which the history item was created. The possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>0</td><td>Unknown</td></tr>
<tr><td>1</td><td>TimeOutConnecting</td></tr>
<tr><td>2</td><td>ExceptionConnecting</td></tr>
<tr><td>3</td><td>TimeoutDownloading</td></tr>
<tr><td>4</td><td>ExceptionDownloading</td></tr>
<tr><td>5</td><td>NotSsl</td></tr>
<tr><td>6</td><td>CertificateFound</td></tr>
<tr><td>7</td><td>ExceptionInSql</td></tr>
<tr><td>8</td><td>InvalidOrUnreachableHost</td></tr>
<tr><td>9</td><td>ConnectionRefused</td></tr>
<tr><td>10</td><td>BadSslHandshake</td></tr>
<tr><td>11</td><td>ClientAuthenticationFailed</td></tr>
<tr><td>12</td><td>NoCertificate</td></tr>
<tr><td>13</td><td>SslRefused</td></tr>
<tr><td>14</td><td>NotProbed</td></tr>
</table></td></tr>
<tr><td>JobType</td><td>An integer containing the type of scan job from which the history entry was created. The possible values are:</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>0</td><td>Unknown</td></tr>
<tr><td>1</td><td>Discovery</td></tr>
<tr><td>2</td><td>Monitoring</td></tr>
<tr><td>3</td><td>Compliance</td></tr>
</table>
</td></tr>
<tr><td>ProbeType</td><td>An integer containing the type of connection made to the endpoint for the scan from which the history entry was created. The possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>2</td><td>SSLv2</td></tr>
<tr><td>3</td><td>TLS</td></tr>
</table>
</td></tr>
<tr><td>ReverseDNS</td><td>A string indicating the DNS name of the endpoint resolved based on the discovered IP address at the time the history entry was created. If a host name could not be resolved, this will be the IP address.</td></tr>
<tr><td>HistoryCertificates</td><td>An array of certificates found at the endpoint during the scan from which the history entry was created. Information includes:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the Keyfactor Command reference ID of the certificate.</td></tr>
<tr><td>IssuedDN</td><td>A string indicating the distinguished name of the certificate.</td></tr>
<tr><td>SerialNumber</td><td>A string indicating the serial number of the certificate.</td></tr>
<tr><td>NotBefore</td><td>The date, in UTC, on which the certificate was issued by the certificate authority.</td></tr>
<tr><td>NotAfter</td><td>The date, in UTC, on which the certificate expires.</td></tr>
<tr><td>SigningAlgorithm</td><td>A string indicating the algorithm used to sign the certificate.</td></tr>
<tr><td>Thumbprint</td><td>A string indicating the thumbprint of the certificate.</td></tr>
</table>
</td></tr>
</table>

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td>IssuerDN</td><td>A string indicating the distinguished name of the issuer.</td></tr><tr><td>IssuedCN</td><td>A string indicating the common name of the certificate.</td></tr></table>

Name	Description
	Name / **Description** SubjectAltNameElements — An array containing the subject alternative name elements of the certificate. SAN data includes: **Name** / **Description** Id — An integer containing the Keyfactor Command reference ID of the SAN Element. Value — A string indicating the value of the SAN Element. Type — An integer containing the type of SAN element. The possible values are: **Value** / **Description** 0 — Other Name 1 — RFC 822 Name 2 — DNS Name 3 — X400 Address 4 — Directory Name 5 — Ediparty Name 6 — Uniform Resource Identifier 7 — IP Address 8 — Registered Id 100 — MS_NTPrincipalName 101 — MS_NTDSReplication 999 — Unknown ValueHash — A string indicating a hash of the SAN value.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.27.11 GET SSL Networks ID Parts

The GET /SSL/Networks/{id}/Parts method returns a list of scan job segments for an SSL network defined in Keyfactor Command. This method returns HTTP 200 OK on a success with the scan job segments for the specified SSL network. The results will only include more than one segment if the SSL management job was broken up into segments due to the number of endpoints it contained. The number of endpoints per segment is configurable (see the *SSL Maximum Discovery Scan Job Size* and *SSL Maximum Monitoring Scan Job Size* settings in Application Settings: Agents Tab on page 565 in the *Keyfactor Command Reference Guide*). The results from this method are of the currently in progress job or the latest completed job.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SslManagement: *Read*

Table 596: GET SSL Networks {id} Parts Input Parameters

Name	In	Description
ID	Path	**Required**. The Keyfactor Command reference GUID for the SSL network for which to retrieve scan job segments. Use the *GET /SSL/Networks* method (see GET SSL Networks on page 1841) to retrieve a list of all the SSL networks to determine the SSL network's GUID.
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Using the Network Scan Details Search on page 431.
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *Status*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 597: GET SSL Networks {id} Parts Response Data

Name	Description
ScanJobPartId	A string indicating the Keyfactor Command reference GUID for the scan job segment.
Agent	A string indicating the client machine name of the orchestrator that ran the scan job segment.
Status	An integer indicating the status of the scan job segment. Possible values are: **Value** / **Description** 1 / Not Started 2 / In Progress 3 / Complete
StartTime	The date and time at which the scan job segment started in UTC. For jobs that have not yet started, this value will be null.
EndTime	The date and time at which the scan job segment finished in UTC. For jobs that are in progress, this value will be null.
EndpointCount	An integer indicating the number of endpoints scanned for the segment.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.27.12 POST SSL NetworkRanges

The POST /SSL/NetworkRanges method is used to add network ranges to a specified SSL network. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SslManagement: *Modify*

Table 598: POST SSL Network Ranges Input Parameters

Name	In	Description
NetworkId	Body	**Required**. The Keyfactor Command reference GUID for the SSL network. Use the GET /SSL/Networks method (see GET SSL Networks on page 1841) to retrieve a list of your defined SSL networks to determine the GUID of the SSL network you want to use.
Ranges	Body	**Required**. An array of strings indicating the value(s) for the network range(s), including the IP address, network notation or host name followed by the port or ports for scanning (e.g. 192.168.12.0/24:443). For example: `"Ranges": [ "192.168.12.0/24:443", "keyexample.com:443", "222.33.44.55:443" ]`

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.27.13 PUT SSL NetworkRanges

The PUT /SSL/NetworkRanges method is used to update network ranges for a specified SSL network. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
SslManagement: *Modify*

Warning: Any previously populated fields that are not submitted with their full existing data using this method will be cleared of their existing data. When using this method, you should first do a GET to retrieve all the values for the record you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing.

Table 599: PUT SSL Network Ranges {id} Input Parameters

Name	In	Description
NetworkId	Body	**Required**. The Keyfactor Command reference GUID for the SSL network. Use the GET /SSL/Networks method (see GET SSL Networks on page 1841) to retrieve a list of your defined SSL networks to determine the GUID of the SSL network you want to use.
Ranges	Body	**Required**. An array of strings indicating the value(s) for the network range(s), including the IP address, network notation or host name followed by the port or ports for scanning (e.g. 192.168.12.0/24:443). For example: `"Ranges": [ "192.168.12.0/24:443", "keyexample.com:443", "222.33.44.55:443" ]`

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.27.14 PUT SSL Endpoints Review Status

The PUT /SSL/Endpoints/ReviewStatus method is used to update the reviewed status of the specified endpoint. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SslManagement: *Modify*

Table 600: PUT SSL Endpoints Review Status Input Parameters

Name	In	Description
Id	Body	**Required**. A string indicating the Keyfactor Command reference GUID for the endpoint to be updated. Use the *GET /SSL* method (see GET SSL on page 1839) to retrieve a list of all the SSL endpoints to determine the GUID of the desired endpoint.
Status	Body	**Required**. A Boolean indicating whether the endpoint should be marked as reviewed (true) or not (false).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.27.15 PUT SSL Endpoints Monitor Status

The PUT /SSL/Endpoints/MonitorStatus method is used to update the monitoring status of the specified endpoint. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SslManagement: *Modify*

Table 601: PUT SSL Endpoints Monitor Status Input Parameters

Name	In	Description
Id	Body	**Required**. A string indicating the Keyfactor Command reference GUID for the endpoint to be updated. Use the *GET /SSL* method (see GET SSL on page 1839) to retrieve a list of all the SSL endpoints to determine the GUID of the desired endpoint.
Status	Body	**Required**. A Boolean indicating whether monitoring should be enabled on this endpoint (true) or not (false).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.27.16 PUT SSL Endpoints Review All

The PUT /SSL/Endpoints/ReviewAll method is used to update all endpoints in the given query to set the reviewed status to true. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SslManagement: *Modify*

Table 602: PUT SSL Endpoints Review All Input Parameter

Name	In	Description
Query	Query	A string containing a query to limit the endpoints that will be marked as reviewed (e.g. field1 -eq value1 AND field2 -gt value2). If this parameter is not supplied, all endpoints will be marked as reviewed. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns. For querying guidelines, refer to the *Keyfactor Command Reference Guide*Using the Discovery Results Search Feature on page 437 section.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.27.17 PUT SSL Endpoints Monitor All

The PUT /SSL/Endpoint/MonitorAll method is used to update all endpoints in the given query to set the monitoring status to true. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SslManagement: *Modify*

Table 603: PUT SSL Endpoints Monitor All Input Parameter

Name	In	Description
Query	Query	A string containing a query to limit the endpoints that will be marked as monitored (e.g. field1 -eq value1 AND field2 -gt value2). If this parameter is not supplied, all endpoints will be marked as monitored. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns. For querying guidelines, refer to the *Keyfactor Command Reference Guide*Using the Discovery Results Search Feature on page 437 section.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.27.18 POST SSL Networks ID Scan

The POST /SSL/Networks/{id}/Scan method is used to initiate a scan job for an SSL network defined in Keyfactor Command. A scan may be manually initiated for a configured network at any time that a scan is not already running for the network or the network is not in quiet hours. When you initiate a scan, you can choose whether to run a discovery scan, a monitoring scan, or both. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SslManagement: *Modify*

Table 604: POST SSL Networks {id} Scan Input Parameters

Name	In	Description
id	Path	**Required**. A string indicating the Keyfactor Command reference GUID for the SSL network for which to initiate a manual scan. Use the *GET /SSL/Networks* method (see GET SSL Networks on page 1841) to retrieve a list of all the SSL networks to determine the SSL network's GUID.
Discovery	Body	A Boolean indicating whether to initiate a manual discovery scan (true) or not (false).
Monitoring	Body	A Boolean indicating whether to initiate a manual monitoring scan (true) or not (false).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.27.19 POST SSL Networks ID Reset

The POST /SSL/Networks/{id}/Reset method is used to reset an SSL scan. Reset deletes all scan jobs, scan job parts, logical scan jobs, and current schedules associated with the selected network. The agent job status relating to the SSL scans is set to failed and completed, and the agent is forced to register for a new session. Afterward, *Scan Now* is enabled to allow you to initiate a manual scan. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SslManagement: *Modify*

Table 605: POST SSL Networks {id} Reset Input Parameters

Name	In	Description
id	Path	**Required**. A string indicating the Keyfactor Command reference GUID for the SSL network for which to reset. Use the *GET /SSL/Networks* method (see GET SSL Networks on page 1841) to retrieve a list of all the SSL networks to determine the SSL network's GUID.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.27.20 POST SSL NetworkRanges Validate

The POST /SSL/NetworkRanges/Validate method ensures that network ranges supplied in the request are of valid structure. This endpoint returns 204 with no content upon success. Use this method to test a proposed network

range before using POST /SSL/NetworkRanges or PUT /SSL/NetworkRanges to configure it for an SSL network.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SslManagement: *Read*

Table 606: POST SSL Network Ranges Validate Input Parameters

Name	In	Description
networkRangesToVerify	Body	**Required**. An array of network ranges to validate. For example: `["10.5.4.0/24:443","192.168.12.0/16:443,22","keyexample.com:443"]`

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.27.21 DELETE SSL Networks ID

The DELETE /SSL/Networks/{id} method is used to delete an SSL network with the specified GUID from Keyfactor Command. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: SslManagement: *Modify*

Table 607: DELETE SSL Networks {id} Input Parameters

Name	In	Description
id	Path	**Required**. A string indicating the Keyfactor Command reference GUID for the SSL network to be deleted. Use the *GET /SSL/Networks* method (see GET SSL Networks on page 1841) to retrieve a list of all the SSL networks to determine the SSL network's GUID.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.28 Status

The Status component of the Keyfactor API includes methods necessary to retrieve the current list of Keyfactor API endpoints.

Table 608: Status Endpoints

Endpoint	Method	Description	Link
/Endpoints	GET	Returns a list of the Keyfactor API endpoints.	GET Status Endpoints below

3.2.28.1 GET Status Endpoints

The GET /Status/Endpoints method returns a list of all the endpoints currently available for use in the Keyfactor API. There are no input parameters for this method. This method returns HTTP 200 OK on a success with a list of all the API endpoints available in the Keyfactor API.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: None

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.29 Templates

The Templates component of the Keyfactor API includes methods necessary to programmatically edit, import and retrieve templates. Editing a template in Keyfactor Command will only apply within the software.

Table 609: Templates Endpoints

Endpoint	Method	Description	Link
/{id}	GET	Returns information about the specified template.	GET Templates ID on the next page
/Settings	GET	Returns the global template policy settings.	GET Templates Settings on page 1902
/Settings	PUT	Sets global values for template policy.	PUT Templates Settings on page 1908
/SubjectParts	GET	Returns a list of supported subject parts for template regular expressions and default subjects.	GET Templates Subject Parts on page 1921
/	GET	Returns a list of templates.	GET Templates on page 1922
/	PUT	Updates selected settings for the specified template.	PUT Templates on page 1932

Endpoint	Method	Description	Link
/Import	POST	Import templates from a specified configuration tenant into Keyfactor Command	POST Templates/Import on page 1959

3.2.29.1 GET Templates ID

The GET /Templates/{id} method is used to retrieve a specified template from Keyfactor Command. This method returns HTTP 200 OK on a success with details about the requested template.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: PkiManagement: *Read*

Table 610: GET Templates {id} Input Parameters

Name	In	Description
id	Path	**Required**. An integer specifying the ID of the template in Keyfactor Command. Use the *GET /Templates* method (see GET Templates on page 1922) to retrieve a list of all the templates to determine the template ID.

Table 611: GET Templates {id} Response Data

Name	Description
Id	An integer indicating the ID of the template in Keyfactor Command.
CommonName	A string containing the common name (short name) of the template. This name typically does not contain spaces. For a template created using a Microsoft management tool, this will be the Microsoft template name. For a template generated for an EJBCA CA, this will be built using a naming scheme of *<end entity profile name>_<certificate profile name>*.This field is populated based on information retrieved from the CA and is not configurable.
TemplateName	A string containing the name of the template. For a template created using a Microsoft management tool, this will be the Microsoft template display name. For a template generated for an EJBCA CA, this will be built using a naming scheme of *<end entity profile name> (<certificate profile name>)*. This field is populated based on information retrieved from the CA and is not configurable.
Oid	A string containing the object ID of the template in Active Directory. For Microsoft templates, this field is populated from Active Directory. For EJBCA templates, this field is generated within Keyfactor Command as an object identifier, but does not follow official OID conventions. The field is not configurable.
KeySize	A string indicating the minimum supported key size of the template as defined by the CA. The field is not configurable.
KeyType	A string indicating the key type of the template as defined by the CA. The field is not configurable.
ForestRoot	A string indicating the forest root of the template. For Microsoft templates, this field is populated from Active Directory and is not configurable. **Note:** The ForestRoot has been replaced by the ConfigurationTenant from release 10, but is retained for backwards compatibility.
ConfigurationTenant	A string indicating the configuration tenant of the template. For Microsoft templates, this field is populated from Active Directory. For EJBCA templates, this field is populated from the Keyfactor Command CA record. The field is not configurable.
FriendlyName	A string indicating the Keyfactor Command friendly name of the template. Template friendly names, if configured, appear in the dropdowns for PFX enrollment, CSR enrollment, and CSR generation in place of the template names. This can be useful in environments where the template names are long or not very human readable.
KeyRetention	A string indicating the type of key retention certificates enrolled with this template will use to store their private key in Keyfactor Command. The key retention object contains the following parameters:

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>None</td><td>The private key will not be retained.</td></tr>
<tr><td>Indefinite</td><td>The private key will be retained until it is explicitly deleted.</td></tr>
<tr><td>AfterExpiration</td><td>The private key will be retained until the specified number of days after the certificate expires (KeyRetentionDays), at which point it will be scheduled for deletion.</td></tr>
<tr><td>FromIssuance</td><td>The private key will be retained until the specified number of days after the date on which the certificate was issued (KeyRetentionDays), at which point it will be scheduled for deletion.</td></tr>
</table>
</td></tr>
<tr><td>KeyRetentionDays</td><td>An integer indicating the number of days a certificate’s private key will be retained in Keyfactor Command before being scheduled for deletion, if private key retention is enabled.</td></tr>
<tr><td>KeyArchival</td><td>A Boolean indicating whether the template has been configured with the key archival setting in Active Directory (true) or not (false). This is a reference field and is not configurable.</td></tr>
<tr><td>EnrollmentFields</td><td>An object containing custom enrollment fields. These are configured on a per-template basis to allow you to submit custom fields with CSR enrollments and PFX enrollments to supply custom request attributes to the CA during the enrollment process. This functionality offers such benefits as:
Preventing users from requesting invalid certificates, based on your specific certificate requirements per template.
Providing additional information to the CA with the CSR.
Once created on the template, these values are shown in Keyfactor Command on the PFX and CSR enrollment pages in the Additional Enrollment Fields section. The fields are mandatory during enrollment. The data will appear on the CA / Issued Certificates attribute tab for certificates enrolled with a template configured with Keyfactor Command enrollment fields.
Note: These are not metadata fields, so they are not stored in the Keyfactor Command database, but simply passed through to the CA. The CA in turn could, via a gateway or policy module, use this data to perform required actions.
The enrollment fields object contains the following parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the ID of the custom enrollment field.</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Name</td><td>A string indicating the name of the custom enrollment field. This name will appear on the enrollment pages.</td></tr>
<tr><td>Options</td><td>For multiple choice values, an array of strings containing the value choices.</td></tr>
<tr><td>DataType</td><td>An integer indicating the parameter type. The options are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>1</td><td>String: A free-form data entry field.</td></tr>
<tr><td>2</td><td>Multiple Choice: Provides a list of acceptable values for the field. The multiple choice values are provided in the Options parameter.</td></tr>
</table>
</td></tr>
</table>
</td></tr>
<tr><td>MetadataFields</td><td>An object containing template-level metadata field settings. Template-level metadata field configurations can override global metadata field configurations in these possible ways:

Configuration on the metadata field of required, optional or hidden.
The default value for the metadata field.
A regular expression defined for the field (string fields only) against which entered data will be validated along with its associated message.
For fields of data type multiple choice, the list of values that appear in multiple choice dropdowns.

Metadata field settings defined on a template apply to enrollments made with that template only. Template-level metadata field settings, if defined, take precedence over global-level metadata field settings.
The metadata fields object contains the following parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>The Keyfactor Command reference ID of the template-specific metadata setting.</td></tr>
<tr><td>DefaultValue</td><td>A string containing the default value defined for the metadata field for the specific template.</td></tr>
<tr><td>MetadataId</td><td>An integer indicating the global metadata field associated with the template-specific settings.</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Validation</td><td>A string containing the template-specific regular expression against which data entered in a string field will be validated. When a user enters information in a metadata field that does not match the specified regular expression, he or she will see the warning message specified in the Message field. For example:
<pre>^[a-zA-Z0-9'_\.\-]*@
(keyexample\.org|keyexample\.com)$</pre>This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly either "@keyexample.org" or "keyexample.com".
This field is only supported for metadata fields with data type string.</td></tr>
<tr><td>Enrollment</td><td>An integer that indicates how metadata fields should be handled on the PFX and CSR Enrollment pages. Possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>0</td><td>Optional
Users have the option to either enter a value or not enter a value in the field.</td></tr>
<tr><td>1</td><td>Required
Users are required to enter data in the field when populating metadata fields on the PFX and CSR Enrollment pages. The field is not required on the certificate details or Add Certificate page.</td></tr>
<tr><td>2</td><td>Hidden
The field is hidden and does not appear on the PFX and CSR Enrollment pages. This field still appears on the certificate details and the Add Certificate page.</td></tr>
</table></td></tr>
<tr><td>Message</td><td>A string containing a message to present when a user enters information in a metadata field that does not match the template-specific regular expression (Validation field).</td></tr>
<tr><td>Options</td><td>An array containing a comma separated list of values that should appear in the field dropdown for multiple choice fields.
This field is only supported for metadata fields with data type multiple</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>choice.</td></tr>
</table>
</td></tr>
<tr><td>AllowedEn-rollmentTypes</td><td>An integer indicating the type of enrollment allowed for the certificate template. Setting these options causes the template to appear in dropdowns in the corresponding section of the Management Portal. In the case of CSR Enrollment and PFX Enrollment, the templates only appear in dropdowns on the enrollment pages if they are available for enrollment from a CA also configured for enrollment within Keyfactor Command. See Adding or Modifying a CA Record on page 311 in the Keyfactor Command Reference Guide for more information. Possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>0</td><td>None</td></tr>
<tr><td>1</td><td>PFX Enrollment</td></tr>
<tr><td>2</td><td>CSR Enrollment</td></tr>
<tr><td>3</td><td>CSR Enrollment & PFX Enrollment</td></tr>
<tr><td>4</td><td>CSR Generation</td></tr>
<tr><td>5</td><td>CSR Generation & PFX Enrollment</td></tr>
<tr><td>6</td><td>CSR Generation & CSR Enrollment</td></tr>
<tr><td>7</td><td>CSR Enrollment, PFX Enrollment & CSR Generation</td></tr>
</table>
</td></tr>
<tr><td>TemplateRegexes</td><td>An object containing individual template-level regular expressions against which to validate the subject data. Regular expressions defined on a template apply to enrollments made with that template only. Template-level regular expressions, if defined, take precedence over system-wide regular expressions. For more information about system-wide regular expressions, see GET Templates Settings on page 1902. The template regular expression object contains the following parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>TemplateId</td><td>The Keyfactor Command reference ID of the certificate template the regular expression is associated with.</td></tr>
<tr><td>SubjectPart</td><td>A string indicating the portion of the subject the regular expression applies to (e.g. CN).</td></tr>
</table>
</td></tr>
</table>

Name	Description
	Name / **Description**
	RegEx — A string specifying the regular expression against which data entered in the indicated subject part field (e.g. CN) in the enrollment pages of the Keyfactor Command Management Portal or using an API enrollment method will be validated. Use the *GET /Templates/SubjectParts* method (see GET Templates Subject Parts on page 1921) to retrieve a list of all the supported subject parts. The following are some regular expression examples:

Subject Part	Example

CN (Common Name)	This regular expression specifies that the data entered in the field must consist of some number of characters in the first portion of the field made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly ".keyexample.com":
	`^[a-zA-Z0-9'_ \.\-]*\.keyexample\.com$`
	The default value for the Common Name regular expression is:
	`.+`
	This requires entry of at least one character in the Common Name field in the enrollment pages.

O (Organization)	This regular expression requires that the organization name entered in the field be one of "Key Example Inc", "Key Example" or "Key Example Inc.": `^(?:Key Example Inc|Key Example|Key Example, Inc\.)$` The period in the final company name (Key Example, Inc.) needs to be escaped in the regular expression with a slash ("\") but the comma does not.
OU (Organization Unit)	This regular expression requires that the organizational unit entered in the field be one of these four departments:

Name	Description
	Name / **Description**

Name

Description

Subject Part	Example
	`^(?:IT|HR|Accounting|E-Commerce)$`
L (City/Locality)	This regular expression requires that the city entered in the field be one of these five cities: `^(?:Boston|Chicago|New York|London|Dallas)$`
ST (State/Province)	This regular expression requires that the state entered in the field be one of these eight states: `^(?:Massachusetts|Illinois|New York|Ontario|Texas)$`
C (Country)	This regular expression requires that the country entered in the field be either US or CA: `^(?:US|CA)$`
E (Email)	This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly "@keyexample.com": `^[a-zA-Z0-9'_\.\-]*@keyexample\.com$`
DNS (Subject Alternative Name: DNS Name)	This regular expression specifies that the data entered in the field must consist of some number of characters in the first portion of the field made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly either ".keyexample1.com" or ".keyexample2.com": `^[a-zA-Z0-9'_\.\-]*\.(?:keyexample1\.com|keyexample2\.com)$`
IPv4 (Subject Alternative	This regular expression specifies that the data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Subject Part</th><th>Example</th></tr>
<tr><td>Name: IPv4 Address)</td><td>entered in the field must be exactly "130.101." followed by anywhere between 1 and 3 numbers followed by exactly "." followed by anywhere between 1 and 3 numbers:
<code>^130\.101\.(?:[0-9]{1,3})\.(?:[0-9]{1,3})$</code>
This regular expression specifies only that the IPv4 address is made up of 4 sets of between 1 and 3 numbers separated by periods:
<code>^(?:[0-9]{1,3}\.){3}[0-9]{1,3}$</code></td></tr>
<tr><td>IPv6 (Subject Alternative Name: IPv6 Address)</td><td>This regular expression specifies that the data entered in the field must be made up of eight sets of between one and four numbers and/or upper-case letters separated by colons:
<code>^(?:[A-F0-9]{1,4}:){7}[A-F0-9]{1,4}$</code></td></tr>
<tr><td>MAIL (Subject Alternative Name: Email)</td><td>This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly "@keyexample.com":
<code>^[a-zA-Z0-9'_\.\-]*@keyexample\.com$</code></td></tr>
<tr><td>UPN (Subject Alternative Name: User Principal Name)</td><td>This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly "@keyexample.com":
<code>^[a-zA-Z0-9'_\.\-]*@keyexample\.com$</code></td></tr>
</table>
</td></tr>
<tr><td>Error</td><td>A string specifying the error message displayed to the user when the subject part referenced in the CSR or entered for a PFX enrollment does not match</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>the given regular expression. Note that the error message already includes a leading string with the subject part (e.g. "Common Name:" or "Invalid CN provided:" depending on the interface used). Your custom message follows this.</td></tr>
</table>
</td></tr>
<tr><td>TemplateDefaults</td><td>An object containing individual template-level template default settings. Template defaults defined on a template apply to enrollments made with that template only. Template-level defaults, if defined, take precedence over system-wide template defaults. For more information about system-wide template defaults, see GET Templates Settings on page 1902. The template default object contains the following parameters:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>SubjectPart</td><td>A string indicating the portion of the subject the default applies to (e.g. L for City/Locality).
Use the GET /Templates/SubjectParts method (see GET Templates Subject Parts on page 1921) to retrieve a list of all the supported subject parts.</td></tr>
<tr><td>Value</td><td>A string containing the value to assign as the default for that subject part (e.g. Chicago).</td></tr>
</table>
</td></tr>
<tr><td>TemplatePolicy</td><td>An object containing the individual template-level template policy settings. Template policies defined on a template apply to enrollments made with that template only. Template-level policies, if defined, take precedence over system-wide template policies. For more information about system-wide template policies, see GET Templates Settings on page 1902. The template policy object contains the following parameters:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>TempalteId</td><td>The Keyfactor Command reference ID of the certificate template the policy is associated with.</td></tr>
<tr><td>RSAValidKeySizes</td><td>An object containing a comma-delimited list of integers defining the valid RSA key sizes supported for all templates used for enrollment. The supported values are:
2048
4096</td></tr>
<tr><td>ECCValidCurves</td><td>An object containing a list of strings defining the valid elliptic curve</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>algorithms for ECC templates. These may be specified using the well-known OIDs for ECC algorithms or by friendly name. Well-known OIDs include:
1.2.840.10045.3.1.7 = P-256/prime256v1/secp256r1
1.3.132.0.34 = P-384/secp384r1
1.3.132.0.35 = P-521/secp521r1
When specifying by friendly name, do not include a slash (use "P-256", not "P-256/prime256v1/secp256r1").</td></tr>
<tr><td>AllowKeyReuse</td><td>A Boolean that indicates whether private key reuse is allowed (true) or not (false). This option applies to certificate renewals. By default, this is set to true at a system-wide level.</td></tr>
<tr><td>AllowWildcards</td><td>A Boolean that indicates whether wildcards are allowed (true) or not (false). By default, this is set to true at a system-wide level.</td></tr>
<tr><td>RFCEnforcement</td><td>A Boolean that indicates whether RFC 2818 compliance enforcement is enabled (true) or not (false). When this option is set to true, certificate enrollments made through Keyfactor Command for this template must include at least one DNS SAN. In the Keyfactor Command Management Portal, this causes the CN entered in PFX enrollment to automatically be replicated as a SAN, which the user can either change or accept. For CSR enrollment, if the CSR does not have a SAN that matches the CN, one will automatically be added to the certificate if this is set. By default, this is set to false at a system-wide level.</td></tr>
<tr><td>AllowEd448</td><td>A Boolean that indicates whether Ed448 key type is allowed (true) or not (false).</td></tr>
<tr><td>AllowEd25519</td><td>A Boolean that indicates whether Ed25519 key type is allowed (true) or not (false).</td></tr>
</table>
</td></tr>
<tr><td>UseAllowedRequesters</td><td>A Boolean that indicates whether the Restrict Allowed Requesters option should be enabled (true) or not (false). The Restrict Allowed Requesters option is used to select Keyfactor Command security roles that a user must belong to in order to successfully enroll for certificates in Keyfactor Command using this template. This is typically used for EJBCA templates and Microsoft templates that are not in the local Active Directory forest, since in these cases, Keyfactor Command cannot make use of the access control model of the CA itself to determine which users can enroll for certificates; this setting replaces that functionality. This setting is similar to setting request certificates for the selected security roles at the template level on a Microsoft CA. In addition to granting permissions at the template level, you need enable the</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>Restrict Allowed Requesters option to grant permissions at the CA level. See Adding or Modifying a CA Record on page 311 in the Keyfactor Command Reference Guide for more information.</td></tr>
<tr><td>AllowedRequesters</td><td>An object containing the list of Keyfactor Command security roles—as strings—that have been granted enroll permission on the template.</td></tr>
<tr><td>DisplayName</td><td>A string indicating the Keyfactor Command display name of the template. If a template friendly name is configured, this is used as the display name. If not, the template name is used. The display name appears in the dropdowns for PFX enrollment, CSR enrollment, and CSR generation. The display name is a generated field and is not directly configurable.</td></tr>
<tr><td>RequiresApproval</td><td>A Boolean indicating whether the template has been configured with the Microsoft CA certificate manager approval option enabled (true) or not (false).

Important: Any templates that are configured on the Microsoft CA Issuance Requirements tab for CA certificate manager approval cannot be used for enrollment and associated alerting in Keyfactor Command without configuring private key retention. Any of the enabled private key retention settings (settings other than none as described for KeyRetention) will allow a template requiring manager approval to work with Keyfactor Command PFX and CSR enrollment.

 
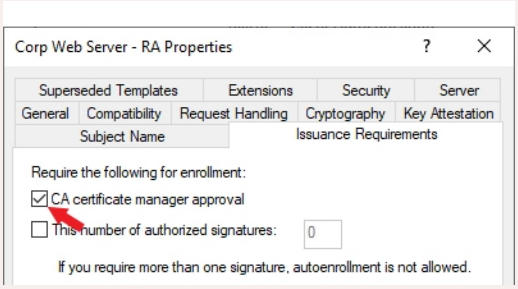

Figure 426: Microsoft Issuance Requirements on a Template for Manager Approval</td></tr>
<tr><td>KeyUsage</td><td>An integer indicating the total key usage of the certificate. Key usage is stored in Active Directory as a single value made of a combination of values. The values that make up the key usage value include:
<table>
<tr><th>Value</th><th>Function</th><th>Description</th></tr>
<tr><td>0</td><td>None</td><td>No key usage parameters.</td></tr>
<tr><td>1</td><td>Encipherment Only</td><td>The key can be used for encryption only.</td></tr>
<tr><td>2</td><td>CRL Signing</td><td>The key can be used to sign a certificate revocation list (CRL).</td></tr>
</table></td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Function</th><th>Description</th></tr>
<tr><td>4</td><td>Key Certificate Signing</td><td>The key can be used to sign certificates.</td></tr>
<tr><td>8</td><td>Key Agreement</td><td>The key can be used to determine key agreement, such as a key created using the Diffie-Hellman key agreement algorithm.</td></tr>
<tr><td>16</td><td>Data Encipherment</td><td>The key can be used for data encryption.</td></tr>
<tr><td>32</td><td>Key Encipherment</td><td>The key can be used for key encryption.</td></tr>
<tr><td>64</td><td>Nonrepudiation</td><td>The key can be used for authentication.</td></tr>
<tr><td>128</td><td>Digital Signature</td><td>The key can be used as a digital signature.</td></tr>
<tr><td>32768</td><td>Decipherment Only</td><td>The key can be used for decryption only.</td></tr>
</table>
For example, a value of 160 would represent a key usage of digital signature with key encipherment. A value of 224 would add nonrepudiation to those.
</td></tr>
<tr><td>ExtendedKeyUsages</td><td>An object containing the extended key usage information for the template. This field is populated from the CA and is not configurable. The extended key usage object contains the following parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the ID of the extended key usage in Active Directory.</td></tr>
<tr><td>Oid</td><td>A string containing the object ID of the extended key usage.</td></tr>
<tr><td>DisplayName</td><td>A string specifying the display name of the extended key usage (e.g. Server Authentication).</td></tr>
</table>
</td></tr>
<tr><td>Curve</td><td>A string indicating the OID of the elliptic curve algorithm configured for the template, for ECC templates. Well-known OIDs include:

1.2.840.10045.3.1.7 = P-256/prime256v1/secp256r1
1.3.132.0.34 = P-384/secp384r1
1.3.132.0.35 = P-521/secp521r1

</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.29.2 GET Templates Settings

The GET /Templates/Settings method is used to retrieve the global template policy settings Keyfactor Command. This method returns HTTP 200 OK on a success with details about the global template policy settings.

Tip: Template policies may also be set at an individual template level to apply to a single template (see PUT Templates on page 1932). Template policies set at the individual template level take precedence over template policies set at the global level.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: PkiManagement: *Read*

There are no input parameters for this method.

Table 612: GET Templates Settings Response Data

<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>TemplateRegexes</td><td>An object containing the system-wide template regular expression settings. These apply to all enrollments that are not otherwise overridden by individual template settings, including those that do not use a template (e.g. from a standalone CA). Regular expression details are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>SubjectPart</td><td>A string indicating the portion of the subject the regular expression applies to (e.g. CN).</td></tr>
<tr><td>RegEx</td><td>A string specifying the regular expression against which data entered in the indicated subject part field (e.g. CN) in the enrollment pages of the Keyfactor Command Management Portal or using an API enrollment method will be validated.
Use the GET /Templates/SubjectParts method (see <a>GET Templates Subject Parts on page 1921) to retrieve a list of all the supported subject parts.
The following are some regular expression examples:
<table>
<tr><th>Subject Part</th><th>Example</th></tr>
<tr><td>CN (Common Name)</td><td>This regular expression specifies that the data entered in the field must consist of some number of characters in the first portion of the field made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly ".keyexample.com":
<code>^[a-zA-Z0-9'_
\.\-]*\.keyexample\.com$</code>
The default value for the Common Name regular expression is:
<code>.+</code>
This requires entry of at least one character in the Common Name field in the enrollment pages.</td></tr>
<tr><td>O (Organization)</td><td>This regular expression requires that the organization name entered in the field be one of "Key Example Inc", "Key Example" or "Key Example Inc.":
<code>^(?:Key Example Inc|Key Example|Key Example, Inc\.)$</code>
The period in the final company name (Key Example,</td></tr>

<tr><td></td><td>ment defaults at both the system-wide and template level (see Application Settings: Enrollment Tab on page 560 in the Keyfactor Command Reference Guide) but does not apply to enrollment requests done through the Keyfactor API.</td></tr>
<tr><td>TemplatePolicy</td><td>An array containing the system-wide template policy settings. These apply to all enrollments that are not otherwise overridden by individual template settings, including those that do not use a template (e.g. from a standalone CA). Template policy details are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>RSAValidKeySizes</td><td>An object containing a comma-delimited list of integers defining the valid RSA key sizes supported for all templates used for enrollment. The supported values are:
2048
4096</td></tr>
<tr><td>ECCValidCurves</td><td>An object containing a list of strings defining the valid elliptic curve algorithms for ECC templates. These may be specified using the well-known OIDs for ECC algorithms or by friendly name. Well-known OIDs include:
1.2.840.10045.3.1.7 = P-256/prime256v1/secp256r1
1.3.132.0.34 = P-384/secp384r1
1.3.132.0.35 = P-521/secp521r1
When specifying by friendly name, do not include a slash (use "P-256", not "P-256/prime256v1/secp256r1").</td></tr>
<tr><td>AllowKeyReuse</td><td>A Boolean that indicates whether private key reuse is allowed (true) or not (false). This option allows to certificate renewals.</td></tr>
<tr><td>AllowWildcards</td><td>A Boolean that indicates whether wildcards are allowed (true) or not (false).</td></tr>
<tr><td>RFCEnforcement</td><td>A Boolean that indicates whether RFC 2818 compliance enforcement is enabled (true) or not (false). When this option is set to true, certificate enrollments made through Keyfactor Command for this template must include at least one DNS SAN. In the Keyfactor Command Management Portal, this causes the CN entered in PFX enrollment to automatically be replicated as a SAN, which the user can either change or accept. For CSR enrollment, if the CSR does not have a SAN that matches the CN, one will automatically be added to the certificate if this is set.</td></tr>
</table></td></tr>
</table>

Value	Description

	<table><tr><th>Value</th><th>Description</th></tr><tr><td>AllowEd448</td><td>A Boolean that indicates whether Ed448 key type is allowed (true) or not (false).</td></tr><tr><td>AllowEd25519</td><td>A Boolean that indicates whether Ed25519 key type is allowed (true) or not (false).</td></tr></table>
	For example:
	<pre>"TemplatePolicy": {
	  "RSAValidKeySizes": [
	  2048,
	  4096
	  ],
	  "ECCValidCurves": [
	  "1.2.840.10045.3.1.7",
	  "1.3.132.0.34"
	  "1.3.132.0.35"
	  ],
	  "AllowKeyReuse": false,
	  "AllowWildcards": true,
	  "RFCEnforcement": true,
	  "AllowEd448": false,
	  "AllowEd25519": false
	}</pre>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.29.3 PUT Templates Settings

The PUT /Templates/Settings method is used to create or update the global template policy settings in Keyfactor Command. This method returns HTTP 200 OK on a success with details about the template policy settings.

Tip: Template policies may also be set at an individual template level to apply to a single template (see PUT Templates on page 1932). Template policies set at the individual template level take precedence over template policies set at the global level.

Note: Global template settings replaced and expanded upon select enrollment-related applications settings in release 10.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: PkiManagement: *Modify*

Warning: Any previously populated fields that are not submitted with their full existing data using this method will be cleared of their existing data. When using this method, you should first do a GET to retrieve all the values for the record you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing.

Table 613: PUT Templates Settings Input Parameters

<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>TemplateRegexes</td><td>An object containing the system-wide template regular expression settings. These apply to all enrollments that are not otherwise overridden by individual template settings, including those that do not use a template (e.g. from a standalone CA). Regular expression details are:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>SubjectPart</td><td>A string indicating the portion of the subject the regular expression applies to (e.g. CN).</td></tr>
<tr><td>RegEx</td><td>A string specifying the regular expression against which data entered in the indicated subject part field (e.g. CN) in the enrollment pages of the Keyfactor Command Management Portal or using an API enrollment method will be validated.
Use the GET /Templates/SubjectParts method (see <a>GET Templates Subject Parts on page 1921) to retrieve a list of all the supported subject parts.
The following are some regular expression examples:
<table>
<tr><th>Subject Part</th><th>Example</th></tr>
<tr><td>CN (Common Name)</td><td>This regular expression specifies that the data entered in the field must consist of some number of characters in the first portion of the field made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly ".keyexample.com":
<code>^[a-zA-Z0-9'_
\.\-]*\.keyexample\.com$</code>
The default value for the Common Name regular expression is:
<code>.+</code>
This requires entry of at least one character in the Common Name field in the enrollment pages.</td></tr>
<tr><td>O (Organization)</td><td>This regular expression requires that the organization name entered in the field be one of "Key Example Inc", "Key Example" or "Key Example Inc.":
<code>^(?:Key Example Inc|Key Example|Key Example, Inc\.)$</code>
The period in the final company name (Key Example,</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Value	Description
	Name / **Description**

Subject Part	Example
	Inc.) needs to be escaped in the regular expression with a slash ("\") but the comma does not.
OU (Organization Unit)	This regular expression requires that the organizational unit entered in the field be one of these four departments: `^(?:IT|HR|Accounting|E-Commerce)$`
L (City/Locality)	This regular expression requires that the city entered in the field be one of these five cities: `^(?:Boston|Chicago|New York|London|Dallas)$`
ST (State/Province)	This regular expression requires that the state entered in the field be one of these eight states: `^(?:Massachusetts|Illinois|New York|Ontario|Texas)$`
C (Country)	This regular expression requires that the country entered in the field be either US or CA: `^(?:US|CA)$`
E (Email)	This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly "@keyexample.com": `^[a-zA-Z0-9'_\.\-]*@keyexample\.com$`
DNS (Subject Alternative Name: DNS Name)	This regular expression specifies that the data entered in the field must consist of some number of characters in the first portion of the field made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly either ".keyexample1.com" or ".keyexample2.com":

Value	Description

Name	Description

Subject Part	Example
	`^[a-zA-Z0-9'_\.\-]*\.(?:keyexample1\.com|keyexample2\.com)$`

IPv4 (Subject Alternative Name: IPv4 Address)	This regular expression specifies that the data entered in the field must be exactly "130.101." followed by anywhere between 1 and 3 numbers followed by exactly "." followed by anywhere between 1 and 3 numbers:
	`^130\.101\.(?:[0-9]{1,3})\.(?:[0-9]{1,3})$`
	This regular expression specifies only that the IPv4 address is made up of 4 sets of between 1 and 3 numbers separated by periods:
	`^(?:[0-9]{1,3}\.){3}[0-9]{1,3}$`

IPv6 (Subject Alternative Name: IPv6 Address)	This regular expression specifies that the data entered in the field must be made up of eight sets of between one and four numbers and/or uppercase letters separated by colons: `^(?:[A-F0-9]{1,4}:){7}[A-F0-9]{1,4}$`
MAIL (Subject Alternative Name: Email)	This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lower-case letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly "@keyexample.com": `^[a-zA-Z0-9'_\.\-]*@keyexample\.com$`
UPN (Subject Alternative Name: User Principal Name)	This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lower-case letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly "@keyexample.com": `^[a-zA-Z0-9'_\.\-]*@keyexample\.com$`

<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Error</td><td>A string specifying the error message displayed to the user when the subject part referenced in the CSR or entered for a PFX enrollment does not match the given regular expression. Note that the error message already includes a leading string with the subject part (e.g. "Common Name:" or "Invalid CN provided:" depending on the interface used). Your custom message follows this.</td></tr>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.29.4 GET Templates Subject Parts

The GET /Templates/SubjectParts method is used to retrieve a list of the certificate subject parts that are supported for regular expressions (TemplateRegexes) and defaults (TemplateDefaults). This method returns HTTP 200 OK on a success with the list of supported certificate subject part fields. This method has no input parameters.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
PkiManagement: *Read*

Table 615: GET Templates Subject Parts Response Data

Name	Description
SubjectPart	A string indicating the supported subject part code (e.g. L for City/Locality).
SubjectPartName	A string containing a friendly name for the subject part (e.g. City/Locality).

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.29.5 GET Templates

The GET /Templates method is used to retrieve one or more templates from Keyfactor Command. Results can be limited to selected templates using filtering, and URL parameters can be used to specify paging and the level of information detail. This method returns HTTP 200 OK on a success with details about the specified templates.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
PkiManagement: *Read*

Table 616: GET Templates Input Parameters

Name	In	Description

queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Using the Template Search Feature on page 356. The query fields supported for this endpoint are:
		• *AllowedEnrollmentType* (1-PFX Enrollment, 2-CSR Enrollment, 3-CSR Generation, `0`-None)
		• *DisplayName*
		• *FriendlyName*
		• *ForestRoot* (deprecated)
		• *ConfigurationTenant*
		• *HasPrivateKeyRetention* (True, False)
		• *IsDefaultTemplate* (True, False)
		• *KeyType* (Unknown, RSA, DSA, ECC, DH)
		• *ShortName*
		
		Tip: To filter out all the built-in Active Directory templates and display only your custom templates, use the following query:
		`IsDefaultTemplate -eq "false"`
		To filter out all templates that are not configured for either PFX Enrollment or CSR Enrollment, use the following query:
		`AllowedEnrollmentType -eq "3"`
		A value of 1 will filter out all templates except those configured for PFX Enrollment. A value of 2 will filter out all templates except those configured for CSR Enrollment.

pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *CommonName*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 617: GET Templates Response Data

Name	Description
Id	An integer indicating the ID of the template in Keyfactor Command.
CommonName	A string containing the common name (short name) of the template. This name typically does not contain spaces. For a template created using a Microsoft management tool, this will be the Microsoft template name. For a template generated for an EJBCA CA, this will be built using a naming scheme of *<end entity profile name>_<certificate profile name>*.This field is populated based on information retrieved from the CA and is not configurable.
TemplateName	A string containing the name of the template. For a template created using a Microsoft management tool, this will be the Microsoft template display name. For a template generated for an EJBCA CA, this will be built using a naming scheme of *<end entity profile name> (<certificate profile name>)*. This field is populated based on information retrieved from the CA and is not configurable.
Oid	A string containing the object ID of the template in Active Directory. For Microsoft templates, this field is populated from Active Directory. For EJBCA templates, this field is generated within Keyfactor Command as an object identifier, but does not follow official OID conventions. The field is not configurable.
KeySize	A string indicating the minimum supported key size of the template as defined by the CA. The field is not configurable.
KeyType	A string indicating the key type of the template as defined by the CA. The field is not configurable.
ForestRoot	A string indicating the forest root of the template. For Microsoft templates, this field is populated from Active Directory and is not configurable. **Note:** The ForestRoot has been replaced by the ConfigurationTenant from release 10, but is retained for backwards compatibility.
ConfigurationTenant	A string indicating the configuration tenant of the template. For Microsoft templates, this field is populated from Active Directory. For EJBCA templates, this field is populated from the Keyfactor Command CA record. The field is not configurable.
FriendlyName	A string indicating the Keyfactor Command friendly name of the template. Template friendly names, if configured, appear in the dropdowns for PFX enrollment, CSR enrollment, and CSR generation in place of the template names. This can be useful in environments where the template names are long or not very human readable.
KeyRetention	A string indicating the type of key retention certificates enrolled with this template will use to store their private key in Keyfactor Command. The key retention object contains the following parameters:

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>None</td><td>The private key will not be retained.</td></tr>
<tr><td>Indefinite</td><td>The private key will be retained until it is explicitly deleted.</td></tr>
<tr><td>AfterExpiration</td><td>The private key will be retained until the specified number of days after the certificate expires (KeyRetentionDays), at which point it will be scheduled for deletion.</td></tr>
<tr><td>FromIssuance</td><td>The private key will be retained until the specified number of days after the date on which the certificate was issued (KeyRetentionDays), at which point it will be scheduled for deletion.</td></tr>
</table>
</td></tr>
<tr><td>KeyRetentionDays</td><td>An integer indicating the number of days a certificate’s private key will be retained in Keyfactor Command before being scheduled for deletion, if private key retention is enabled.</td></tr>
<tr><td>KeyArchival</td><td>A Boolean indicating whether the template has been configured with the key archival setting in Active Directory (true) or not (false). This is a reference field and is not configurable.</td></tr>
<tr><td>EnrollmentFields</td><td>An object containing custom enrollment fields. These are configured on a per-template basis to allow you to submit custom fields with CSR enrollments and PFX enrollments to supply custom request attributes to the CA during the enrollment process. This functionality offers such benefits as:
Preventing users from requesting invalid certificates, based on your specific certificate requirements per template.
Providing additional information to the CA with the CSR.
Once created on the template, these values are shown in Keyfactor Command on the PFX and CSR enrollment pages in the Additional Enrollment Fields section. The fields are mandatory during enrollment. The data will appear on the CA / Issued Certificates attribute tab for certificates enrolled with a template configured with Keyfactor Command enrollment fields.
Note: These are not metadata fields, so they are not stored in the Keyfactor Command database, but simply passed through to the CA. The CA in turn could, via a gateway or policy module, use this data to perform required actions.
The enrollment fields object contains the following parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the ID of the custom enrollment field.</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Name</td><td>A string indicating the name of the custom enrollment field. This name will appear on the enrollment pages.</td></tr>
<tr><td>Options</td><td>For multiple choice values, an array of strings containing the value choices.</td></tr>
<tr><td>DataType</td><td>An integer indicating the parameter type. The options are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>1</td><td>String: A free-form data entry field.</td></tr>
<tr><td>2</td><td>Multiple Choice: Provides a list of acceptable values for the field. The multiple choice values are provided in the Options parameter.</td></tr>
</table>
</td></tr>
</table>
</td></tr>
<tr><td>AllowedEnrollmentTypes</td><td>An integer indicating the type of enrollment allowed for the certificate template. Setting these options causes the template to appear in dropdowns in the corresponding section of the Management Portal. In the case of CSR Enrollment and PFX Enrollment, the templates only appear in dropdowns on the enrollment pages if they are available for enrollment from a CA also configured for enrollment within Keyfactor Command. See Adding or Modifying a CA Record on page 311 in the Keyfactor Command Reference Guide for more information. Possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>0</td><td>None</td></tr>
<tr><td>1</td><td>PFX Enrollment</td></tr>
<tr><td>2</td><td>CSR Enrollment</td></tr>
<tr><td>3</td><td>CSR Enrollment & PFX Enrollment</td></tr>
<tr><td>4</td><td>CSR Generation</td></tr>
<tr><td>5</td><td>CSR Generation & PFX Enrollment</td></tr>
<tr><td>6</td><td>CSR Generation & CSR Enrollment</td></tr>
<tr><td>7</td><td>CSR Enrollment, PFX Enrollment & CSR Generation</td></tr>
</table>
</td></tr>
<tr><td>TemplateRegexes</td><td>An object containing individual template-level regular expressions against which to validate the subject data. Regular expressions defined on a template apply to enrollments made with that template only. Template-level regular expressions, if defined, take precedence over system-wide</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>regular expressions. For more information about system-wide regular expressions, see GET Templates Settings on page 1902. The template regular expression object contains the following parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>TemplateId</td><td>The Keyfactor Command reference ID of the certificate template the regular expression is associated with.</td></tr>
<tr><td>SubjectPart</td><td>A string indicating the portion of the subject the regular expression applies to (e.g. CN).</td></tr>
<tr><td>RegEx</td><td>A string specifying the regular expression against which data entered in the indicated subject part field (e.g. CN) in the enrollment pages of the Keyfactor Command Management Portal or using an API enrollment method will be validated.
Use the GET /Templates/SubjectParts method (see GET Templates Subject Parts on page 1921) to retrieve a list of all the supported subject parts.
The following are some regular expression examples:
<table>
<tr><th>Subject Part</th><th>Example</th></tr>
<tr><td>CN (Common Name)</td><td>This regular expression specifies that the data entered in the field must consist of some number of characters in the first portion of the field made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly ".keyexample.com":
<code>^[a-zA-Z0-9'_
\.\-]*\.keyexample\.com$</code>
The default value for the Common Name regular expression is:
<code>.+</code>
This requires entry of at least one character in the Common Name field in the enrollment pages.</td></tr>
<tr><td>O (Organization)</td><td>This regular expression requires that the organization name entered in the field be one of "Key Example Inc", "Key Example" or "Key Example Inc.":</td></tr>
</table></td></tr>
</table></td></tr>
</table>

Name	Description
	Name / **Description**

Name

Description

Subject Part	Example
	`^(?:Key Example Inc|Key Example|Key Example, Inc\.)$` The period in the final company name (Key Example, Inc.) needs to be escaped in the regular expression with a slash ("\") but the comma does not.
OU (Organization Unit)	This regular expression requires that the organizational unit entered in the field be one of these four departments: `^(?:IT|HR|Accounting|E-Commerce)$`
L (City/Locality)	This regular expression requires that the city entered in the field be one of these five cities: `^(?:Boston|Chicago|New York|London|Dallas)$`
ST (State/Province)	This regular expression requires that the state entered in the field be one of these eight states: `^(?:Massachusetts|Illinois|New York|Ontario|Texas)$`
C (Country)	This regular expression requires that the country entered in the field be either US or CA: `^(?:US|CA)$`
E (Email)	This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly "@keyexample.com": `^[a-zA-Z0-9'_\.\-]*@keyexample\.com$`
DNS (Subject Alternative Name: DNS	This regular expression specifies that the data entered in the field must consist of some number

Name	Description
	Name / **Description**

Subject Part	Example
Name)	of characters in the first portion of the field made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly either ".keyexample1.com" or ".keyexample2.com": `^[a-zA-Z0-9'_\.\-]*\.(?:keyexample1\.com|keyexample2\.com)$`

IPv4 (Subject Alternative Name: IPv4 Address)	This regular expression specifies that the data entered in the field must be exactly "130.101." followed by anywhere between 1 and 3 numbers followed by exactly "." followed by anywhere between 1 and 3 numbers:
	`^130\.101\.(?:[0-9]{1,3})\.(?:[0-9]{1,3})$`
	This regular expression specifies only that the IPv4 address is made up of 4 sets of between 1 and 3 numbers separated by periods:
	`^(?:[0-9]{1,3}\.){3}[0-9]{1,3}$`

IPv6 (Subject Alternative Name: IPv6 Address)	This regular expression specifies that the data entered in the field must be made up of eight sets of between one and four numbers and/or upper-case letters separated by colons: `^(?:[A-F0-9]{1,4}:){7}[A-F0-9]{1,4}$`
MAIL (Subject Alternative Name: Email)	This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly "@keyexample.com": `^[a-zA-Z0-9'_\.\-]*@keyexample\.com$`

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Subject Part</th><th>Example</th></tr>
<tr><td>UPN (Subject Alternative Name: User Principal Name)</td><td>This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly "@keyexample.com":
<code>^[a-zA-Z0-9'_
\.\-]*@keyexample\.com$</code></td></tr>
</table>
</td></tr>
<tr><td>Error</td><td>A string specifying the error message displayed to the user when the subject part referenced in the CSR or entered for a PFX enrollment does not match the given regular expression. Note that the error message already includes a leading string with the subject part (e.g. "Common Name:" or "Invalid CN provided:" depending on the interface used). Your custom message follows this.</td></tr>
</table>
</td></tr>
<tr><td>UseAllowedRequesters</td><td>A Boolean that indicates whether the Restrict Allowed Requesters option should be enabled (true) or not (false). The Restrict Allowed Requesters option is used to select Keyfactor Command security roles that a user must belong to in order to successfully enroll for certificates in Keyfactor Command using this template. This is typically used for EJBCA templates and Microsoft templates that are not in the local Active Directory forest, since in these cases, Keyfactor Command cannot make use of the access control model of the CA itself to determine which users can enroll for certificates; this setting replaces that functionality. This setting is similar to setting request certificates for the selected security roles at the template level on a Microsoft CA. In addition to granting permissions at the template level, you need enable the Restrict Allowed Requesters option to grant permissions at the CA level. See Adding or Modifying a CA Record on page 311 in the Keyfactor Command Reference Guide for more information.</td></tr>
<tr><td>AllowedRequesters</td><td>An object containing the list of Keyfactor Command security roles—as strings—that have been granted enroll permission on the template.</td></tr>
<tr><td>DisplayName</td><td>A string indicating the Keyfactor Command display name of the template. If a template friendly name is configured, this is used as the display name. If not, the template name is used. The display name appears in the dropdowns for PFX enrollment, CSR enrollment, and CSR generation. The display name is a generated field and is not directly configurable.</td></tr>
<tr><td>RequiresApproval</td><td>A Boolean indicating whether the template has been configured with the Microsoft CA certificate manager approval option enabled (true) or not (false).</td></tr>
</table>

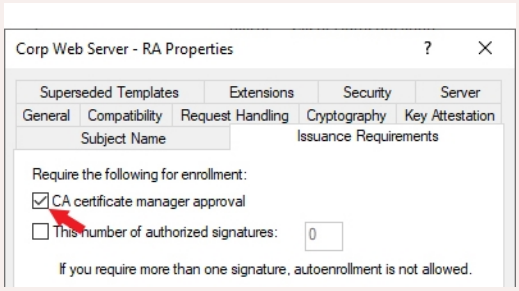
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>Important: Any templates that are configured on the Microsoft CA Issuance Requirements tab for CA certificate manager approval cannot be used for enrollment and associated alerting in Keyfactor Command without configuring private key retention. Any of the enabled private key retention settings (settings other than none as described for KeyRetention) will allow a template requiring manager approval to work with Keyfactor Command PFX and CSR enrollment.
 


Figure 427: Microsoft Issuance Requirements on a Template for Manager Approval</td></tr>
<tr><td>KeyUsage</td><td>An integer indicating the total key usage of the certificate. Key usage is stored in Active Directory as a single value made of a combination of values. The values that make up the key usage value include:
<table>
<tr><th>Value</th><th>Function</th><th>Description</th></tr>
<tr><td>0</td><td>None</td><td>No key usage parameters.</td></tr>
<tr><td>1</td><td>Encipherment Only</td><td>The key can be used for encryption only.</td></tr>
<tr><td>2</td><td>CRL Signing</td><td>The key can be used to sign a certificate revocation list (CRL).</td></tr>
<tr><td>4</td><td>Key Certificate Signing</td><td>The key can be used to sign certificates.</td></tr>
<tr><td>8</td><td>Key Agreement</td><td>The key can be used to determine key agreement, such as a key created using the Diffie-Hellman key agreement algorithm.</td></tr>
<tr><td>16</td><td>Data Encipherment</td><td>The key can be used for data encryption.</td></tr>
<tr><td>32</td><td>Key Encipherment</td><td>The key can be used for key encryption.</td></tr>
<tr><td>64</td><td>Nonrepudiation</td><td>The key can be used for authentication.</td></tr>
</table></td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Function</th><th>Description</th></tr>
<tr><td>128</td><td>Digital Signature</td><td>The key can be used as a digital signature.</td></tr>
<tr><td>32768</td><td>Decipherment Only</td><td>The key can be used for decryption only.</td></tr>
</table>
For example, a value of 160 would represent a key usage of digital signature with key encipherment. A value of 224 would add nonrepudiation to those.
</td></tr>
<tr><td>ExtendedKeyUsages</td><td>
An object containing the extended key usage information for the template. This field is populated from the CA and is not configurable. The extended key usage object contains the following parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the ID of the extended key usage in Active Directory.</td></tr>
<tr><td>Oid</td><td>A string containing the object ID of the extended key usage.</td></tr>
<tr><td>DisplayName</td><td>A string specifying the display name of the extended key usage (e.g. Server Authentication).</td></tr>
</table>
</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.29.6 PUT Templates

The PUT /Templates method is used to update selected information about a certificate template. This method returns HTTP 200 OK on a success with details about the specified template.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
PkiManagement: *Modify*

Warning: Any previously populated fields that are not submitted with their full existing data using this method will be cleared of their existing data. When using this method, you should first do a GET to retrieve all the values for the record you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing.

Table 618: PUT Templates Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>Id</td><td>Body</td><td>Required. An integer indicating the ID of the template in Keyfactor Command.</td></tr>
<tr><td>KeySize</td><td>Body</td><td>A string indicating the minimum supported key size of the template as defined by the CA. The field is not configurable.</td></tr>
<tr><td>KeyType</td><td>Body</td><td>A string indicating the key type of the template as defined by the CA. The field is not configurable.</td></tr>
<tr><td>FriendlyName</td><td>Body</td><td>A string indicating the Keyfactor Command friendly name of the template. Template friendly names, if configured, appear in the dropdowns for PFX enrollment, CSR enrollment, and CSR generation in place of the template names. This can be useful in environments where the template names are long or not very human readable.</td></tr>
<tr><td>KeyRetention</td><td>Body</td><td>A string indicating the type of key retention certificates enrolled with this template will use to store their private key in Keyfactor Command. The key retention object contains the following parameters:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>None</td><td>The private key will not be retained.</td></tr>
<tr><td>Indefinite</td><td>The private key will be retained until it is explicitly deleted.</td></tr>
<tr><td>AfterExpiration</td><td>The private key will be retained until the specified number of days after the certificate expires (KeyRetentionDays), at which point it will be scheduled for deletion.</td></tr>
<tr><td>FromIssuance</td><td>The private key will be retained until the specified number of days after the date on which the certificate was issued (KeyRetentionDays), at which point it will be scheduled for deletion.</td></tr>
</table></td></tr>
<tr><td>KeyRetentionDays</td><td>Body</td><td>An integer indicating the number of days a certificate’s private key will be retained in Keyfactor Command before being scheduled for deletion, if private key retention is enabled.</td></tr>
<tr><td>KeyArchival</td><td>Body</td><td>A Boolean indicating whether the template has been configured with the key archival setting in Active Directory (true) or not (false). This is a reference field and is not configurable.</td></tr>
<tr><td>EnrollmentFields</td><td>Body</td><td>An object containing custom enrollment fields. These are configured on a per-template basis to allow you to submit custom fields with CSR enrollments and PFX enrollments to supply custom request attributes to the CA during the enrollment process. This functionality offers such benefits as:</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>

Preventing users from requesting invalid certificates, based on your specific certificate requirements per template.
Providing additional information to the CA with the CSR.

Once created on the template, these values are shown in Keyfactor Command on the PFX and CSR enrollment pages in the Additional Enrollment Fields section. The fields are mandatory during enrollment. The data will appear on the CA / Issued Certificates attribute tab for certificates enrolled with a template configured with Keyfactor Command enrollment fields.
Note: These are not metadata fields, so they are not stored in the Keyfactor Command database, but simply passed through to the CA. The CA in turn could, via a gateway or policy module, use this data to perform required actions.
The enrollment fields object contains the following parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the ID of the custom enrollment field.</td></tr>
<tr><td>Name</td><td>A string indicating the name of the custom enrollment field. This name will appear on the enrollment pages.</td></tr>
<tr><td>Options</td><td>For multiple choice values, an array of strings containing the value choices.</td></tr>
<tr><td>DataType</td><td>An integer indicating the parameter type. The options are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>1</td><td>String: A free-form data entry field.</td></tr>
<tr><td>2</td><td>Multiple Choice: Provides a list of acceptable values for the field. The multiple choice values are provided in the Options parameter.</td></tr>
</table>
</td></tr>
</table>
For example:
<pre>
"EnrollmentFields": [
   {
      "Id": 3,
      "Name": "MyCustomField",
      "Options": ["Green","Red","Yellow","Blue"],
      "DataType": 2
   }
</pre>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td><pre>]</pre></td></tr>
<tr><td>MetadataFields</td><td>Body</td><td>An object containing template-level metadata field settings. Template-level metadata field configurations can override global metadata field configurations in these possible ways:
Configuration on the metadata field of required, optional or hidden.
The default value for the metadata field.
A regular expression defined for the field (string fields only) against which entered data will be validated along with its associated message.
For fields of data type multiple choice, the list of values that appear in multiple choice dropdowns.
Metadata field settings defined on a template apply to enrollments made with that template only. Template-level metadata field settings, if defined, take precedence over global-level metadata field settings.
The metadata fields object contains the following parameters:<table><tr><th>Name</th><th>Description</th></tr><tr><td>Id</td><td>The Keyfactor Command reference ID of the template-specific metadata setting.</td></tr><tr><td>DefaultValue</td><td>A string containing the default value defined for the metadata field for the specific template.</td></tr><tr><td>MetadataId</td><td>An integer indicating the global metadata field associated with the template-specific settings.</td></tr><tr><td>Validation</td><td>A string containing the template-specific regular expression against which data entered in a string field will be validated. When a user enters information in a metadata field that does not match the specified regular expression, he or she will see the warning message specified in the Message field. For example:<pre>^[a-zA-Z0-9'_\.\-]*@
(keyexample\.org|keyexample\.com)$</pre>This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly either "@keyexample.org" or "keyexample.com".</td></tr></table></td></tr>
</table>

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>This field is only supported for metadata fields with data type string.</td></tr>
<tr><td>Enrollment</td><td>An integer that indicates how metadata fields should be handled on the PFX and CSR Enrollment pages. Possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>0</td><td>Optional
Users have the option to either enter a value or not enter a value in the field.</td></tr>
<tr><td>1</td><td>Required
Users are required to enter data in the field when populating metadata fields on the PFX and CSR Enrollment pages. The field is not required on the certificate details or Add Certificate page.</td></tr>
<tr><td>2</td><td>Hidden
The field is hidden and does not appear on the PFX and CSR Enrollment pages. This field still appears on the certificate details and the Add Certificate page.</td></tr>
</table>
</td></tr>
<tr><td>Message</td><td>A string containing a message to present when a user enters information in a metadata field that does not match the template-specific regular expression (Validation field).</td></tr>
<tr><td>Options</td><td>An array containing a comma separated list of values that should appear in the field dropdown for multiple choice fields.
This field is only supported for metadata fields with data type multiple choice.</td></tr>
</table>
For example:
<pre>
"MetadataFields": [
  {
    "Id": 4,
    "DefaultValue": "reggie.wallace@keyexample.com",

		  "AllowWildcards": true,
		  "RFCEnforcement": true,
		  "AllowEd448": false,
		  "AllowEd25519": false
		}</pre>

UseAl-lowedRequesters	Body	A Boolean that indicates whether the Restrict Allowed Requesters option should be enabled (true) or not (false). The Restrict Allowed Requesters option is used to select Keyfactor Command security roles that a user must belong to in order to successfully enroll for certificates in Keyfactor Command using this template. This is typically used for EJBCA templates and Microsoft templates that are not in the local Active Directory forest, since in these cases, Keyfactor Command cannot make use of the access control model of the CA itself to determine which users can enroll for certificates; this setting replaces that functionality. This setting is similar to setting request certificates for the selected security roles at the template level on a Microsoft CA. In addition to granting permissions at the template level, you need enable the Restrict Allowed Requesters option to grant permissions at the CA level. See Adding or Modifying a CA Record on page 311 in the *Keyfactor Command Reference Guide* for more information.

AllowedRequesters	Body	An object containing the list of Keyfactor Command security roles—as strings—that have been granted enroll permission on the template.
		For example:
		<pre>"AllowedRequesters": [
		  "Administrator",
		  "Power Users",
		  "Revokers"
		]</pre>

RequiresApproval	Body	A Boolean indicating whether the template has been configured with the Microsoft *CA certificate manager approval* option enabled (*true*) or not (*false*). **Important:** Any templates that are configured on the Microsoft CA Issuance

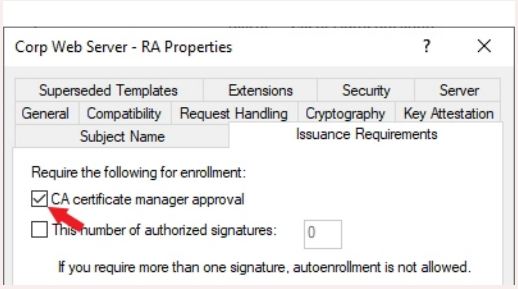
<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td></td><td></td><td>Requirements tab for CA certificate manager approval cannot be used for enrollment and associated alerting in Keyfactor Command without configuring private key retention. Any of the enabled private key retention settings (settings other than none as described for KeyRetention) will allow a template requiring manager approval to work with Keyfactor Command PFX and CSR enrollment.
 


Figure 428: Microsoft Issuance Requirements on a Template for Manager Approval</td></tr>
<tr><td>KeyUsage</td><td>Body</td><td>An integer indicating the total key usage of the certificate. Key usage is stored in Active Directory as a single value made of a combination of values. The values that make up the key usage value include:
<table>
<tr><th>Value</th><th>Function</th><th>Description</th></tr>
<tr><td>0</td><td>None</td><td>No key usage parameters.</td></tr>
<tr><td>1</td><td>Encipherment Only</td><td>The key can be used for encryption only.</td></tr>
<tr><td>2</td><td>CRL Signing</td><td>The key can be used to sign a certificate revocation list (CRL).</td></tr>
<tr><td>4</td><td>Key Certificate Signing</td><td>The key can be used to sign certificates.</td></tr>
<tr><td>8</td><td>Key Agreement</td><td>The key can be used to determine key agreement, such as a key created using the Diffie-Hellman key agreement algorithm.</td></tr>
<tr><td>16</td><td>Data Encipherment</td><td>The key can be used for data encryption.</td></tr>
<tr><td>32</td><td>Key Encipherment</td><td>The key can be used for key encryption.</td></tr>
<tr><td>64</td><td>Nonrepudiation</td><td>The key can be used for authentication.</td></tr>
<tr><td>128</td><td>Digital Signature</td><td>The key can be used as a digital signature.</td></tr>
<tr><td>32768</td><td>Decipherment Only</td><td>The key can be used for decryption only.</td></tr>
</table></td></tr>
</table>

Name	In	Description
		For example, a value of 160 would represent a key usage of *digital signature* with *key encipherment*. A value of 224 would add *nonrepudiation* to those.
Curve	Body	A string indicating the OID of the elliptic curve algorithm configured for the template, for ECC templates. Well-known OIDs include: • 1.2.840.10045.3.1.7 = P-256/prime256v1/secp256r1 • 1.3.132.0.34 = P-384/secp384r1 • 1.3.132.0.35 = P-521/secp521r1

Table 619: PUT Templates Response Body

Name	Description
Id	An integer indicating the ID of the template in Keyfactor Command.
CommonName	A string containing the common name (short name) of the template. This name typically does not contain spaces. For a template created using a Microsoft management tool, this will be the Microsoft template name. For a template generated for an EJBCA CA, this will be built using a naming scheme of *<end entity profile name>_<certificate profile name>*.This field is populated based on information retrieved from the CA and is not configurable.
TemplateName	A string containing the name of the template. For a template created using a Microsoft management tool, this will be the Microsoft template display name. For a template generated for an EJBCA CA, this will be built using a naming scheme of *<end entity profile name> (<certificate profile name>)*. This field is populated based on information retrieved from the CA and is not configurable.
Oid	A string containing the object ID of the template in Active Directory. For Microsoft templates, this field is populated from Active Directory. For EJBCA templates, this field is generated within Keyfactor Command as an object identifier, but does not follow official OID conventions. The field is not configurable.
KeySize	A string indicating the minimum supported key size of the template as defined by the CA. The field is not configurable.
KeyType	A string indicating the key type of the template as defined by the CA. The field is not configurable.
ForestRoot	A string indicating the forest root of the template. For Microsoft templates, this field is populated from Active Directory and is not configurable. **Note:** The ForestRoot has been replaced by the ConfigurationTenant from release 10, but is retained for backwards compatibility.
ConfigurationTenant	A string indicating the configuration tenant of the template. For Microsoft templates, this field is populated from Active Directory. For EJBCA templates, this field is populated from the Keyfactor Command CA record. The field is not configurable.
FriendlyName	A string indicating the Keyfactor Command friendly name of the template. Template friendly names, if configured, appear in the dropdowns for PFX enrollment, CSR enrollment, and CSR generation in place of the template names. This can be useful in environments where the template names are long or not very human readable.
KeyRetention	A string indicating the type of key retention certificates enrolled with this template will use to store their private key in Keyfactor Command. The key retention object contains the following parameters:

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>None</td><td>The private key will not be retained.</td></tr>
<tr><td>Indefinite</td><td>The private key will be retained until it is explicitly deleted.</td></tr>
<tr><td>AfterExpiration</td><td>The private key will be retained until the specified number of days after the certificate expires (KeyRetentionDays), at which point it will be scheduled for deletion.</td></tr>
<tr><td>FromIssuance</td><td>The private key will be retained until the specified number of days after the date on which the certificate was issued (KeyRetentionDays), at which point it will be scheduled for deletion.</td></tr>
</table>
</td></tr>
<tr><td>KeyRetentionDays</td><td>An integer indicating the number of days a certificate’s private key will be retained in Keyfactor Command before being scheduled for deletion, if private key retention is enabled.</td></tr>
<tr><td>KeyArchival</td><td>A Boolean indicating whether the template has been configured with the key archival setting in Active Directory (true) or not (false). This is a reference field and is not configurable.</td></tr>
<tr><td>EnrollmentFields</td><td>An object containing custom enrollment fields. These are configured on a per-template basis to allow you to submit custom fields with CSR enrollments and PFX enrollments to supply custom request attributes to the CA during the enrollment process. This functionality offers such benefits as:
Preventing users from requesting invalid certificates, based on your specific certificate requirements per template.
Providing additional information to the CA with the CSR.
Once created on the template, these values are shown in Keyfactor Command on the PFX and CSR enrollment pages in the Additional Enrollment Fields section. The fields are mandatory during enrollment. The data will appear on the CA / Issued Certificates attribute tab for certificates enrolled with a template configured with Keyfactor Command enrollment fields.
Note: These are not metadata fields, so they are not stored in the Keyfactor Command database, but simply passed through to the CA. The CA in turn could, via a gateway or policy module, use this data to perform required actions.
The enrollment fields object contains the following parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the ID of the custom enrollment field.</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Name</td><td>A string indicating the name of the custom enrollment field. This name will appear on the enrollment pages.</td></tr>
<tr><td>Options</td><td>For multiple choice values, an array of strings containing the value choices.</td></tr>
<tr><td>DataType</td><td>An integer indicating the parameter type. The options are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>1</td><td>String: A free-form data entry field.</td></tr>
<tr><td>2</td><td>Multiple Choice: Provides a list of acceptable values for the field. The multiple choice values are provided in the Options parameter.</td></tr>
</table>
</td></tr>
</table>
</td></tr>
<tr><td>MetadataFields</td><td>An object containing template-level metadata field settings. Template-level metadata field configurations can override global metadata field configurations in these possible ways:

Configuration on the metadata field of required, optional or hidden.
The default value for the metadata field.
A regular expression defined for the field (string fields only) against which entered data will be validated along with its associated message.
For fields of data type multiple choice, the list of values that appear in multiple choice dropdowns.

Metadata field settings defined on a template apply to enrollments made with that template only. Template-level metadata field settings, if defined, take precedence over global-level metadata field settings.
The metadata fields object contains the following parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>The Keyfactor Command reference ID of the template-specific metadata setting.</td></tr>
<tr><td>DefaultValue</td><td>A string containing the default value defined for the metadata field for the specific template.</td></tr>
<tr><td>MetadataId</td><td>An integer indicating the global metadata field associated with the template-specific settings.</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Validation</td><td>A string containing the template-specific regular expression against which data entered in a string field will be validated. When a user enters information in a metadata field that does not match the specified regular expression, he or she will see the warning message specified in the Message field. For example:
<code>^[a-zA-Z0-9'_\.\-]*@
(keyexample\.org|keyexample\.com)$</code>
This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly either "@keyexample.org" or "keyexample.com".
This field is only supported for metadata fields with data type string.</td></tr>
<tr><td>Enrollment</td><td>An integer that indicates how metadata fields should be handled on the PFX and CSR Enrollment pages. Possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>0</td><td>Optional
Users have the option to either enter a value or not enter a value in the field.</td></tr>
<tr><td>1</td><td>Required
Users are required to enter data in the field when populating metadata fields on the PFX and CSR Enrollment pages. The field is not required on the certificate details or Add Certificate page.</td></tr>
<tr><td>2</td><td>Hidden
The field is hidden and does not appear on the PFX and CSR Enrollment pages. This field still appears on the certificate details and the Add Certificate page.</td></tr>
</table></td></tr>
<tr><td>Message</td><td>A string containing a message to present when a user enters information in a metadata field that does not match the template-specific regular expression (Validation field).</td></tr>
<tr><td>Options</td><td>An array containing a comma separated list of values that should appear in the field dropdown for multiple choice fields.
This field is only supported for metadata fields with data type multiple</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>choice.</td></tr>
</table>
</td></tr>
<tr><td>AllowedEn-rollmentTypes</td><td>An integer indicating the type of enrollment allowed for the certificate template. Setting these options causes the template to appear in dropdowns in the corresponding section of the Management Portal. In the case of CSR Enrollment and PFX Enrollment, the templates only appear in dropdowns on the enrollment pages if they are available for enrollment from a CA also configured for enrollment within Keyfactor Command. See Adding or Modifying a CA Record on page 311 in the Keyfactor Command Reference Guide for more information. Possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>0</td><td>None</td></tr>
<tr><td>1</td><td>PFX Enrollment</td></tr>
<tr><td>2</td><td>CSR Enrollment</td></tr>
<tr><td>3</td><td>CSR Enrollment & PFX Enrollment</td></tr>
<tr><td>4</td><td>CSR Generation</td></tr>
<tr><td>5</td><td>CSR Generation & PFX Enrollment</td></tr>
<tr><td>6</td><td>CSR Generation & CSR Enrollment</td></tr>
<tr><td>7</td><td>CSR Enrollment, PFX Enrollment & CSR Generation</td></tr>
</table>
</td></tr>
<tr><td>TemplateRegexes</td><td>An object containing individual template-level regular expressions against which to validate the subject data. Regular expressions defined on a template apply to enrollments made with that template only. Template-level regular expressions, if defined, take precedence over system-wide regular expressions. For more information about system-wide regular expressions, see GET Templates Settings on page 1902. The template regular expression object contains the following parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>TemplateId</td><td>The Keyfactor Command reference ID of the certificate template the regular expression is associated with.</td></tr>
<tr><td>SubjectPart</td><td>A string indicating the portion of the subject the regular expression applies to (e.g. CN).</td></tr>
</table>
</td></tr>
</table>

Name	Description
	Name / **Description**
RegEx	A string specifying the regular expression against which data entered in the indicated subject part field (e.g. CN) in the enrollment pages of the Keyfactor Command Management Portal or using an API enrollment method will be validated. Use the *GET /Templates/SubjectParts* method (see GET Templates Subject Parts on page 1921) to retrieve a list of all the supported subject parts. The following are some regular expression examples:

Subject Part	Example

CN (Common Name)	This regular expression specifies that the data entered in the field must consist of some number of characters in the first portion of the field made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly ".keyexample.com":
	`^[a-zA-Z0-9'_ \.\-]*\.keyexample\.com$`
	The default value for the Common Name regular expression is:
	`.+`
	This requires entry of at least one character in the Common Name field in the enrollment pages.

O (Organization)	This regular expression requires that the organization name entered in the field be one of "Key Example Inc", "Key Example" or "Key Example Inc.": `^(?:Key Example Inc|Key Example|Key Example, Inc\.)$` The period in the final company name (Key Example, Inc.) needs to be escaped in the regular expression with a slash ("\") but the comma does not.
OU (Organization Unit)	This regular expression requires that the organizational unit entered in the field be one of these four departments:

Name	Description
	Name / **Description**

Subject Part	Example
	`^(?:IT|HR|Accounting|E-Commerce)$`
L (City/Locality)	This regular expression requires that the city entered in the field be one of these five cities: `^(?:Boston|Chicago|New York|London|Dallas)$`
ST (State/Province)	This regular expression requires that the state entered in the field be one of these eight states: `^(?:Massachusetts|Illinois|New York|Ontario|Texas)$`
C (Country)	This regular expression requires that the country entered in the field be either US or CA: `^(?:US|CA)$`
E (Email)	This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly "@keyexample.com": `^[a-zA-Z0-9'_\.\-]*@keyexample\.com$`
DNS (Subject Alternative Name: DNS Name)	This regular expression specifies that the data entered in the field must consist of some number of characters in the first portion of the field made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly either ".keyexample1.com" or ".keyexample2.com": `^[a-zA-Z0-9'_\.\-]*\.(?:keyexample1\.com|keyexample2\.com)$`
IPv4 (Subject Alternative	This regular expression specifies that the data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Subject Part</th><th>Example</th></tr>
<tr><td>Name: IPv4 Address)</td><td>entered in the field must be exactly "130.101." followed by anywhere between 1 and 3 numbers followed by exactly "." followed by anywhere between 1 and 3 numbers:
<code>^130\.101\.(?:[0-9]{1,3})\.(?:[0-9]{1,3})$</code>
This regular expression specifies only that the IPv4 address is made up of 4 sets of between 1 and 3 numbers separated by periods:
<code>^(?:[0-9]{1,3}\.){3}[0-9]{1,3}$</code></td></tr>
<tr><td>IPv6 (Subject Alternative Name: IPv6 Address)</td><td>This regular expression specifies that the data entered in the field must be made up of eight sets of between one and four numbers and/or upper-case letters separated by colons:
<code>^(?:[A-F0-9]{1,4}:){7}[A-F0-9]{1,4}$</code></td></tr>
<tr><td>MAIL (Subject Alternative Name: Email)</td><td>This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly "@keyexample.com":
<code>^[a-zA-Z0-9'_\.\-]*@keyexample\.com$</code></td></tr>
<tr><td>UPN (Subject Alternative Name: User Principal Name)</td><td>This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly "@keyexample.com":
<code>^[a-zA-Z0-9'_\.\-]*@keyexample\.com$</code></td></tr>
</table>
</td></tr>
<tr><td>Error</td><td>A string specifying the error message displayed to the user when the subject part referenced in the CSR or entered for a PFX enrollment does not match</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>the given regular expression. Note that the error message already includes a leading string with the subject part (e.g. "Common Name:" or "Invalid CN provided:" depending on the interface used). Your custom message follows this.</td></tr>
</table>
</td></tr>
<tr><td>TemplateDefaults</td><td>An object containing individual template-level template default settings. Template defaults defined on a template apply to enrollments made with that template only. Template-level defaults, if defined, take precedence over system-wide template defaults. For more information about system-wide template defaults, see GET Templates Settings on page 1902. The template default object contains the following parameters:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>SubjectPart</td><td>A string indicating the portion of the subject the default applies to (e.g. L for City/Locality).
Use the GET /Templates/SubjectParts method (see GET Templates Subject Parts on page 1921) to retrieve a list of all the supported subject parts.</td></tr>
<tr><td>Value</td><td>A string containing the value to assign as the default for that subject part (e.g. Chicago).</td></tr>
</table>
</td></tr>
<tr><td>TemplatePolicy</td><td>An object containing the individual template-level template policy settings. Template policies defined on a template apply to enrollments made with that template only. Template-level policies, if defined, take precedence over system-wide template policies. For more information about system-wide template policies, see GET Templates Settings on page 1902. The template policy object contains the following parameters:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>TempalteId</td><td>The Keyfactor Command reference ID of the certificate template the policy is associated with.</td></tr>
<tr><td>RSAValidKeySizes</td><td>An object containing a comma-delimited list of integers defining the valid RSA key sizes supported for all templates used for enrollment. The supported values are:
• 2048
• 4096</td></tr>
<tr><td>ECCValidCurves</td><td>An object containing a list of strings defining the valid elliptic curve</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>

</table>
For example, a value of 160 would represent a key usage of digital signature with key encipherment. A value of 224 would add nonrepudiation to those.
</td></tr>
<tr><td>ExtendedKeyUsages</td><td>An object containing the extended key usage information for the template. This field is populated from the CA and is not configurable. The extended key usage object contains the following parameters:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>An integer indicating the ID of the extended key usage in Active Directory.</td></tr>
<tr><td>Oid</td><td>A string containing the object ID of the extended key usage.</td></tr>
<tr><td>DisplayName</td><td>A string specifying the display name of the extended key usage (e.g. Server Authentication).</td></tr>
</table>
</td></tr>
<tr><td>Curve</td><td>A string indicating the OID of the elliptic curve algorithm configured for the template, for ECC templates. Well-known OIDs include:

1.2.840.10045.3.1.7 = P-256/prime256v1/secp256r1
1.3.132.0.34 = P-384/secp384r1
1.3.132.0.35 = P-521/secp521r1

</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.29.7 POST Templates/Import

The POST /Templates/Import method is used to import templates from a specified configuration tenant into Keyfactor Command. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: PkiManagement: *Modify*

Table 620: POST Templates/Import Input Parameters

Name	Description
ConfigurationTenant	A string indicating the name of the configuration tenant from which to import.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.30 Workflow Certificates

The endpoints in Keyfactor Command that are found under /Workflow/Certificates refer to the process through which certificate requests that are require manager approval at the CA level before issuance are approved or denied. These endpoints provide the ability to obtain a list of pending certificate enrollment requests, and approve or deny current requests. Endpoints are also included to view denied and external validation requests.

Note: Certificate requests that require approval at the Keyfactor Command workflow level (see Workflow Definitions on page 206 in the *Keyfactor Command Reference Guide*) are not managed with these endpoints. Instead, refer to the Workflow Definitions and Workflow Instances endpoints (see Workflow Definitions on page 1975 and Workflow Instances on page 2070).

Table 621: Workflow Certificates Endpoints

Endpoint	Method	Description	Link
/Certificates/{id}	GET	Retrieve certificate request information for a single request.	GET Workflow Certificates ID on the next page
/Certificates/Denied	GET	Retrieve a list of denied certificate request(s).	GET Workflow Certificates Denied on page 1962

Endpoint	Method	Description	Link
/Certificates/Pending	GET	Retrieve a list of outstanding pending certificate request(s).	GET Workflow Certificates Pending on page 1965
/Certificates/ExternalValidation	GET	Retrieve a list of certificate request(s) requiring external validation.	GET Workflow Certificates External Validation on page 1968
/Certificates/Approve	POST	Approve a list of pending certificate request(s).	POST Workflow Certificates Approve on page 1973
/Certificates/Deny	POST	Deny a list of pending certificate request(s).	POST Workflow Certificates Deny on page 1971

3.2.30.1 GET Workflow Certificates ID

The Workflow GET /Certificates/{id} method is used to return details for a certificate enrollment request stored within Keyfactor Command that requires manager approval at the CA level. This method returns HTTP 200 OK on a success with the specified certificate request. This method will return certificate requests with any state (e.g. Pending, Denied, External Validation).

Note: Certificate requests that require approval at the Keyfactor Command workflow level (see Workflow Definitions on page 206 in the *Keyfactor Command Reference Guide*) are not managed with this endpoint. Instead, refer to the Workflow Definitions and Workflow Instances endpoints (see Workflow Definitions on page 1975 and Workflow Instances on page 2070).

Note: Certificate requests that require approval at the CA level are supported only for Microsort CAs and select CA gateways. This feature is not supported for EJBCA CAs. Use workflow for configuring Keyfactor Command-level approvals for EJBCA CAs (see Workflow Definitions on page 206 in the *Keyfactor Command Reference Guide*).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: WorkflowManagement: *Read*

Table 622: GET Workflow Certificates {id} Input Parameters

Name	In	Description
id	Path	**Required.** An integer indicating the ID of the certificate request to retrieve. Use the *GET /Workflow/Certificates/Pending* method (see GET Workflow Certificates Pending on page 1965) to retrieve a list of all the certificate requests to determine the certificate request ID.

Table 623: GET Workflow Certificates {id} Input Parameters

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>DenialComment</td><td>A string containing the user-provided comment entered when the certificate request was denied.</td></tr>
<tr><td>KeyLength</td><td>An integer indicating the key length of the certificate request.</td></tr>
<tr><td>SANs</td><td>An object containing a comma delimited list of strings listing the subject alternative name elements of the certificate request.</td></tr>
<tr><td>CertStores</td><td>An object containing the certificate store locations to which the certificate resulting from the request will be distributed once approved. Certificate store location data includes:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>EntryName</td><td>A string indicating the alias of the certificate in the certificate store. This value will be blank for store types that use information from the issued certificate (e.g. the thumbprint) as the alias until the request is approved and a certificate issued.</td></tr>
<tr><td>ClientMachine</td><td>A string indicating the machine on which the certificate store is located.</td></tr>
<tr><td>StorePath</td><td>A string indicating the path on the machine where the certificate store is located. The format of this will vary depending on the type of store.</td></tr>
</table></td></tr>
<tr><td>Curve</td><td>A string indicating the OID of the elliptic curve algorithm configured used for the certificate request, for ECC certificate requests. Well-known OIDs include:
1.2.840.10045.3.1.7 = P-256/prime256v1/secp256r1
1.3.132.0.34 = P-384/secp384r1
1.3.132.0.35 = P-521/secp521r1</td></tr>
<tr><td>Id</td><td>An integer indicating the reference ID in Keyfactor Command for the certificate request as stored in the Keyfactor Command database. This is not the same as the request ID issued by the CA. This maps to the KeyfactorRequestId parameter for pending certificate request approve and deny actions.

Note: The reference ID for the certificate request in Keyfactor Command does not necessarily match the reference ID for the issued certificate in Keyfactor Command.</td></tr>
<tr><td>CARequestId</td><td>An integer indicating the row index of the certificate request in the certificate authority.</td></tr>
<tr><td>CommonName</td><td>A string indicating the common name of the requested certificate.</td></tr>
</table>

Name	Description
DistinguishedName	A string indicating the distinguished name of the requested certificate.
SubmissionDate	The date and time at which the certificate request was received, as an ISO-8601 formatted UTC timestamp.
CertificateAuthority	A string indicating the name of the certificate authority from which the certificate was requested in hostname\logical name format. For example: `corpca01.keyexample.com\\CorpIssuingCA1`
Template	A string indicating the name of the template used for the certificate request.
Requester	A string containing the name of the identity that requested the certificate.
State	An integer indicating the request state of the certificate. The possible values are: • Unknown (0) • Active (1) • Revoked (2) • Denied (3) • Failed (4) • Pending (5) • Certificate Authority (6) • Parent Certificate Authority (7) • External Validation (8)
StateString	A string indicating the request state of the certificate (e.g. Pending).
Metadata	An array containing the metadata fields populated for the certificate request.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.30.2 GET Workflow Certificates Denied

The GET /Workflow/Certificates/Denied method is used to return a list of denied certificate enrollment requests stored within Keyfactor Command for requests that required manager approval at the CA level. Results can be limited to selected requests using filtering, and URL parameters can be used to specify paging and the level of information detail. This method returns HTTP 200 OK on a success with the specified denied certificate requests.

Note: Certificate requests that require approval at the Keyfactor Command workflow level (see Workflow Definitions on page 206 in the *Keyfactor Command Reference Guide*) are not managed with this endpoint.

Instead, refer to the Workflow Definitions and Workflow Instances endpoints (see Workflow Definitions on page 1975 and Workflow Instances on page 2070).

Note: Certificate requests that require approval at the CA level are supported only for Microsort CAs and select CA gateways. This feature is not supported for EJBCA CAs. Use workflow for configuring Keyfactor Command-level approvals for EJBCA CAs (see Workflow Definitions on page 206 in the *Keyfactor Command Reference Guide*).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
WorkflowManagement: *Read*

Table 624: GET Workflow Certificates Denied Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Certificate Search Page on page 31. The query fields supported for this endpoint are: • *CAHostname* • *CALogical* • *CommonName* • *Requester* • *RequestType* (3 Denied, 5-Pending, 8-External Validation) This method only returns records of type (State) 3. • *SubmissionDate* • *Template*  **Tip:** For example, for recent denied requests from requester key_service: SubmissionDate -ge "2022-09-01T00:00:00Z" AND Requester -eq "KEYEXAMPLE\key_service"
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *CommonName*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 625: GET Workflow Certificates Denied Response Data

Name	Description
Id	An integer indicating the reference ID in Keyfactor Command for the certificate request as stored in the Keyfactor Command database. This is not the same as the request ID issued by the CA. This maps to the KeyfactorRequestId parameter for pending certificate request approve and deny actions.
CARequestId	An integer indicating the row index of the certificate request in the certificate authority.
CommonName	A string indicating the common name of the requested certificate.
DistinguishedName	A string indicating the distinguished name of the requested certificate.
SubmissionDate	The date and time at which the certificate request was received, as an ISO-8601 formatted UTC timestamp.
CertificateAuthority	A string indicating the name of the certificate authority from which the certificate was requested in hostname\logical name format. For example: `corpca01.keyexample.com\\CorpIssuingCA1`
Template	A string indicating the name of the template used for the certificate request.
Requester	A string containing the name of the identity that requested the certificate.
State	An integer indicating the request state of the certificate. **Note:** This method returns only requests with state 3 (denied).
StateString	A string indicating the request state of the certificate (e.g. Pending). **Note:** This method returns only requests with a Denied state.
Metadata	An array containing the metadata fields populated for the certificate request.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.30.3 GET Workflow Certificates Pending

The GET /Workflow/Certificates/Pending method is used to return a list of pending certificate enrollment requests stored within Keyfactor Command for requests that require manager approval at the CA level. Results can be limited to selected requests using filtering, and URL parameters can be used to specify paging and the level of information detail. This method returns HTTP 200 OK on a success with the specified pending certificate requests.

Note: Certificate requests that require approval at the Keyfactor Command workflow level (see Workflow Definitions on page 206 in the *Keyfactor Command Reference Guide*) are not managed with this endpoint. Instead, refer to the Workflow Definitions and Workflow Instances endpoints (see Workflow Definitions on page 1975 and Workflow Instances on page 2070).

Note: Certificate requests that require approval at the CA level are supported only for Microsort CAs and select CA gateways. This feature is not supported for EJBCA CAs. Use workflow for configuring Keyfactor Command-level approvals for EJBCA CAs (see Workflow Definitions on page 206 in the *Keyfactor Command Reference Guide*).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: WorkflowManagement: *Read*

Table 626: GET Workflow Certificates Pending Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Certificate Search Page on page 31. The query fields supported for this endpoint are: • *CAHostname* • *CALogical* • *CommonName* • *Requester* • *RequestType* (3 Denied, 5-Pending, 8-External Validation) This method only returns records of type (State) 5. • *SubmissionDate* • *Template* **Tip:** For example, for recent pending requests from requester key_service: SubmissionDate -ge "2022-09-01T00:00:00Z" AND Requester -eq "KEYEXAMPLE\key_service"
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *CommonName*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 627: GET Workflow Certificates Pending Response Data

Name	Description
Id	An integer indicating the reference ID in Keyfactor Command for the certificate request as stored in the Keyfactor Command database. This is not the same as the request ID issued by the CA. This maps to the KeyfactorRequestId parameter for pending certificate request approve and deny actions.
CARequestId	An integer indicating the row index of the certificate request in the certificate authority.
CommonName	A string indicating the common name of the requested certificate.
DistinguishedName	A string indicating the distinguished name of the requested certificate.
SubmissionDate	The date and time at which the certificate request was received, as an ISO-8601 formatted UTC timestamp.
CertificateAuthority	A string indicating the name of the certificate authority from which the certificate was requested in hostname\logical name format. For example: `corpca01.keyexample.com\\CorpIssuingCA1`
Template	A string indicating the name of the template used for the certificate request.
Requester	A string containing the name of the identity that requested the certificate.
State	An integer indicating the request state of the certificate. **Note:** This method returns only requests with state 5 (pending).
StateString	A string indicating the request state of the certificate (e.g. Pending). **Note:** This method returns only requests with a Pending state.
Metadata	An array containing the metadata fields populated for the certificate request.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.30.4 GET Workflow Certificates External Validation

The GET /Workflow/Certificates/ExternalValidation method is used to return a list of certificate enrollment requests requiring external validation (at the public CA level) stored within Keyfactor Command. Results can be limited to selected requests using filtering, and URL parameters can be used to specify paging and the level of

information detail. This method returns HTTP 200 OK on a success with the specified certificate requests requiring external validation.

Note: Certificate requests that require approval at the Keyfactor Command workflow level (see Workflow Definitions on page 206 in the *Keyfactor Command Reference Guide*) are not managed with this endpoint. Instead, refer to the Workflow Definitions and Workflow Instances endpoints (see Workflow Definitions on page 1975 and Workflow Instances on page 2070).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
WorkflowManagement: *Read*

Table 628: GET Workflow Certificates External Validation Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Certificate Search Page on page 31. The query fields supported for this endpoint are: • *CAHostname* • *CALogical* • *CommonName* • *Requester* • *RequestType* (3 Denied, 5-Pending, 8-External Validation) This method only returns records of type (State) 8. • *SubmissionDate* • *Template* **Tip:** For example, for recent external validation requests from requester key_service: SubmissionDate -ge "2022-09-01T00:00:00Z" AND Requester -eq "KEYEXAMPLE\key_service"
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *CommonName*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 629: GET Workflow Certificates External Validation Response Data

Name	Description
Id	An integer indicating the reference ID in Keyfactor Command for the certificate request as stored in the Keyfactor Command database. This is not the same as the request ID issued by the CA. This maps to the KeyfactorRequestId parameter for pending certificate request approve and deny actions.
CARequestId	An integer indicating the row index of the certificate request in the certificate authority.
CommonName	A string indicating the common name of the requested certificate.
DistinguishedName	A string indicating the distinguished name of the requested certificate.
SubmissionDate	The date and time at which the certificate request was received, as an ISO-8601 formatted UTC timestamp.
CertificateAuthority	A string indicating the name of the certificate authority from which the certificate was requested in hostname\logical name format. For example: `corpca01.keyexample.com\\CorpIssuingCA1`
Template	A string indicating the name of the template used for the certificate request.
Requester	A string containing the name of the identity that requested the certificate.
State	An integer indicating the request state of the certificate. **Note:** This method returns only requests with state 8 (external validation).
StateString	A string indicating the request state of the certificate (e.g. Pending). **Note:** This method returns only requests with an External Validation state.
Metadata	An array containing the metadata fields populated for the certificate request.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.30.5 POST Workflow Certificates Deny

The POST /Workflow/Certificates/Deny method will attempt to deny the provided pending certificate enrollment request(s) that require manager approval at the CA level. The certificate request IDs should be supplied in the request body as a JSON array of integers. This method returns HTTP 200 OK on a success with details about successful, failed and denied denial requests.

Note: Certificate requests that require approval at the Keyfactor Command workflow level (see Workflow Definitions on page 206 in the *Keyfactor Command Reference Guide*) are not managed with this endpoint. Instead, refer to the Workflow Definitions and Workflow Instances endpoints (see Workflow Definitions on page 1975 and Workflow Instances on page 2070).

Note: Certificate requests that require approval at the CA level are supported only for Microsort CAs and select CA gateways. This feature is not supported for EJBCA CAs. Use workflow for configuring Keyfactor Command-level approvals for EJBCA CAs (see Workflow Definitions on page 206 in the *Keyfactor Command Reference Guide*).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: WorkflowManagement: *Participate*

Table 630: POST Workflow Certificates Deny Input Parameters

Name	In	Description
CertificateRequestIds	Body	**Required**. An array of Keyfactor Command certificate request IDs for certificate requests that should be denied in the form: `[23,45,12]` Use the *GET /Workflow/Certificates/Pending* method (see GET Workflow Certificates Pending on page 1965) to retrieve a list of all the pending certificate requests to determine the certificate request's IDs.
Comment	Body	A string providing a comment regarding the denial. This comment can be delivered to the requester or other interested party using a denied request alert.

Table 631: POST Workflow Certificates Deny Response Data

Name	Description
Successes	An array of the successful denial response details. Response details contain the following information: **Name** / **Description** CAHost — Host name of the certificate authority to which the certificate enrollment request was submitted. CALogicalName — Logical name of the certificate authority to which the certificate enrollment request was submitted. CARequestId — The row index of the certificate request in the certificate authority. KeyfactorRequestId — An integer indicating the Keyfactor Command reference ID for the requested certificate as stored in the Keyfactor Command database. This is not the same as the request ID issued by the CA. This maps to the Id response parameter for the *GET /Workflow/Certificate/Pending* method. Comment — A comment about the denial. For example, for a deny that succeeds, the comment will be "Successful". Denies that fail or are denies will have alternate comments (see below).
Failures	An array of the failed approval response details containing the information noted above for successes. Failures of this type are generally exceptions.
Denials	An array of the denial requests that were denied containing the information noted above for successes. Denials are usually the result of insufficient user permissions required to perform the deny.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.30.6 POST Workflow Certificates Approve

The POST /Workflow/Certificates/Approve method will attempt to approve the provided pending certificate enrollment request(s) that require manager approval at the CA level. The certificate request IDs should be supplied in the request body as a JSON array of integers. This method returns HTTP 200 OK on a success with details about successful, failed and denied approval requests.

Note: Certificate requests that require approval at the Keyfactor Command workflow level (see Workflow Definitions on page 206 in the *Keyfactor Command Reference Guide*) are not managed with this endpoint. Instead, refer to the Workflow Definitions and Workflow Instances endpoints (see Workflow Definitions on page 1975 and Workflow Instances on page 2070).

Note: Certificate requests that require approval at the CA level are supported only for Microsort CAs and select CA gateways. This feature is not supported for EJBCA CAs. Use workflow for configuring Keyfactor Command-level approvals for EJBCA CAs (see Workflow Definitions on page 206 in the *Keyfactor Command Reference Guide*).

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
WorkflowManagement: *Participate*

Table 632: POST Workflow Certificates Approve Input Parameters

Name	In	Description
requestIds	Body	**Required**. An array of Keyfactor Command certificate request IDs for certificate requests that should be approved in the form (without parameter name): `[23,45,12]` Use the *GET /Workflow/Certificates/Pending* method (see GET Workflow Certificates Pending on page 1965) to retrieve a list of all the certificate requests to determine the certificate request's IDs.

Table 633: POST Workflow Certificates Approve Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Successes</td><td>An array of the successful approval response details. Response details contain the following information:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>CAHost</td><td>Host name of the certificate authority to which the certificate enrollment request was submitted.</td></tr>
<tr><td>CALogicalName</td><td>Logical name of the certificate authority to which the certificate enrollment request was submitted.</td></tr>
<tr><td>CARequestId</td><td>The row index of the certificate request in the certificate authority.</td></tr>
<tr><td>KeyfactorRequestId</td><td>An integer indicating the Keyfactor Command reference ID for the requested certificate as stored in the Keyfactor Command database. This is not the same as the request ID issued by the CA. This maps to the Id response parameter for the GET /Workflow/Certificate/Pending method.</td></tr>
<tr><td>Comment</td><td>A reason or description about why the request denials succeeded, failed or were denied.</td></tr>
</table></td></tr>
<tr><td>Failures</td><td>An array of the failed approval response details containing the information noted above for successes. Failures of this type are generally exceptions.</td></tr>
<tr><td>Denials</td><td>An array of the approval requests that were denied containing the information noted above for successes. Denials are usually the result of insufficient user permissions required to perform the approval.</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon () at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.31 Workflow Definitions

The Workflow Definitions component of the Keyfactor API includes methods necessary to programmatically create, edit, retrieve, and test workflow definitions. There are two types of workflow definition:

- Global

  The global workflow definitions are built into the product and cannot be deleted, though they can be modified to add workflow steps, if desired. Global workflow definitions do not have a specific associated *key*—in the case of the currently available workflows, this is a *certificate template*—and apply to all requests of the workflow's type (e.g. enrollment) that are not otherwise handled by a custom workflow specifying a key.

- Custom

Custom workflow definitions are any additional workflow definitions you define beyond the built-in ones. Custom workflows are associated with a specific *key* (certificate template) and each workflow only applies to requests made using that key.

All enrollment, certificate renewal, and revocation requests go through workflow even if you haven't created any workflow steps or added any custom workflow definitions. In the absence of customization, the global workflow definitions are used.

For more information about workflows, see Workflow Definitions on page 206 in the *Keyfactor Command Reference Guide*.

Table 634: Workflow Definitions Endpoints

Endpoint	Method	Description	Link
/Steps/{extensionName}	GET	Returns information about the structure of the workflow definition step with the specified name.	GET Workflow Definitions Steps Extension Name on the next page
/{definitionId}	DELETE	Deletes the workflow definition with the specified GUID.	DELETE Workflow Definitions Definition ID on page 1979
/{definitionId}	GET	Returns details of the workflow definition, including steps, for the workflow with the specified GUID.	GET Workflow Definitions Definition ID on page 1979
/{definitionId}	PUT	Updates the name and description of the workflow definition with the specified GUID.	PUT Workflow Definitions Definition ID on page 1996
/	GET	Returns a list of workflow definitions, without steps.	GET Workflow Definitions on page 2013
/	POST	Creates a new workflow definition, without steps.	POST Workflow Definitions on page 2015
/Steps	GET	Returns information about the structure of the workflow definitions.	GET Workflow Definitions Steps on page 2032
/Types	GET	Returns a list of the defined workflow definition types.	GET Workflow Definitions Types on page 2034
/{definitionId}/Steps	PUT	Updates the workflow definition with the specified GUID to add new steps or modify existing steps.	PUT Workflow Definitions Definition ID Steps on page 2035
/{definitionId}/Publish	POST	Publishes the workflow definition with the specified GUID to activate it for use.	POST Workflow Definitions Definition ID Publish on page 2054

3.2.31.1 GET Workflow Definitions Steps Extension Name

The GET /Workflow/Definitions/Steps/{extensionName} method is used to retrieve the workflow definition step structure for the step with the specified extensionName. Its primary use case is to populate the UI dialog in which step information is configured. When you are developing a custom workflow step, it can be used to confirm that the workflow step will display correctly in the UI. This method returns HTTP 200 OK on a success with information about the structure of the workflow definition step.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: WorkflowDefinitions: *Read*

Table 635: GET Workflow Definitions Steps {extensionName} Input Parameters

Name	In	Description
extensionName	Path	**Required**. A string indicating the *extensionName* of the workflow definition step to retrieve. Use the *GET /Workflow/Definitions/Steps* method (see GET Workflow Definitions Steps on page 2032) to retrieve a list of all the workflow definition steps to determine the extensionName.

Table 636: GET Workflow Definitions Steps {extensionName} Response Data

Name	Description
DisplayName	A string indicating the display name of the workflow definition step.
ExtensionName	A string indicating the extension name of the workflow definition step. The built-in extension names are: • **Email**—Send an email message. This is a separate email message from those typically sent as part of a *RequireApproval* step. • **EnrollStep**—Enroll for a certificate through Keyfactor Command. • **NOOPStep**—An entry or exit step in which no operation occurs. Steps of this type indicate the start and end of the workflow. • **PowerShell**—Run a PowerShell script. The script contents are embedded within the step. It does not call out to an external file. • **RequireApproval**—Require approval for a workflow step before the step can be completed. This step includes logic to gather the correct number of approvals from the users with the correct security roles and to send an email message indicating whether the step was approved or denied. This step does not include logic to send an email initiating the approval process. Use an *Email* type for this. **Important:** Workflows are not supported with CA delegation when they contain steps that require approval. For more information, see the CA configuration Authorization Methods Tab on page 322 in the *Keyfactor Command Reference Guide*. • **RestRequest**—Run a REST request. The REST request contents are embedded within the step. It does not call out to an external file. • **RevokeStep**—Revoke a certificate through Keyfactor Command.
Outputs	An object containing the outputs for the workflow definition step. For the built-in steps, the only output is an indicator for the next step in the workflow.
ConfigurationParametersDefinition	An object containing the configuration parameters for the workflow definition step. These will vary depending on the step.
SignalsDefinition	An object containing the signals defined for the workflow definition step. These will vary depending on the step.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.31.2 DELETE Workflow Definitions Definition ID

The DELETE /Workflow/Definitions/{definitionid} method is used to delete the workflow definition with the specified GUID. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: WorkflowDefinitions: *Modify*

Note: The built-in global workflow definitions (*Global Revocation Workflow* and *Global Enrollment Workflow*) cannot be deleted. A workflow definition cannot be deleted if there is an active or suspended workflow instance for the workflow definition.

Table 637: DELETE Workflow Definitions {definitionid} Input Parameters

Name	In	Description
definitionId	Path	**Required**. A string indicating the Keyfactor Command reference GUID of the workflow definition to delete. Use the *GET /Workflow/Definitions* method (see GET Workflow Definitions on page 2013) to retrieve a list of all the workflow definitions to determine the GUID.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.31.3 GET Workflow Definitions Definition ID

The GET /Workflow/Definitions/{definitionid} method is used to retrieve the workflow definition with the specified GUID. This method returns HTTP 200 OK on a success with details about the specified workflow definition.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: WorkflowDefinitions: *Read*

Table 638: GET Workflow Definitions {definitionid} Input Parameters

Name	In	Description
definitionId	Path	**Required**. A string indicating the Keyfactor Command reference GUID of the workflow definition to retrieve. Use the *GET /Workflow/Definitions* method (see GET Workflow Definitions on page 2013) to retrieve a list of all the workflow definitions to determine the GUID.
definitionVersion	Query	An integer indicating which version of the workflow definition to return. The default is to return the most recent version (which may not necessarily be the published version).
exportable	Query	A Boolean indicating whether any security RoleIds (see Security Roles on page 1624) in the workflow definition should be removed from the response (true) or not (false). A value of *true* allows for the workflow definition to be exported without role-specific data. The default is *false*.

Table 639: GET Workflow Definitions {definitionsid} Response Data

Name	Description
Id	A string indicating the Keyfactor Command reference GUID of the workflow definition.
DisplayName	A string indicating the display name defined for the workflow definition.
Description	A string indicating the description for the workflow definition.
Key	A string indicating the reference key for the workflow definition. The type of information contained in this field will vary depending on the *WorkflowType*. If the *WorkflowType* is *Enrollment* or *Revocation*, this field will contain the Keyfactor Command reference ID for the certificate template.
KeyDisplayName	A string indicating the friendly name defined in Keyfactor Command for the certificate template.
IsPublished	A Boolean indicating whether the workflow definition has been published (true) or not (false). A workflow definition must be published to activate it. For a newly created workflow, this will be *false*.
WorkflowType	A string indicating the type of workflow definition. The currently supported types are: • Enrollment • Revocation
Steps	An array of objects indicating the steps in the workflow definition. The contents of each step will vary depending on the type of workflow and the type of step. For a newly created workflow, there will be no data in this value. Possible steps include:

Name	Description
Id	A string indicating the Keyfactor Command reference GUID of the workflow definition step.
DisplayName	A string indicating the display name for the step.
UniqueName	A string indicating the unique name for the step. This value must be unique among the steps in the particular workflow definition. It is intended to be used as a user-friendly reference ID.
ExtensionName	A string indicating the type of step. The currently supported types are: • **Email** Send an email message. This is a separate email message from those typically sent as part of a *Require Approval* step. You might send an email message as part of an enrollment request to notify approvers that a new request needs

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td>approval. The email messages can be customized to provide detailed information about, for example, the certificate request. • **PowerShell** Run PowerShell commands within the confines of the workflow to populate variables with information to pass back to the workflow. The PowerShell script contents are embedded within the step. This step does not call out to an external file. This provides a high level of security by greatly limiting the number of standard PowerShell cmdlets that can be executed by the workflow step. A small number of PowerShell cmdlets have been white listed to allow them to be included in workflow steps of this type, including: • Where-Object • ForEach-Object • Get-Command • **CustomPowerShell** Run a PowerShell script. The script contents are in a file placed in the ExtensionLibrary\Workflow directory or a subdirectory of it on the Keyfactor Command server under the install directory for Keyfactor Command. By default, this is: C:\Program Files\Keyfactor\Keyfactor Platform\ExtensionLibrary\Workflow The file must have an extension of .ps1. A sample PowerShell script is provided in the Workflow directory (CustomPowershellExample.ps1). • **RequireApproval** Require approval for a workflow step before the step can be completed. The require approval step applies to certificate enrollments, renewals, and revocations and can require approval from just one approver or multiple approvers. The workflow will be suspended at this point until the correct number of approvals from users with the correct security roles is received or until one deny is received before continuing to the next step. As part of this step, an email message is sent indicating whether the step was approved or denied—typically to the requester. This step does not include logic to send an email initiating the approval process (letting users know something needs approval). Use an *Email* type step for this. **Important:** Workflows are not supported with CA delegation when they contain steps that require approval. For more information, see the CA configuration Authorization Methods Tab on page 322 in the *Keyfactor Command Reference Guide*.</td></tr></table>

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td> **Note:** The users that you send email to initiating the approval process must be members of a security role that is allowed to submit signals (approve/deny) for the workflow in order to approve or deny the request. **Tip:** The workflow builder does not include a step to send a notification to the requester of a certificate once the certificate is issued by the CA (as opposed to approved in Keyfactor Command). Use the issued alerts for this (see Issued Request Alert Operations on page 170 in the *Keyfactor Command Reference Guide*). • **RESTRequest** Run a REST (API) request. The REST request contents are embedded within the step. It does not call out to an external file. • **EnrollmentAgent** On an enrollment (either CSR or PFX), create a resigned CSR to prepare an updated enrollment request for delivery to a Microsoft CA after a previous step in the workflow has been used to update either the SANs in the initial request, subject (DN) in the initial request or both. This step must be placed later in the workflow than the step(s) to modify the SANs and/or subject. The SANs and subject may be modified with either of the PowerShell step types or a custom step type. The step creates a new CSR using the same public key as the original CSR using the updated SAN and/or subject values. It signs the new CSR with the certificate provided in the step's configuration. For this type of step you will need an enrollment agent certificate available as a PKCS#12 (.PFX) file with included private key to import into Keyfactor Command. This can be a user certificate or a computer certificate (e.g. generated from a copy of the "Enrollment Agent" template or the "Enrollment Agent (Computer)" template) and must have a Certificate Request Agent EKU. Note that the built-in "Enrollment Agent" and "Enrollment Agent (Computer)" templates do not allow private keys to be exported by default. You will need a template that allows private key export or will need to manually override private key export to create a certificate with an exportable private key in order to create a PKCS#12 (.PFX) file. **Important:** This step applies to Microsoft CAs only. If this step is added to workflow for requests directed to an EJBCA CA, it will fail on enrollment. Note that EJBCA supports submission of updated SAN or subject details as part of standard functionality.</td></tr></table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>

SubjectFormatter
On an enrollment done through the Keyfactor Windows Enrollment Gateway using a client-side template configured with the Build from this Active Directory information option on the template, this workflow step handles formatting the incoming subject, SANs, and/or SID in the certificate request appropriately such that the enrollment will complete successfully with the target CA and Keyfactor Command template, which is not configured to build from AD. Any Keyfactor Windows Enrollment Gateway using a client-side template configured with the subject as Build from this Active Directory information must be configured with a workflow step of this type on the Keyfactor Command template that has been mapped in the gateway to that template in order to complete an enrollment through the gateway. There are no configuration parameters for the step.

  Important: The template in Keyfactor Command that is mapped to the client-side template configured to build the subject from Active Directory also needs to be configured with three enrollment fields to support handling the incoming subject, SANs, and/or SID. For more information about configuring this, see the Keyfactor Windows Enrollment Gateway Installation and Configuration Guide.
EnrollStep
Enroll for a certificate through Keyfactor Command. The enroll step must always fall as the last step in the workflow, immediately following the EndNOOP step.
NOOPStep
An entry or exit step in which no operation occurs. Steps of this type indicate the start and end of the workflow.
RevokeStep
Revoke a certificate through Keyfactor Command. The revoke step must always fall as the last step in the workflow, immediately following the EndNOOP step.

 Tip: For steps that send email messages, the SMTP settings and sender information come from the standard Keyfactor Command SMTP configuration (see <a>SMTP on page 1814) and are not configured individually in the workflow steps.
</td></tr>
<tr><td>Enabled</td><td>A Boolean indicating whether the step is enabled to run (true) or not (false).</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>ConfigurationParameters</td><td>
An array containing the configuration parameters for the workflow definition step. These will vary depending on the type of workflow and the type of step (see ExtensionName).

Note: There are no ConfigurationParameters for steps of type SubjectFormatter, EnrollStep, NOOPStep, or RevokeStep.

Possible CustomPowerShell parameters include:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>ScriptParameters</td><td>An array of key/value pair strings defining any parameters to be used in the PowerShell script.</td></tr>
<tr><td>ScriptName</td><td>The path and filename for the script to execute. The script needs to be in the ExtensionLibrary\Workflow directory or a subdirectory of it on the Keyfactor Command server under the install directory. By default, this is:
<code>C:\Program Files\Keyfactor\Keyfactor Platform\ExtensionLibrary\Workflow</code>
The file must have an extension of .ps1.
A sample PowerShell script is provided in the Workflow directory (CustomPowershellExample.ps1).</td></tr>
</table>
Tip: Tokens (a.k.a. substitutable special text) may be used in the script parameter value field. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can take the revocation comment entered when the revocation request is approved—$(cmnt)—and append additional data to it using PowerShell.

Possible Email parameters include:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>Subject</td><td>A string indicating the subject line for the email message that will be delivered when the workflow definition step is executed.</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Name	Description
	Name / **Description**

Name

Description

Value	Description
Message	A string indicating the email message that will be delivered when the workflow definition step is executed. The email message is made up of regular text and tokens. If desired, you can format the message body using HTML. For example, for an enrollment pending request notification: "Hello,\n\nA certificate using the $(template) template was requested by $(requester:displayname) from $(CA) on $(subdate). The certificate details include:\n\n<table>\n<tr><th>Certificate Details</th><th>Metadata</th></tr>\n<tr><td>CN: $(request:cn)</td><td>App Owner First Name: $(metadata:AppOwnerFirstName)</td></tr>\n<tr><td>DN: $(request:dn)</td><td>App Owner Last Name: $(metadata:AppOwnerLastName)</td></tr>\n<tr><td>SANs: $(sans)</td><td>App Owner Email Address: $(metadata:AppOwnerEmailAddress)</td></tr>\n<tr><td> </td><td>Business Critical: $(metadata:BusinessCritical)</td></tr>\n\nPlease review this request and issue the certificate as appropriate by going here:\n\n$(reviewlink)\n\nThanks!\n\nYour Certificate Management Tool\n" See Table 13: Tokens for Workflow Definitions in the *Keyfactor Command Reference Guide* for a complete list of available tokens.
Recipients	An array of strings containing the recipients for the workflow definition email. Each email message can have multiple recipients. You can use specific email addresses and/or use tokens to replace an email address variable with actual email addresses at processing time. Available email tokens include: • $(requester:mail) The certificate requester, based on a lookup in Active Directory of the email address associated with the requester on the certificate. • Your custom email-based metadata field, which would be specified similarly to $(metadata:AppOwnerEmailAddress).

Tip: Tokens (a.k.a. substitutable special text) may be used in the subject line,

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td>message and email recipient fields. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can select $(requester) in the workflow definition for an enrollment request and the email message will contain the specific certificate requester name instead of the variable $(requester). Possible **PowerShell** parameters include:<table><tr><th>Value</th><th>Description</th></tr><tr><td>ScriptParameters</td><td>An array of key/value pair strings defining any parameters to be used in the PowerShell script. The key is the name of a custom parameter defined by you and the value is the initial value that should be set for that parameter before the PowerShell is executed, if any. Tokens are supported in the *value*.</td></tr><tr><td>ScriptContent</td><td>A string containing the PowerShell commands to execute. This should be the actual contents of the PowerShell script (the PowerShell commands and supporting components), not a path and filename to an external file.</td></tr></table>**Tip:** Tokens (a.k.a. substitutable special text) may be used in the script parameter value field. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can take the revocation comment entered when the revocation request is approved—$(cmnt)—and append additional data to it using PowerShell. Possible **RequireApproval** parameters include:<table><tr><th>Value</th><th>Description</th></tr><tr><td>MinimumApprovals</td><td>In integer indicating the minimum number of users who must approve the request to allow the request to complete.</td></tr></table></td></tr></table>

Name	Description
	Name / **Description** **Value** / **Description** DenialEmailSubject — A string indicating the subject line for the email message that will be delivered if the request is denied. DenialEmailMessage — A string indicating the email message that will be delivered if the request is denied. The email message is made up of regular text and tokens. If desired, you can format the message body using HTML. See Table 13: Tokens for Workflow Definitions in the *Keyfactor Command Reference Guide* for a complete list of available tokens. DenialEmailRecipients — An array of strings containing the recipients for the denial email. Each email message can have multiple recipients. You can use specific email addresses and/or use tokens to replace an email address variable with actual email addresses at processing time. Available email tokens include: • $(requester:mail) The certificate requester, based on a lookup in Active Directory of the email address associated with the requester on the certificate. • Your custom email-based metadata field, which would be specified similarly to $(metadata:AppOwnerEmailAddress). ApprovalEmailSubject — A string indicating the subject line for the email message that will be delivered if the request is approved. ApprovalEmailMessage — A string indicating the email message that will be delivered if the request is approved. The email message is made up of regular text and tokens. If desired, you can format the message body using HTML.

Name	Description
	Name / **Description**

Value	Description
	See Table 13: Tokens for Workflow Definitions in the *Keyfactor Command Reference Guide* for a complete list of available tokens.
ApprovalEmailRecipients	An array of strings containing the recipients for the approval email. Each email message can have multiple recipients. You can use specific email addresses and/or use tokens to replace an email address variable with actual email addresses at processing time. Available email tokens include: • $(requester:mail) The certificate requester, based on a lookup in Active Directory of the email address associated with the requester on the certificate. • Your custom email-based metadata field, which would be specified similarly to $(metadata:AppOwnerEmailAddress).

Tip: Tokens (a.k.a. substitutable special text) may be used in the subject line, message and email recipient fields. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can select $(requester) in the workflow definition for an enrollment request and the email message will contain the specific certificate requester name instead of the variable $(requester).

Possible **RestRequest** parameters include:

Value	Description
Headers	An array of key/value pair strings containing the header information for the request. The key is the name of the specific request header (for Keyfactor API request headers, see Table 63: Common Request Headers and the specific documentation for

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>each endpoint) and the value is the value that should be set for that header. For a Keyfactor API request, this might look like:

<pre>"Headers": {
   "x-keyfactor-requested-with": [
      "APIClient"
   ],
   "x-keyfactor-api-version": [
      "2"
   ]
}</pre>
Tip: For a Keyfactor API request, version 1 is assumed if no version is specified. Content type and authorization headers do not need to be specified, since those are addressed elsewhere in the configuration.</td></tr>
<tr><td>DataBuck-etProperty</td><td>A string containing the variable that the response from the request will be returned in, if any. You can then reference this parameter from subsequent steps in the workflow.

Tip: The response is stored as a serialized JObject. To make use of only a portion of the response data in your subsequent step, use JSON path syntax. For example, say you returned the data from a GET /Agents request in a variable called MyResponse and you wanted to reference the ClientMachine name for the orchestrator in a subsequent email message. To limit the data to the first result and only the ClientMachine name, in the email message you would enter the following:
<code>$(MyResponse.[0].ClientMachine)</code></td></tr>
<tr><td>Verb</td><td>A string indicating the HTTP verb for the type of request to perform. Supported values are:

• DELETE
• GET</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Name	Description
	Name / **Description** **Value** / **Description** • HEAD • OPTIONS • POST • PUT • TRACE UseBasicAuth: A Boolean indicating whether Basic authentication should be used for the request (True) or not (False). If *UseBasicAuth* is *False*, Windows authentication in the context of the Keyfactor Command application pool user will be used (see Create Active Directory Service Accounts for Keyfactor Command on page 2229 in the *Keyfactor Command Server Installation Guide*). BasicUsername: An array indicating the username information to use for authentication if *UseBasicAuth* is *True*. Supported methods to store credential information are: • Store the credential information in the Keyfactor secrets table. A Keyfactor secret is a user-defined username or password that is encrypted and stored securely in the Keyfactor Command database. • Load the credential information from a PAM provider. See PAM Providers on page 1439 and Privileged Access Management (PAM) on page 640 in the *Keyfactor Command Reference Guide* for more information. **Value** / **Description** SecretValue: A string containing the username defined for basic authentication (in DOMAIN\\username format). Parameters: An array indicating the parameters to supply for PAM authentication. These

Name	Description
	Name / **Description**

Name

Description

Value	Description
	Value / **Description**

Value	Description
	will vary depending on the PAM provider.
Provider	A string indicating the ID of the PAM provider. Use the *GET /PamProviders* method (see GET PAM Providers on page 1455) to retrieve a list of all the PAM providers to determine the ID.

For example, the username stored as a Keyfactor secret will look like:

```
{
   "SecretValue": "KEYEXAMPLE\svc_MyServiceName"
}
```

The username stored as a CyberArk PAM secret will look like (where the Provider value—1 in this example—is the Id value from GET PAM Providers on page 1455 and the Folder and Object reference the folder name and object name in the CyberArk safe):

```
{
   "Provider": "1",
   "Parameters":{
      "Folder":"MyFolderName",
      "Object":"MyWorkflowUsername"
   }
}
```

The username stored as a Delinea PAM secret will look like (where the Provider value—1 in this example—is the Id value from GET PAM Providers on page 1455 and the SecretId is the ID if the secret created in the Delinea secret server for this

Name	Description
	Name / **Description**

Name

Description

Value	Description
	purpose): `{ "Provider": "1", "Parameters":{ "SecretId":"MyUsernameId" } }` Due to its sensitive nature, this value is not returned in responses.
BasicPassword	An array indicating the password information to use for authentication if *UseBasicAuth* is *True*. The syntax is the same as for *BasicUsername*. Due to its sensitive nature, this value is not returned in responses.

URL	A string containing the URL for the request, including tokens, if desired. For a Keyfactor API request, this might look like:
	`https://keyfactor.keyexample.com/KeyfactorAPI/Certificates?pq.queryString=CN%20-contains%20%22appsrvr14%22%20AND%20CertStorePath%20-ne%20NULL`
	Or, with tokens:
	`https://keyfactor.keyexample.com/KeyfactorAPI/Certificates/$(certid)`
	
	Note: To prevent REST requests from being made to inappropriate locations by malicious users, configure a system environment variable of KEYFACTOR_BLOCKED_OUTBOUND_IPS on your Keyfactor Command server pointing to the IP address or range of addresses in CIDR format that you wish to block. Both IPv4 and IPv6 addresses are supported. More than one address or range may be specified in a comma-delimited list. For example:

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>192.168.12.0/24,192.168.14.22/24
When a REST request is made where the URL is either configured to a blocked IP address or resolves via DNS to a blocked IP address, the REST request will fail.</td></tr>
<tr><td>ContentType</td><td>A string indicating the content type for the request. Supported values are:
application/json</td></tr>
<tr><td>RequestContent</td><td>A string containing the body of the REST request, if needed. For a Keyfactor API request, this will vary depending on the request and might look like (for a PUT /Certificates/Metadata request):<pre>{
   "Id": "$(certid)",
   "Metadata":{
      "RevocationComment": "$(cmnt)"
   }
}</pre>Note: This example assumes you have a metadata field called RevocationComment.</td></tr>
</table>
Tip: Tokens (a.k.a. substitutable special text) may be used in the URL and request content fields. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can take the revocation comment entered when the revocation request is approved—$(cmnt)—and insert it into a custom metadata field in the certificate by doing a PUT /Certificates/Metadata request for the $(id).
</td></tr>
<tr><td>Signals</td><td>An array of objects containing data used at the point in the workflow step where the workflow needs to continue based on user input. These will vary depending on the type of workflow and the type of step (see ExtensionName). Possible RequireApproval values are:</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>RoleIds</td><td>An array of integers indicating the security roles whose members are allowed to approve the request.</td></tr>
<tr><td>SignalName</td><td>A string indicating the name of the signal. This value will vary depending on the workflow step. For the built-in Require Approval step, the SignalName is "ApprovalStatus".</td></tr>
</table>
Important: If all the security roles configured for a workflow step are deleted from Keyfactor Command, no users will be able to submit signals for workflow instances initiated with that workflow definition. To remedy this, update the workflow definition with one or more current security roles, re-publish it, and then restart any outstanding workflow instances.
</td></tr>
<tr><td>Conditions</td><td>An object containing conditions indicating whether the step should run (true) or not (false). Conditions may either have a static value of True or False or a token that will have a value of True or False at the time the step is run. More than one condition may be added. If multiple conditions are used in the same step, all conditions must have a value of True at the time the step is evaluated to be run in order for the step to run. If any single condition evaluates to False, the step will not run. Condition values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>Id</td><td>A string indicating the Keyfactor Command reference ID of the condition.</td></tr>
<tr><td>Value</td><td>A string indicating the value of the condition. This should be one of "true", "false", or a token that will be set to either "true" or "false" in an earlier step in the workflow (see <a>Adding or Modifying a Workflow Definition on page 210 in the Keyfactor Command Reference Guide for an example).</td></tr>
</table>
</td></tr>
<tr><td>Outputs</td><td>An array indicating the next step in the workflow. Possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>continue</td><td>A string indicating the UniqueName of the next workflow step in the chain. This value will be null for the final step in the chain.</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Name	Description
DraftVersion	An integer indicating the version number of the workflow definition. If this version number does not match the *PublishedVersion*, changes have been made to the workflow definition that have not yet been published.
PublishedVersion	An integer indicating the currently published version number of the workflow definition. For a newly created workflow, this value will be null.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.31.4 PUT Workflow Definitions Definition ID

The PUT /Workflow/Definitions/{definitionid} method is used to update the name and description for the workflow definition with the specified GUID. This method returns HTTP 200 OK on a success with details about the updated workflow definition.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
WorkflowDefinitions: *Modify*

Note: Only one workflow definition can be created for each combination of **Workflow Type** and **Key** (**Template**). In other words, you cannot have two enrollment or revocation workflow definitions for the same template, though you can have one enrollment workflow definition and one revocation workflow definition for a given template.

Note: If you edit an existing *published* workflow definition, a new version of the workflow definition will be created. If you edit an existing workflow definition which has *never been published*, the existing configuration will be overwritten with the changes you've made—a new version will not be created.

Warning: Any previously populated fields that are not submitted with their full existing data using this method will be cleared of their existing data. When using this method, you should first do a GET to retrieve all the values for the record you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing.

Table 640: PUT Workflow Definitions {definitionid} Input Parameters

Name	In	Description
definitionId	Path	**Required**. A string indicating the Keyfactor Command reference GUID of the workflow definition.
DisplayName	Body	**Required**. A string indicating the display name defined for the workflow definition.
Description	Body	A string indicating the description for the workflow definition.

Table 641: PUT Workflow Definitions {definitionid} Response Body

Name	Description
Id	A string indicating the Keyfactor Command reference GUID of the workflow definition.
DisplayName	A string indicating the display name defined for the workflow definition.
Description	A string indicating the description for the workflow definition.
Key	A string indicating the reference key for the workflow definition. The type of information contained in this field will vary depending on the *WorkflowType*. If the *WorkflowType* is *Enrollment* or *Revocation*, this field will contain the Keyfactor Command reference ID for the certificate template.
KeyDisplayName	A string indicating the friendly name defined in Keyfactor Command for the certificate template.
IsPublished	A Boolean indicating whether the workflow definition has been published (true) or not (false). A workflow definition must be published to activate it. For a newly created workflow, this will be *false*.
WorkflowType	A string indicating the type of workflow definition. The currently supported types are: • Enrollment • Revocation
Steps	An array of objects indicating the steps in the workflow definition. The contents of each step will vary depending on the type of workflow and the type of step. For a newly created workflow, there will be no data in this value. Possible steps include:

Name	Description
Id	A string indicating the Keyfactor Command reference GUID of the workflow definition step.
DisplayName	A string indicating the display name for the step.
UniqueName	A string indicating the unique name for the step. This value must be unique among the steps in the particular workflow definition. It is intended to be used as a user-friendly reference ID.
ExtensionName	A string indicating the type of step. The currently supported types are: • **Email** Send an email message. This is a separate email message from those typically sent as part of a *Require Approval* step. You might send an email message as part of an enrollment request to notify approvers that a new request needs

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td>approval. The email messages can be customized to provide detailed information about, for example, the certificate request. • **PowerShell** Run PowerShell commands within the confines of the workflow to populate variables with information to pass back to the workflow. The PowerShell script contents are embedded within the step. This step does not call out to an external file. This provides a high level of security by greatly limiting the number of standard PowerShell cmdlets that can be executed by the workflow step. A small number of PowerShell cmdlets have been white listed to allow them to be included in workflow steps of this type, including: • Where-Object • ForEach-Object • Get-Command • **CustomPowerShell** Run a PowerShell script. The script contents are in a file placed in the ExtensionLibrary\Workflow directory or a subdirectory of it on the Keyfactor Command server under the install directory for Keyfactor Command. By default, this is: C:\Program Files\Keyfactor\Keyfactor Platform\ExtensionLibrary\Workflow The file must have an extension of .ps1. A sample PowerShell script is provided in the Workflow directory (CustomPowershellExample.ps1). • **RequireApproval** Require approval for a workflow step before the step can be completed. The require approval step applies to certificate enrollments, renewals, and revocations and can require approval from just one approver or multiple approvers. The workflow will be suspended at this point until the correct number of approvals from users with the correct security roles is received or until one deny is received before continuing to the next step. As part of this step, an email message is sent indicating whether the step was approved or denied—typically to the requester. This step does not include logic to send an email initiating the approval process (letting users know something needs approval). Use an *Email* type step for this. **Important:** Workflows are not supported with CA delegation when they contain steps that require approval. For more information, see the CA configuration Authorization Methods Tab on page 322 in the *Keyfactor Command Reference Guide*.</td></tr></table>

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td> **Note:** The users that you send email to initiating the approval process must be members of a security role that is allowed to submit signals (approve/deny) for the workflow in order to approve or deny the request. **Tip:** The workflow builder does not include a step to send a notification to the requester of a certificate once the certificate is issued by the CA (as opposed to approved in Keyfactor Command). Use the issued alerts for this (see Issued Request Alert Operations on page 170 in the *Keyfactor Command Reference Guide*). • **RESTRequest** Run a REST (API) request. The REST request contents are embedded within the step. It does not call out to an external file. • **EnrollmentAgent** On an enrollment (either CSR or PFX), create a resigned CSR to prepare an updated enrollment request for delivery to a Microsoft CA after a previous step in the workflow has been used to update either the SANs in the initial request, subject (DN) in the initial request or both. This step must be placed later in the workflow than the step(s) to modify the SANs and/or subject. The SANs and subject may be modified with either of the PowerShell step types or a custom step type. The step creates a new CSR using the same public key as the original CSR using the updated SAN and/or subject values. It signs the new CSR with the certificate provided in the step's configuration. For this type of step you will need an enrollment agent certificate available as a PKCS#12 (.PFX) file with included private key to import into Keyfactor Command. This can be a user certificate or a computer certificate (e.g. generated from a copy of the "Enrollment Agent" template or the "Enrollment Agent (Computer)" template) and must have a Certificate Request Agent EKU. Note that the built-in "Enrollment Agent" and "Enrollment Agent (Computer)" templates do not allow private keys to be exported by default. You will need a template that allows private key export or will need to manually override private key export to create a certificate with an exportable private key in order to create a PKCS#12 (.PFX) file. **Important:** This step applies to Microsoft CAs only. If this step is added to workflow for requests directed to an EJBCA CA, it will fail on enrollment. Note that EJBCA supports submission of updated SAN or subject details as part of standard functionality.</td></tr></table>

<table>
<tr><th>Name</th><th>Description</th></tr>

<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>

SubjectFormatter
On an enrollment done through the Keyfactor Windows Enrollment Gateway using a client-side template configured with the Build from this Active Directory information option on the template, this workflow step handles formatting the incoming subject, SANs, and/or SID in the certificate request appropriately such that the enrollment will complete successfully with the target CA and Keyfactor Command template, which is not configured to build from AD. Any Keyfactor Windows Enrollment Gateway using a client-side template configured with the subject as Build from this Active Directory information must be configured with a workflow step of this type on the Keyfactor Command template that has been mapped in the gateway to that template in order to complete an enrollment through the gateway. There are no configuration parameters for the step.

  Important: The template in Keyfactor Command that is mapped to the client-side template configured to build the subject from Active Directory also needs to be configured with three enrollment fields to support handling the incoming subject, SANs, and/or SID. For more information about configuring this, see the Keyfactor Windows Enrollment Gateway Installation and Configuration Guide.
EnrollStep
Enroll for a certificate through Keyfactor Command. The enroll step must always fall as the last step in the workflow, immediately following the EndNOOP step.
NOOPStep
An entry or exit step in which no operation occurs. Steps of this type indicate the start and end of the workflow.
RevokeStep
Revoke a certificate through Keyfactor Command. The revoke step must always fall as the last step in the workflow, immediately following the EndNOOP step.

 Tip: For steps that send email messages, the SMTP settings and sender information come from the standard Keyfactor Command SMTP configuration (see SMTP on page 1814) and are not configured individually in the workflow steps.
</td></tr>
<tr><td>Enabled</td><td>A Boolean indicating whether the step is enabled to run (true) or not (false).</td></tr>
</table>
</td></tr>
</table>

Name	Description

Name	Description
Config-urationPara-meters	An array containing the configuration parameters for the workflow definition step. These will vary depending on the type of workflow and the type of step (see *ExtensionName*). **Note:** There are no ConfigurationParameters for steps of type *SubjectFormatter*, *EnrollStep*, *NOOPStep*, or *RevokeStep*. Possible **CustomPowerShell** parameters include:

Value	Description
ScriptParameters	An array of key/value pair strings defining any parameters to be used in the PowerShell script.
ScriptName	The path and filename for the script to execute. The script needs to be in the ExtensionLibrary\Workflow directory or a subdirectory of it on the Keyfactor Command server under the install directory. By default, this is: `C:\Program Files\Keyfactor\Keyfactor Platform\ExtensionLibrary\Workflow` The file must have an extension of .ps1. A sample PowerShell script is provided in the Workflow directory (CustomPowershellExample.ps1).

Tip: Tokens (a.k.a. substitutable special text) may be used in the script parameter value field. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can take the revocation comment entered when the revocation request is approved—$(cmnt)—and append additional data to it using PowerShell.

Possible **Email** parameters include:

Value	Description
Subject	A string indicating the subject line for the email message that will be delivered when the workflow definition step is executed.

Name	Description
	Name / **Description**

Value	Description
Message	A string indicating the email message that will be delivered when the workflow definition step is executed. The email message is made up of regular text and tokens. If desired, you can format the message body using HTML. For example, for an enrollment pending request notification: "Hello,\n\nA certificate using the $(template) template was requested by $(requester:displayname) from $(CA) on $(subdate). The certificate details include:\n\n<table>\n<tr><th>Certificate Details</th><th>Metadata</th></tr>\n<tr><td>CN: $(request:cn)</td><td>App Owner First Name: $(metadata:AppOwnerFirstName)</td></tr>\n<tr><td>DN: $(request:dn)</td><td>App Owner Last Name: $(metadata:AppOwnerLastName)</td></tr>\n<tr><td>SANs: $(sans)</td><td>App Owner Email Address: $(metadata:AppOwnerEmailAddress)</td></tr>\n<tr><td> </td><td>Business Critical: $(metadata:BusinessCritical)</td></tr>\n\nPlease review this request and issue the certificate as appropriate by going here:\n\n$(reviewlink)\n\nThanks!\n\nYour Certificate Management Tool\n" See Table 13: Tokens for Workflow Definitions in the *Keyfactor Command Reference Guide* for a complete list of available tokens.
Recipients	An array of strings containing the recipients for the workflow definition email. Each email message can have multiple recipients. You can use specific email addresses and/or use tokens to replace an email address variable with actual email addresses at processing time. Available email tokens include: • $(requester:mail) The certificate requester, based on a lookup in Active Directory of the email address associated with the requester on the certificate. • Your custom email-based metadata field, which would be specified similarly to $(metadata:AppOwnerEmailAddress).

Tip: Tokens (a.k.a. substitutable special text) may be used in the subject line,

Name	Description

Name	Description

message and email recipient fields. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can select $(requester) in the workflow definition for an enrollment request and the email message will contain the specific certificate requester name instead of the variable $(requester).

Possible **PowerShell** parameters include:

Value	Description
ScriptParameters	An array of key/value pair strings defining any parameters to be used in the PowerShell script. The key is the name of a custom parameter defined by you and the value is the initial value that should be set for that parameter before the PowerShell is executed, if any. Tokens are supported in the *value*.
ScriptContent	A string containing the PowerShell commands to execute. This should be the actual contents of the PowerShell script (the PowerShell commands and supporting components), not a path and filename to an external file.

Tip: Tokens (a.k.a. substitutable special text) may be used in the script parameter value field. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can take the revocation comment entered when the revocation request is approved—$(cmnt)—and append additional data to it using PowerShell.

Possible **RequireApproval** parameters include:

Value	Description
MinimumApprovals	In integer indicating the minimum number of users who must approve the request to allow the request to complete.

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td><table><tr><th>Value</th><th>Description</th></tr><tr><td>DenialEmailSubject</td><td>A string indicating the subject line for the email message that will be delivered if the request is denied.</td></tr><tr><td>DenialEmailMessage</td><td>A string indicating the email message that will be delivered if the request is denied. The email message is made up of regular text and tokens. If desired, you can format the message body using HTML. See Table 13: Tokens for Workflow Definitions in the Keyfactor Command Reference Guide for a complete list of available tokens.</td></tr><tr><td>DenialEmailRecipients</td><td>An array of strings containing the recipients for the denial email. Each email message can have multiple recipients. You can use specific email addresses and/or use tokens to replace an email address variable with actual email addresses at processing time. Available email tokens include: $(requester:mail) The certificate requester, based on a lookup in Active Directory of the email address associated with the requester on the certificate. - Your custom email-based metadata field, which would be specified similarly to $(metadata:AppOwnerEmailAddress). </td></tr><tr><td>ApprovalEmailSubject</td><td>A string indicating the subject line for the email message that will be delivered if the request is approved.</td></tr><tr><td>ApprovalEmailMessage</td><td>A string indicating the email message that will be delivered if the request is approved. The email message is made up of regular text and tokens. If desired, you can format the message body using HTML.</td></tr></table></td></tr></table>

Name	Description
	Name / **Description**

Value	Description
	See Table 13: Tokens for Workflow Definitions in the *Keyfactor Command Reference Guide* for a complete list of available tokens.
ApprovalEmailRecipients	An array of strings containing the recipients for the approval email. Each email message can have multiple recipients. You can use specific email addresses and/or use tokens to replace an email address variable with actual email addresses at processing time. Available email tokens include: • $(requester:mail) The certificate requester, based on a lookup in Active Directory of the email address associated with the requester on the certificate. • Your custom email-based metadata field, which would be specified similarly to $(metadata:AppOwnerEmailAddress).

Tip: Tokens (a.k.a. substitutable special text) may be used in the subject line, message and email recipient fields. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can select $(requester) in the workflow definition for an enrollment request and the email message will contain the specific certificate requester name instead of the variable $(requester).

Possible **RestRequest** parameters include:

Value	Description
Headers	An array of key/value pair strings containing the header information for the request. The key is the name of the specific request header (for Keyfactor API request headers, see Table 63: Common Request Headers and the specific documentation for

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>each endpoint) and the value is the value that should be set for that header. For a Keyfactor API request, this might look like:

<pre>"Headers": {
   "x-keyfactor-requested-with": [
      "APIClient"
   ],
   "x-keyfactor-api-version": [
      "2"
   ]
}</pre>
Tip: For a Keyfactor API request, version 1 is assumed if no version is specified. Content type and authorization headers do not need to be specified, since those are addressed elsewhere in the configuration.</td></tr>
<tr><td>DataBuck-etProperty</td><td>A string containing the variable that the response from the request will be returned in, if any. You can then reference this parameter from subsequent steps in the workflow.

Tip: The response is stored as a serialized JObject. To make use of only a portion of the response data in your subsequent step, use JSON path syntax. For example, say you returned the data from a GET /Agents request in a variable called MyResponse and you wanted to reference the ClientMachine name for the orchestrator in a subsequent email message. To limit the data to the first result and only the ClientMachine name, in the email message you would enter the following:
<code>$(MyResponse.[0].ClientMachine)</code></td></tr>
<tr><td>Verb</td><td>A string indicating the HTTP verb for the type of request to perform. Supported values are:

• DELETE
• GET</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Name	Description
	Name / **Description** **Value** / **Description** • HEAD • OPTIONS • POST • PUT • TRACE UseBasicAuth: A Boolean indicating whether Basic authentication should be used for the request (True) or not (False). If *UseBasicAuth* is *False*, Windows authentication in the context of the Keyfactor Command application pool user will be used (see Create Active Directory Service Accounts for Keyfactor Command on page 2229 in the *Keyfactor Command Server Installation Guide*). BasicUsername: An array indicating the username information to use for authentication if *UseBasicAuth* is *True*. Supported methods to store credential information are: • Store the credential information in the Keyfactor secrets table. A Keyfactor secret is a user-defined username or password that is encrypted and stored securely in the Keyfactor Command database. • Load the credential information from a PAM provider. See PAM Providers on page 1439 and Privileged Access Management (PAM) on page 640 in the *Keyfactor Command Reference Guide* for more information. **Value** / **Description** SecretValue: A string containing the username defined for basic authentication (in DOMAIN\\username format). Parameters: An array indicating the parameters to supply for PAM authentication. These

Name	Description

	Name / **Description**
	Value / **Description**
	Value / **Description**
	will vary depending on the PAM provider.
	Provider — A string indicating the ID of the PAM provider. Use the *GET /PamProviders* method (see GET PAM Providers on page 1455) to retrieve a list of all the PAM providers to determine the ID.
	For example, the username stored as a Keyfactor secret will look like:
	`{ "SecretValue": "KEYEXAMPLE\svc_MyServiceName" }`
	The username stored as a CyberArk PAM secret will look like (where the Provider value—1 in this example—is the Id value from GET PAM Providers on page 1455 and the Folder and Object reference the folder name and object name in the CyberArk safe):
	`{ "Provider": "1", "Parameters":{ "Folder":"MyFolderName", "Object":"MyWorkflowUsername" } }`
	The username stored as a Delinea PAM secret will look like (where the Provider value—1 in this example—is the Id value from GET PAM Providers on page 1455 and the SecretId is the ID if the secret created in the Delinea secret server for this

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>purpose):
<pre>{
   "Provider": "1",
   "Parameters":{
      "SecretId":"MyUsernameId"
   }
}</pre>
Due to its sensitive nature, this value is not returned in responses.</td></tr>
<tr><td>BasicPass-word</td><td>An array indicating the password information to use for authen-tication if UseBasicAuth is True. The syntax is the same as for BasicUsername.
Due to its sensitive nature, this value is not returned in responses.</td></tr>
<tr><td>URL</td><td>A string containing the URL for the request, including tokens, if desired. For a Keyfactor API request, this might look like:
<code>https://keyfactor.keyexample.com/KeyfactorAPI/Certificates?pq.queryString=CN%20-contains%20%22appsrvr14%22%20AND%20CertStorePath%20-ne%20NULL</code>
Or, with tokens:
<code>https://keyfactor.keyexample.com/KeyfactorAPI/Certificates/$(certid)</code>
Note: To prevent REST requests from being made to inappropriate locations by malicious users, configure a system environment variable of KEYFACTOR_BLOCKED_OUTBOUND_IPS on your Keyfactor Command server pointing to the IP address or range of addresses in CIDR format that you wish to block. Both IPv4 and IPv6 addresses are supported. More than one address or range may be specified in a comma-delimited list. For example:</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>192.168.12.0/24,192.168.14.22/24
When a REST request is made where the URL is either configured to a blocked IP address or resolves via DNS to a blocked IP address, the REST request will fail.</td></tr>
<tr><td>ContentType</td><td>A string indicating the content type for the request. Supported values are:
application/json</td></tr>
<tr><td>RequestContent</td><td>A string containing the body of the REST request, if needed. For a Keyfactor API request, this will vary depending on the request and might look like (for a PUT /Certificates/Metadata request):
<pre>{
   "Id": "$(certid)",
   "Metadata":{
      "RevocationComment": "$(cmnt)"
   }
}</pre>
Note: This example assumes you have a metadata field called RevocationComment.</td></tr>
</table>

Tip: Tokens (a.k.a. substitutable special text) may be used in the URL and request content fields. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can take the revocation comment entered when the revocation request is approved—$(cmnt)—and insert it into a custom metadata field in the certificate by doing a PUT /Certificates/Metadata request for the $(id).
</td></tr>
<tr><td>Signals</td><td>An array of objects containing data used at the point in the workflow step where the workflow needs to continue based on user input. These will vary depending on the type of workflow and the type of step (see ExtensionName). Possible RequireApproval values are:</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>RoleIds</td><td>An array of integers indicating the security roles whose members are allowed to approve the request.</td></tr>
<tr><td>SignalName</td><td>A string indicating the name of the signal. This value will vary depending on the workflow step. For the built-in Require Approval step, the SignalName is "ApprovalStatus".</td></tr>
</table>
Important: If all the security roles configured for a workflow step are deleted from Keyfactor Command, no users will be able to submit signals for workflow instances initiated with that workflow definition. To remedy this, update the workflow definition with one or more current security roles, re-publish it, and then restart any outstanding workflow instances.
</td></tr>
<tr><td>Conditions</td><td>An object containing conditions indicating whether the step should run (true) or not (false). Conditions may either have a static value of True or False or a token that will have a value of True or False at the time the step is run. More than one condition may be added. If multiple conditions are used in the same step, all conditions must have a value of True at the time the step is evaluated to be run in order for the step to run. If any single condition evaluates to False, the step will not run. Condition values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>Id</td><td>A string indicating the Keyfactor Command reference ID of the condition.</td></tr>
<tr><td>Value</td><td>A string indicating the value of the condition. This should be one of "true", "false", or a token that will be set to either "true" or "false" in an earlier step in the workflow (see <a>Adding or Modifying a Workflow Definition on page 210 in the Keyfactor Command Reference Guide for an example).</td></tr>
</table>
</td></tr>
<tr><td>Outputs</td><td>An array indicating the next step in the workflow. Possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>continue</td><td>A string indicating the UniqueName of the next workflow step in the chain. This value will be null for the final step in the chain.</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Name	Description
DraftVersion	An integer indicating the version number of the workflow definition. If this version number does not match the *PublishedVersion*, changes have been made to the workflow definition that have not yet been published.
PublishedVersion	An integer indicating the currently published version number of the workflow definition. For a newly created workflow, this value will be null.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.31.5 GET Workflow Definitions

The GET /Workflow/Definitions method is used to retrieve the list of workflow definitions. This method returns HTTP 200 OK on a success with high level information about the workflow definitions. Use the GET /Workflow/Definitions/{definitionid} method (see GET Workflow Definitions Definition ID on page 1979) to return details including the workflow steps.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
WorkflowDefinitions: *Read*

Table 642: GET Workflow Definitions Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Using the Workflow Definitions Search Feature on page 264. The query fields supported for this endpoint are: • *DisplayName* • *Id* • *IsPublished* (true or false) • *WorkflowType* (Enrollment or Revocation)
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *DisplayName*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 643: GET Workflow Definitions Response Data

Name	Description
Id	A string indicating the Keyfactor Command reference GUID of the workflow definition.
DisplayName	A string indicating the display name defined for the workflow definition.
Key	A string indicating the reference key for the workflow definition. The type of information contained in this field will vary depending on the *WorkflowType*. If the *WorkflowType* is *Enrollment* or *Revocation*, this field will contain the Keyfactor Command reference ID for the certificate template.
KeyDisplayName	A string indicating the friendly name defined in Keyfactor Command for the certificate template.
WorkflowType	A string indicating the type of workflow definition. The currently supported types are: • Enrollment • Revocation
DraftVersion	An integer indicating the version number of the workflow definition. If this version number does not match the *PublishedVersion*, changes have been made to the workflow definition that have not yet been published.
PublishedVersion	An integer indicating the currently published version number of the workflow definition.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.31.6 POST Workflow Definitions

The POST /Workflow/Definitions method is used to create a new workflow definition without any steps. To add steps to the workflow, use the PUT /Workflow/Definitions/{definitionId}/Steps method (see PUT Workflow Definitions Definition ID Steps on page 2035). This method returns HTTP 200 OK on a success with details about the workflow definition.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
WorkflowDefinitions: *Modify*

Note: Only one workflow definition can be created for each combination of **Workflow Type** and **Key** (**Template**). In other words, you cannot have two enrollment or revocation workflow definitions for the same template, though you can have one enrollment workflow definition and one revocation workflow definition for a given template.

Table 644: POST Workflow Definitions Input Parameters

Name	In	Description
DisplayName	Body	**Required**. A string indicating the display name defined for the workflow definition.
Description	Body	A string indicating the description for the workflow definition.
Key	Body	**Required**. A string indicating the reference key for the workflow definition. The type of information contained in this field will vary depending on the *WorkflowType*. If the *WorkflowType* is *Enrollment* or *Revocation*, this field will contain the Keyfactor Command reference ID for the certificate template. Use the GET /Templates method (see GET Templates on page 1922) to retrieve a list or your certificate templates to determine the template ID. This field cannot be modified on an edit.
KeyDisplayName	Body	A string indicating the friendly name defined in Keyfactor Command for the certificate template.
WorkflowType	Body	**Required**. A string indicating the type of workflow definition. The currently supported types are: • Enrollment • Revocation This field cannot be modified on an edit.

Table 645: POST Workflow Definitions Response Body

Name	Description
Id	A string indicating the Keyfactor Command reference GUID of the workflow definition.
DisplayName	A string indicating the display name defined for the workflow definition.
Description	A string indicating the description for the workflow definition.
Key	A string indicating the reference key for the workflow definition. The type of information contained in this field will vary depending on the *WorkflowType*. If the *WorkflowType* is *Enrollment* or *Revocation*, this field will contain the Keyfactor Command reference ID for the certificate template.
KeyDisplayName	A string indicating the friendly name defined in Keyfactor Command for the certificate template.
IsPublished	A Boolean indicating whether the workflow definition has been published (true) or not (false). A workflow definition must be published to activate it. For a newly created workflow, this will be *false*.
WorkflowType	A string indicating the type of workflow definition. The currently supported types are: • Enrollment • Revocation
Steps	An array of objects indicating the steps in the workflow definition. The contents of each step will vary depending on the type of workflow and the type of step. For a newly created workflow, there will be no data in this value. Possible steps include:

Name	Description
Id	A string indicating the Keyfactor Command reference GUID of the workflow definition step.
DisplayName	A string indicating the display name for the step.
UniqueName	A string indicating the unique name for the step. This value must be unique among the steps in the particular workflow definition. It is intended to be used as a user-friendly reference ID.
ExtensionName	A string indicating the type of step. The currently supported types are: • **Email** Send an email message. This is a separate email message from those typically sent as part of a *Require Approval* step. You might send an email message as part of an enrollment request to notify approvers that a new request needs

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td>approval. The email messages can be customized to provide detailed information about, for example, the certificate request. • **PowerShell** Run PowerShell commands within the confines of the workflow to populate variables with information to pass back to the workflow. The PowerShell script contents are embedded within the step. This step does not call out to an external file. This provides a high level of security by greatly limiting the number of standard PowerShell cmdlets that can be executed by the workflow step. A small number of PowerShell cmdlets have been white listed to allow them to be included in workflow steps of this type, including: • Where-Object • ForEach-Object • Get-Command • **CustomPowerShell** Run a PowerShell script. The script contents are in a file placed in the ExtensionLibrary\Workflow directory or a subdirectory of it on the Keyfactor Command server under the install directory for Keyfactor Command. By default, this is: C:\Program Files\Keyfactor\Keyfactor Platform\ExtensionLibrary\Workflow The file must have an extension of .ps1. A sample PowerShell script is provided in the Workflow directory (CustomPowershellExample.ps1). • **RequireApproval** Require approval for a workflow step before the step can be completed. The require approval step applies to certificate enrollments, renewals, and revocations and can require approval from just one approver or multiple approvers. The workflow will be suspended at this point until the correct number of approvals from users with the correct security roles is received or until one deny is received before continuing to the next step. As part of this step, an email message is sent indicating whether the step was approved or denied—typically to the requester. This step does not include logic to send an email initiating the approval process (letting users know something needs approval). Use an *Email* type step for this. **Important:** Workflows are not supported with CA delegation when they contain steps that require approval. For more information, see the CA configuration Authorization Methods Tab on page 322 in the *Keyfactor Command Reference Guide*.</td></tr></table>

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td> **Note:** The users that you send email to initiating the approval process must be members of a security role that is allowed to submit signals (approve/deny) for the workflow in order to approve or deny the request. **Tip:** The workflow builder does not include a step to send a notification to the requester of a certificate once the certificate is issued by the CA (as opposed to approved in Keyfactor Command). Use the issued alerts for this (see Issued Request Alert Operations on page 170 in the *Keyfactor Command Reference Guide*). • **RESTRequest** Run a REST (API) request. The REST request contents are embedded within the step. It does not call out to an external file. • **EnrollmentAgent** On an enrollment (either CSR or PFX), create a resigned CSR to prepare an updated enrollment request for delivery to a Microsoft CA after a previous step in the workflow has been used to update either the SANs in the initial request, subject (DN) in the initial request or both. This step must be placed later in the workflow than the step(s) to modify the SANs and/or subject. The SANs and subject may be modified with either of the PowerShell step types or a custom step type. The step creates a new CSR using the same public key as the original CSR using the updated SAN and/or subject values. It signs the new CSR with the certificate provided in the step's configuration. For this type of step you will need an enrollment agent certificate available as a PKCS#12 (.PFX) file with included private key to import into Keyfactor Command. This can be a user certificate or a computer certificate (e.g. generated from a copy of the "Enrollment Agent" template or the "Enrollment Agent (Computer)" template) and must have a Certificate Request Agent EKU. Note that the built-in "Enrollment Agent" and "Enrollment Agent (Computer)" templates do not allow private keys to be exported by default. You will need a template that allows private key export or will need to manually override private key export to create a certificate with an exportable private key in order to create a PKCS#12 (.PFX) file. **Important:** This step applies to Microsoft CAs only. If this step is added to workflow for requests directed to an EJBCA CA, it will fail on enrollment. Note that EJBCA supports submission of updated SAN or subject details as part of standard functionality.</td></tr></table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>

SubjectFormatter
On an enrollment done through the Keyfactor Windows Enrollment Gateway using a client-side template configured with the Build from this Active Directory information option on the template, this workflow step handles formatting the incoming subject, SANs, and/or SID in the certificate request appropriately such that the enrollment will complete successfully with the target CA and Keyfactor Command template, which is not configured to build from AD. Any Keyfactor Windows Enrollment Gateway using a client-side template configured with the subject as Build from this Active Directory information must be configured with a workflow step of this type on the Keyfactor Command template that has been mapped in the gateway to that template in order to complete an enrollment through the gateway. There are no configuration parameters for the step.

  Important: The template in Keyfactor Command that is mapped to the client-side template configured to build the subject from Active Directory also needs to be configured with three enrollment fields to support handling the incoming subject, SANs, and/or SID. For more information about configuring this, see the Keyfactor Windows Enrollment Gateway Installation and Configuration Guide.
EnrollStep
Enroll for a certificate through Keyfactor Command. The enroll step must always fall as the last step in the workflow, immediately following the EndNOOP step.
NOOPStep
An entry or exit step in which no operation occurs. Steps of this type indicate the start and end of the workflow.
RevokeStep
Revoke a certificate through Keyfactor Command. The revoke step must always fall as the last step in the workflow, immediately following the EndNOOP step.

 Tip: For steps that send email messages, the SMTP settings and sender information come from the standard Keyfactor Command SMTP configuration (see SMTP on page 1814) and are not configured individually in the workflow steps.
</td></tr>
<tr><td>Enabled</td><td>A Boolean indicating whether the step is enabled to run (true) or not (false).</td></tr>
</table>
</td></tr>
</table>

Name	Description

Name	Description
ConfigurationParameters	An array containing the configuration parameters for the workflow definition step. These will vary depending on the type of workflow and the type of step (see *ExtensionName*). **Note:** There are no ConfigurationParameters for steps of type *SubjectFormatter*, *EnrollStep*, *NOOPStep*, or *RevokeStep*. Possible **CustomPowerShell** parameters include:

Value	Description
ScriptParameters	An array of key/value pair strings defining any parameters to be used in the PowerShell script.
ScriptName	The path and filename for the script to execute. The script needs to be in the ExtensionLibrary\Workflow directory or a subdirectory of it on the Keyfactor Command server under the install directory. By default, this is: `C:\Program Files\Keyfactor\Keyfactor Platform\ExtensionLibrary\Workflow` The file must have an extension of .ps1. A sample PowerShell script is provided in the Workflow directory (CustomPowershellExample.ps1).

Tip: Tokens (a.k.a. substitutable special text) may be used in the script parameter value field. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can take the revocation comment entered when the revocation request is approved—$(cmnt)—and append additional data to it using PowerShell.

Possible **Email** parameters include:

Value	Description
Subject	A string indicating the subject line for the email message that will be delivered when the workflow definition step is executed.

Name	Description
	Name / **Description**

Name

Description

Value	Description
Message	A string indicating the email message that will be delivered when the workflow definition step is executed. The email message is made up of regular text and tokens. If desired, you can format the message body using HTML. For example, for an enrollment pending request notification: "Hello,\n\nA certificate using the $(template) template was requested by $(requester:displayname) from $(CA) on $(subdate). The certificate details include:\n\n<table>\n<tr><th>Certificate Details</th><th>Metadata</th></tr>\n<tr><td>CN: $(request:cn)</td><td>App Owner First Name: $(metadata:AppOwnerFirstName)</td></tr>\n<tr><td>DN: $(request:dn)</td><td>App Owner Last Name: $(metadata:AppOwnerLastName)</td></tr>\n<tr><td>SANs: $(sans)</td><td>App Owner Email Address: $(metadata:AppOwnerEmailAddress)</td></tr>\n<tr><td> </td><td>Business Critical: $(metadata:BusinessCritical)</td></tr>\n\nPlease review this request and issue the certificate as appropriate by going here:\n\n$(reviewlink)\n\nThanks!\n\nYour Certificate Management Tool\n" See Table 13: Tokens for Workflow Definitions in the *Keyfactor Command Reference Guide* for a complete list of available tokens.
Recipients	An array of strings containing the recipients for the workflow definition email. Each email message can have multiple recipients. You can use specific email addresses and/or use tokens to replace an email address variable with actual email addresses at processing time. Available email tokens include: • $(requester:mail) The certificate requester, based on a lookup in Active Directory of the email address associated with the requester on the certificate. • Your custom email-based metadata field, which would be specified similarly to $(metadata:AppOwnerEmailAddress).

Tip: Tokens (a.k.a. substitutable special text) may be used in the subject line,

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
message and email recipient fields. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can select $(requester) in the workflow definition for an enrollment request and the email message will contain the specific certificate requester name instead of the variable $(requester).

Possible PowerShell parameters include:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>ScriptParameters</td><td>An array of key/value pair strings defining any parameters to be used in the PowerShell script. The key is the name of a custom parameter defined by you and the value is the initial value that should be set for that parameter before the PowerShell is executed, if any. Tokens are supported in the value.</td></tr>
<tr><td>ScriptContent</td><td>A string containing the PowerShell commands to execute. This should be the actual contents of the PowerShell script (the PowerShell commands and supporting components), not a path and filename to an external file.</td></tr>
</table>
Tip: Tokens (a.k.a. substitutable special text) may be used in the script parameter value field. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can take the revocation comment entered when the revocation request is approved—$(cmnt)—and append additional data to it using PowerShell.

Possible RequireApproval parameters include:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>MinimumApprovals</td><td>In integer indicating the minimum number of users who must approve the request to allow the request to complete.</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td><table><tr><th>Value</th><th>Description</th></tr><tr><td>DenialEmailSubject</td><td>A string indicating the subject line for the email message that will be delivered if the request is denied.</td></tr><tr><td>DenialEmailMessage</td><td>A string indicating the email message that will be delivered if the request is denied. The email message is made up of regular text and tokens. If desired, you can format the message body using HTML. See Table 13: Tokens for Workflow Definitions in the Keyfactor Command Reference Guide for a complete list of available tokens.</td></tr><tr><td>DenialEmailRecipients</td><td>An array of strings containing the recipients for the denial email. Each email message can have multiple recipients. You can use specific email addresses and/or use tokens to replace an email address variable with actual email addresses at processing time. Available email tokens include: $(requester:mail) The certificate requester, based on a lookup in Active Directory of the email address associated with the requester on the certificate. - Your custom email-based metadata field, which would be specified similarly to $(metadata:AppOwnerEmailAddress). </td></tr><tr><td>ApprovalEmailSubject</td><td>A string indicating the subject line for the email message that will be delivered if the request is approved.</td></tr><tr><td>ApprovalEmailMessage</td><td>A string indicating the email message that will be delivered if the request is approved. The email message is made up of regular text and tokens. If desired, you can format the message body using HTML.</td></tr></table></td></tr></table>

Name	Description
	Name / **Description**

Value	Description
	See Table 13: Tokens for Workflow Definitions in the *Keyfactor Command Reference Guide* for a complete list of available tokens.
ApprovalEmailRecipients	An array of strings containing the recipients for the approval email. Each email message can have multiple recipients. You can use specific email addresses and/or use tokens to replace an email address variable with actual email addresses at processing time. Available email tokens include: • $(requester:mail) The certificate requester, based on a lookup in Active Directory of the email address associated with the requester on the certificate. • Your custom email-based metadata field, which would be specified similarly to $(metadata:AppOwnerEmailAddress).

Tip: Tokens (a.k.a. substitutable special text) may be used in the subject line, message and email recipient fields. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can select $(requester) in the workflow definition for an enrollment request and the email message will contain the specific certificate requester name instead of the variable $(requester).

Possible **RestRequest** parameters include:

Value	Description
Headers	An array of key/value pair strings containing the header information for the request. The key is the name of the specific request header (for Keyfactor API request headers, see Table 63: Common Request Headers and the specific documentation for

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>each endpoint) and the value is the value that should be set for that header. For a Keyfactor API request, this might look like:

<pre>"Headers": {
   "x-keyfactor-requested-with": [
      "APIClient"
   ],
   "x-keyfactor-api-version": [
      "2"
   ]
}</pre>
Tip: For a Keyfactor API request, version 1 is assumed if no version is specified. Content type and authorization headers do not need to be specified, since those are addressed elsewhere in the configuration.</td></tr>
<tr><td>DataBuck-etProperty</td><td>A string containing the variable that the response from the request will be returned in, if any. You can then reference this parameter from subsequent steps in the workflow.

Tip: The response is stored as a serialized JObject. To make use of only a portion of the response data in your subsequent step, use JSON path syntax. For example, say you returned the data from a GET /Agents request in a variable called MyResponse and you wanted to reference the ClientMachine name for the orchestrator in a subsequent email message. To limit the data to the first result and only the ClientMachine name, in the email message you would enter the following:
<code>$(MyResponse.[0].ClientMachine)</code></td></tr>
<tr><td>Verb</td><td>A string indicating the HTTP verb for the type of request to perform. Supported values are:

• DELETE
• GET</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>

HEAD
OPTIONS
POST
PUT
TRACE

</td></tr>
<tr><td>UseBasicAuth</td><td>A Boolean indicating whether Basic authentication should be used for the request (True) or not (False).
If UseBasicAuth is False, Windows authentication in the context of the Keyfactor Command application pool user will be used (see Create Active Directory Service Accounts for Keyfactor Command on page 2229 in the Keyfactor Command Server Installation Guide).</td></tr>
<tr><td>BasicUsername</td><td>An array indicating the username information to use for authentication if UseBasicAuth is True.
Supported methods to store credential information are:

Store the credential information in the Keyfactor secrets table.
A Keyfactor secret is a user-defined username or password that is encrypted and stored securely in the Keyfactor Command database.
Load the credential information from a PAM provider.
See PAM Providers on page 1439 and Privileged Access Management (PAM) on page 640 in the Keyfactor Command Reference Guide for more information.

<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>SecretValue</td><td>A string containing the username defined for basic authentication (in DOMAIN\\username format).</td></tr>
<tr><td>Parameters</td><td>An array indicating the parameters to supply for PAM authentication. These</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Name	Description

	Name / **Description**
	Value / **Description**
	Value / **Description**
	will vary depending on the PAM provider.
	Provider — A string indicating the ID of the PAM provider. Use the *GET /PamProviders* method (see GET PAM Providers on page 1455) to retrieve a list of all the PAM providers to determine the ID.
	For example, the username stored as a Keyfactor secret will look like:
	`{ "SecretValue": "KEYEXAMPLE\svc_MyServiceName" }`
	The username stored as a CyberArk PAM secret will look like (where the Provider value—1 in this example—is the Id value from GET PAM Providers on page 1455 and the Folder and Object reference the folder name and object name in the CyberArk safe):
	`{ "Provider": "1", "Parameters":{ "Folder":"MyFolderName", "Object":"MyWorkflowUsername" } }`
	The username stored as a Delinea PAM secret will look like (where the Provider value—1 in this example—is the Id value from GET PAM Providers on page 1455 and the SecretId is the ID if the secret created in the Delinea secret server for this

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>purpose):

<pre>{
   "Provider": "1",
   "Parameters":{
      "SecretId":"MyUsernameId"
   }
}</pre>
Due to its sensitive nature, this value is not returned in responses.</td></tr>
<tr><td>BasicPass-word</td><td>An array indicating the password information to use for authen-tication if UseBasicAuth is True. The syntax is the same as for BasicUsername.
Due to its sensitive nature, this value is not returned in responses.</td></tr>
<tr><td>URL</td><td>A string containing the URL for the request, including tokens, if desired. For a Keyfactor API request, this might look like:
<code>https://keyfactor.keyexample.com/KeyfactorAPI/Certificates?pq.queryString=CN%20-contains%20%22appsrvr14%22%20AND%20CertStorePath%20-ne%20NULL</code>
Or, with tokens:
<code>https://keyfactor.keyexample.com/KeyfactorAPI/Certificates/$(certid)</code>

Note: To prevent REST requests from being made to inappropriate locations by malicious users, configure a system environment variable of KEYFACTOR_BLOCKED_OUTBOUND_IPS on your Keyfactor Command server pointing to the IP address or range of addresses in CIDR format that you wish to block. Both IPv4 and IPv6 addresses are supported. More than one address or range may be specified in a comma-delimited list. For example:</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>192.168.12.0/24,192.168.14.22/24
When a REST request is made where the URL is either configured to a blocked IP address or resolves via DNS to a blocked IP address, the REST request will fail.</td></tr>
<tr><td>ContentType</td><td>A string indicating the content type for the request. Supported values are:
application/json</td></tr>
<tr><td>RequestContent</td><td>A string containing the body of the REST request, if needed. For a Keyfactor API request, this will vary depending on the request and might look like (for a PUT /Certificates/Metadata request):
<pre>{
   "Id": "$(certid)",
   "Metadata":{
      "RevocationComment": "$(cmnt)"
   }
}</pre>
Note: This example assumes you have a metadata field called RevocationComment.</td></tr>
</table>

Tip: Tokens (a.k.a. substitutable special text) may be used in the URL and request content fields. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can take the revocation comment entered when the revocation request is approved—$(cmnt)—and insert it into a custom metadata field in the certificate by doing a PUT /Certificates/Metadata request for the $(id).
</td></tr>
<tr><td>Signals</td><td>An array of objects containing data used at the point in the workflow step where the workflow needs to continue based on user input. These will vary depending on the type of workflow and the type of step (see ExtensionName). Possible RequireApproval values are:</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>RoleIds</td><td>An array of integers indicating the security roles whose members are allowed to approve the request.</td></tr>
<tr><td>SignalName</td><td>A string indicating the name of the signal. This value will vary depending on the workflow step. For the built-in Require Approval step, the SignalName is "ApprovalStatus".</td></tr>
</table>
Important: If all the security roles configured for a workflow step are deleted from Keyfactor Command, no users will be able to submit signals for workflow instances initiated with that workflow definition. To remedy this, update the workflow definition with one or more current security roles, re-publish it, and then restart any outstanding workflow instances.
</td></tr>
<tr><td>Conditions</td><td>An object containing conditions indicating whether the step should run (true) or not (false). Conditions may either have a static value of True or False or a token that will have a value of True or False at the time the step is run. More than one condition may be added. If multiple conditions are used in the same step, all conditions must have a value of True at the time the step is evaluated to be run in order for the step to run. If any single condition evaluates to False, the step will not run. Condition values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>Id</td><td>A string indicating the Keyfactor Command reference ID of the condition.</td></tr>
<tr><td>Value</td><td>A string indicating the value of the condition. This should be one of "true", "false", or a token that will be set to either "true" or "false" in an earlier step in the workflow (see <a>Adding or Modifying a Workflow Definition on page 210 in the Keyfactor Command Reference Guide for an example).</td></tr>
</table>
</td></tr>
<tr><td>Outputs</td><td>An array indicating the next step in the workflow. Possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>continue</td><td>A string indicating the UniqueName of the next workflow step in the chain. This value will be null for the final step in the chain.</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Name	Description
DraftVersion	An integer indicating the version number of the workflow definition. If this version number does not match the *PublishedVersion*, changes have been made to the workflow definition that have not yet been published.
PublishedVersion	An integer indicating the currently published version number of the workflow definition. For a newly created workflow, this value will be null.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.31.7 GET Workflow Definitions Steps

The GET /Workflow/Definitions/Steps method is used to retrieve the workflow definition step structure for the workflow definition steps. This method returns HTTP 200 OK on a success with information about the structure of the workflow definition steps.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
WorkflowDefinitions: *Read*

Table 646: GET Workflow Definitions Steps Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Using the Workflow Definitions Search Feature on page 264. The query fields supported for this endpoint are *DisplayName*, *ExtensionName*, and *SupportedWorkflowTypes*.
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *DisplayName*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 647: GET Workflow Definitions Steps Response Data

Name	Description
DisplayName	A string indicating the display name of the workflow definition step.
ExtensionName	A string indicating the extension name of the workflow definition step. The built-in extension names are: • **Email**—Send an email message. This is a separate email message from those typically sent as part of a *RequireApproval* step. • **EnrollStep**—Enroll for a certificate through Keyfactor Command. • **NOOPStep**—An entry or exit step in which no operation occurs. Steps of this type indicate the start and end of the workflow. • **PowerShell**—Run a PowerShell script. The script contents are embedded within the step. It does not call out to an external file. • **RequireApproval**—Require approval for a workflow step before the step can be completed. This step includes logic to gather the correct number of approvals from the users with the correct security roles and to send an email message indicating whether the step was approved or denied. This step does not include logic to send an email initiating the approval process. Use an *Email* type for this. **Important:** Workflows are not supported with CA delegation when they contain steps that require approval. For more information, see the CA configuration Authorization Methods Tab on page 322 in the *Keyfactor Command Reference Guide*. • **RestRequest**—Run a REST request. The REST request contents are embedded within the step. It does not call out to an external file. • **RevokeStep**—Revoke a certificate through Keyfactor Command.
SupportedWorkflowTypes	An array containing a list of the workflow types supported by the workflow definition step. Possible built-in values are: • Enrollment • Revocation
ConfigurationParametersDefinition	An object containing the configuration parameters for the workflow definition step. These will vary depending on the step.
SignalsDefinition	An object containing the signals defined for the workflow definition step. These will vary depending on the step.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.31.8 GET Workflow Definitions Types

The GET /Workflow/Definitions/Types method is used to retrieve the workflow definition types that have been defined for use. This method returns HTTP 200 OK on a success with information about the defined workflow definition types.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: WorkflowDefinitions: *Read*

Table 648: GET Workflow Definitions Types Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Using the Workflow Definitions Search Feature on page 264. The query field supported for this endpoint is *Name*.
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *WorkflowType*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 649: GET Workflow Definitions Types Response Data

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>WorkflowType</td><td>A string indicating the display name of the workflow type.</td></tr>
<tr><td>KeyType</td><td>A string indicating the key type for the workflow. The built-in enrollment and revocation workflows use Templates as the key type.</td></tr>
<tr><td>ContextParameters</td><td>An object containing the tokens that the workflow type provider has the ability to replace. These will vary depending on the workflow type.</td></tr>
<tr><td>BuiltInSteps</td><td>An object containing the information about the built-in step(s) for the workflow type (e.g. the enrollment step of the enrollment type). Possible steps include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>DisplayName</td><td>A string indicating the display name for the step.</td></tr>
<tr><td>ExtensionName</td><td>A string indicating the extension name for the step. The built-in extensions are:
EnrollStep
RevokeStep</td></tr>
<tr><td>Outputs</td><td>An array containing the outputs for the workflow definition step. For the built-in steps, the only output is an indicator for the next step in the workflow or that the workflow is complete.</td></tr>
<tr><td>ConfigurationParametersDefinition</td><td>An array containing the configuration parameters for the workflow definition step. These will vary depending on the step.</td></tr>
<tr><td>SignalsDefinition</td><td>An array containing the signals defined for the workflow definition step. These will vary depending on the step.</td></tr>
</table></td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.31.9 PUT Workflow Definitions Definition ID Steps

The PUT /Workflow/Definitions/{definitionid}/Steps method is used to add or update the workflow steps for the workflow definition with the specified GUID. This method returns HTTP 200 OK on a success with details about the updated workflow definition.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: WorkflowDefinitions: *Modify*

Note: If you edit an existing *published* workflow definition, a new version of the workflow definition will be created. If you edit an existing workflow definition which has *never been published*, the existing configuration will be overwritten with the changes you've made—a new version will not be created.

Warning: Any previously populated fields that are not submitted with their full existing data using this method will be cleared of their existing data. When using this method, you should first do a GET to retrieve all the values for the record you want to update, enter corrected data into the field(s) you want to update, and then submit all the fields using PUT, including the fields that contain values but which you are not changing.

Table 650: PUT Workflow Definitions {definitionid} Steps Input Parameters

Name	In	Description
definitionId	Path	**Required**. A string indicating the Keyfactor Command reference GUID of the workflow definition to update. Use the *GET /Workflow/Definitions* method (see GET Workflow Definitions on page 2013) to retrieve a list of all the workflow definitions to determine the GUID.

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>request</td><td>Body</td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>DisplayName</td><td>A string indicating the display name for the step.</td></tr>
<tr><td>UniqueName</td><td>A string indicating the unique name for the step. This value must be unique among the steps in the particular workflow definition. It is intended to be used as a user-friendly reference ID.</td></tr>
<tr><td>ExtensionName</td><td>A string indicating the type of step. The currently supported types are:
Email
Send an email message. This is a separate email message from those typically sent as part of a Require Approval step. You might send an email message as part of an enrollment request to notify approvers that a new request needs approval. The email messages can be customized to provide detailed information about, for example, the certificate request.
PowerShell
Run PowerShell commands within the confines of the workflow to populate variables with information to pass back to the workflow. The PowerShell script contents are embedded within the step. This step does not call out to an external file. This provides a high level of security by greatly limiting the number of standard PowerShell cmdlets that can be executed by the workflow step. A small number of PowerShell cmdlets have been white listed to allow them to be included in workflow steps of this type, including:
Where-Object
ForEach-Object
Get-Command
CustomPowerShell
Run a PowerShell script. The script contents are in a file placed in the ExtensionLibrary\Workflow directory or a subdirectory of it on the Keyfactor Command server under the install directory for Keyfactor Command. By default, this is:
<code>C:\Program Files\Keyfactor\Keyfactor Platform\ExtensionLibrary\Workflow</code>
The file must have an extension of .ps1. A sample PowerShell script is provided in the Workflow directory (CustomPowershellExample.ps1).
RequireApproval
Require approval for a workflow step before the step can be completed. The require approval step applies to certificate enrollments, renewals, and revocations and can require approval from just one approver or multiple approvers. The workflow will be suspended at this point until the correct number of approvals from users with the correct security roles is received or until one deny is received before continuing to the next step. As part of this step, an email message is sent indicating whether the step was approved or denied—typically to the requester. This step does not include logic to send an email initiating the approval process (letting users know something needs approval). Use an Email type step for this.
Important: Workflows are not supported with CA delegation</td></tr>
</table>
</td></tr>
</table>

Table 651: PUT Workflow Definitions {definitionid} Steps Response Body

Name	Description
Id	A string indicating the Keyfactor Command reference GUID of the workflow definition.
DisplayName	A string indicating the display name defined for the workflow definition.
Description	A string indicating the description for the workflow definition.
Key	A string indicating the reference key for the workflow definition. The type of information contained in this field will vary depending on the *WorkflowType*. If the *WorkflowType* is *Enrollment* or *Revocation*, this field will contain the Keyfactor Command reference ID for the certificate template.
KeyDisplayName	A string indicating the friendly name defined in Keyfactor Command for the certificate template.
IsPublished	A Boolean indicating whether the workflow definition has been published (true) or not (false). A workflow definition must be published to activate it. For a newly created workflow, this will be *false*.
WorkflowType	A string indicating the type of workflow definition. The currently supported types are: • Enrollment • Revocation
Steps	An array of objects indicating the steps in the workflow definition. The contents of each step will vary depending on the type of workflow and the type of step. For a newly created workflow, there will be no data in this value. Possible steps include:

Name	Description
Id	A string indicating the Keyfactor Command reference GUID of the workflow definition step.
DisplayName	A string indicating the display name for the step.
UniqueName	A string indicating the unique name for the step. This value must be unique among the steps in the particular workflow definition. It is intended to be used as a user-friendly reference ID.
ExtensionName	A string indicating the type of step. The currently supported types are: • **Email** Send an email message. This is a separate email message from those typically sent as part of a *Require Approval* step. You might send an email message as part of an enrollment request to notify approvers that a new request needs

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td>approval. The email messages can be customized to provide detailed information about, for example, the certificate request. • **PowerShell** Run PowerShell commands within the confines of the workflow to populate variables with information to pass back to the workflow. The PowerShell script contents are embedded within the step. This step does not call out to an external file. This provides a high level of security by greatly limiting the number of standard PowerShell cmdlets that can be executed by the workflow step. A small number of PowerShell cmdlets have been white listed to allow them to be included in workflow steps of this type, including: • Where-Object • ForEach-Object • Get-Command • **CustomPowerShell** Run a PowerShell script. The script contents are in a file placed in the ExtensionLibrary\Workflow directory or a subdirectory of it on the Keyfactor Command server under the install directory for Keyfactor Command. By default, this is: C:\Program Files\Keyfactor\Keyfactor Platform\ExtensionLibrary\Workflow The file must have an extension of .ps1. A sample PowerShell script is provided in the Workflow directory (CustomPowershellExample.ps1). • **RequireApproval** Require approval for a workflow step before the step can be completed. The require approval step applies to certificate enrollments, renewals, and revocations and can require approval from just one approver or multiple approvers. The workflow will be suspended at this point until the correct number of approvals from users with the correct security roles is received or until one deny is received before continuing to the next step. As part of this step, an email message is sent indicating whether the step was approved or denied—typically to the requester. This step does not include logic to send an email initiating the approval process (letting users know something needs approval). Use an *Email* type step for this. **Important:** Workflows are not supported with CA delegation when they contain steps that require approval. For more information, see the CA configuration Authorization Methods Tab on page 322 in the *Keyfactor Command Reference Guide*.</td></tr></table>

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td> **Note:** The users that you send email to initiating the approval process must be members of a security role that is allowed to submit signals (approve/deny) for the workflow in order to approve or deny the request. **Tip:** The workflow builder does not include a step to send a notification to the requester of a certificate once the certificate is issued by the CA (as opposed to approved in Keyfactor Command). Use the issued alerts for this (see Issued Request Alert Operations on page 170 in the *Keyfactor Command Reference Guide*). • **RESTRequest** Run a REST (API) request. The REST request contents are embedded within the step. It does not call out to an external file. • **EnrollmentAgent** On an enrollment (either CSR or PFX), create a resigned CSR to prepare an updated enrollment request for delivery to a Microsoft CA after a previous step in the workflow has been used to update either the SANs in the initial request, subject (DN) in the initial request or both. This step must be placed later in the workflow than the step(s) to modify the SANs and/or subject. The SANs and subject may be modified with either of the PowerShell step types or a custom step type. The step creates a new CSR using the same public key as the original CSR using the updated SAN and/or subject values. It signs the new CSR with the certificate provided in the step's configuration. For this type of step you will need an enrollment agent certificate available as a PKCS#12 (.PFX) file with included private key to import into Keyfactor Command. This can be a user certificate or a computer certificate (e.g. generated from a copy of the "Enrollment Agent" template or the "Enrollment Agent (Computer)" template) and must have a Certificate Request Agent EKU. Note that the built-in "Enrollment Agent" and "Enrollment Agent (Computer)" templates do not allow private keys to be exported by default. You will need a template that allows private key export or will need to manually override private key export to create a certificate with an exportable private key in order to create a PKCS#12 (.PFX) file. **Important:** This step applies to Microsoft CAs only. If this step is added to workflow for requests directed to an EJBCA CA, it will fail on enrollment. Note that EJBCA supports submission of updated SAN or subject details as part of standard functionality.</td></tr></table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>

SubjectFormatter
On an enrollment done through the Keyfactor Windows Enrollment Gateway using a client-side template configured with the Build from this Active Directory information option on the template, this workflow step handles formatting the incoming subject, SANs, and/or SID in the certificate request appropriately such that the enrollment will complete successfully with the target CA and Keyfactor Command template, which is not configured to build from AD. Any Keyfactor Windows Enrollment Gateway using a client-side template configured with the subject as Build from this Active Directory information must be configured with a workflow step of this type on the Keyfactor Command template that has been mapped in the gateway to that template in order to complete an enrollment through the gateway. There are no configuration parameters for the step.

  Important: The template in Keyfactor Command that is mapped to the client-side template configured to build the subject from Active Directory also needs to be configured with three enrollment fields to support handling the incoming subject, SANs, and/or SID. For more information about configuring this, see the Keyfactor Windows Enrollment Gateway Installation and Configuration Guide.
EnrollStep
Enroll for a certificate through Keyfactor Command. The enroll step must always fall as the last step in the workflow, immediately following the EndNOOP step.
NOOPStep
An entry or exit step in which no operation occurs. Steps of this type indicate the start and end of the workflow.
RevokeStep
Revoke a certificate through Keyfactor Command. The revoke step must always fall as the last step in the workflow, immediately following the EndNOOP step.

 Tip: For steps that send email messages, the SMTP settings and sender information come from the standard Keyfactor Command SMTP configuration (see SMTP on page 1814) and are not configured individually in the workflow steps.
</td></tr>
<tr><td>Enabled</td><td>A Boolean indicating whether the step is enabled to run (true) or not (false).</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>ConfigurationParameters</td><td>
An array containing the configuration parameters for the workflow definition step. These will vary depending on the type of workflow and the type of step (see ExtensionName).

Note: There are no ConfigurationParameters for steps of type SubjectFormatter, EnrollStep, NOOPStep, or RevokeStep.

Possible CustomPowerShell parameters include:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>ScriptParameters</td><td>An array of key/value pair strings defining any parameters to be used in the PowerShell script.</td></tr>
<tr><td>ScriptName</td><td>The path and filename for the script to execute. The script needs to be in the ExtensionLibrary\Workflow directory or a subdirectory of it on the Keyfactor Command server under the install directory. By default, this is:
<code>C:\Program Files\Keyfactor\Keyfactor Platform\ExtensionLibrary\Workflow</code>
The file must have an extension of .ps1.
A sample PowerShell script is provided in the Workflow directory (CustomPowershellExample.ps1).</td></tr>
</table>
Tip: Tokens (a.k.a. substitutable special text) may be used in the script parameter value field. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can take the revocation comment entered when the revocation request is approved—$(cmnt)—and append additional data to it using PowerShell.

Possible Email parameters include:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>Subject</td><td>A string indicating the subject line for the email message that will be delivered when the workflow definition step is executed.</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Name	Description
	Name / **Description**

Value	Description
Message	A string indicating the email message that will be delivered when the workflow definition step is executed. The email message is made up of regular text and tokens. If desired, you can format the message body using HTML. For example, for an enrollment pending request notification: "Hello,\n\nA certificate using the $(template) template was requested by $(requester:displayname) from $(CA) on $(subdate). The certificate details include:\n\n<table>\n<tr><th>Certificate Details</th><th>Metadata</th></tr>\n<tr><td>CN: $(request:cn)</td><td>App Owner First Name: $(metadata:AppOwnerFirstName)</td></tr>\n<tr><td>DN: $(request:dn)</td><td>App Owner Last Name: $(metadata:AppOwnerLastName)</td></tr>\n<tr><td>SANs: $(sans)</td><td>App Owner Email Address: $(metadata:AppOwnerEmailAddress)</td></tr>\n<tr><td> </td><td>Business Critical: $(metadata:BusinessCritical)</td></tr>\n\nPlease review this request and issue the certificate as appropriate by going here:\n\n$(reviewlink)\n\nThanks!\n\nYour Certificate Management Tool\n" See Table 13: Tokens for Workflow Definitions in the *Keyfactor Command Reference Guide* for a complete list of available tokens.
Recipients	An array of strings containing the recipients for the workflow definition email. Each email message can have multiple recipients. You can use specific email addresses and/or use tokens to replace an email address variable with actual email addresses at processing time. Available email tokens include: • $(requester:mail) The certificate requester, based on a lookup in Active Directory of the email address associated with the requester on the certificate. • Your custom email-based metadata field, which would be specified similarly to $(metadata:AppOwnerEmailAddress).

Tip: Tokens (a.k.a. substitutable special text) may be used in the subject line,

Name	Description

Name	Description

message and email recipient fields. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can select $(requester) in the workflow definition for an enrollment request and the email message will contain the specific certificate requester name instead of the variable $(requester).

Possible **PowerShell** parameters include:

Value	Description
ScriptParameters	An array of key/value pair strings defining any parameters to be used in the PowerShell script. The key is the name of a custom parameter defined by you and the value is the initial value that should be set for that parameter before the PowerShell is executed, if any. Tokens are supported in the *value*.
ScriptContent	A string containing the PowerShell commands to execute. This should be the actual contents of the PowerShell script (the PowerShell commands and supporting components), not a path and filename to an external file.

Tip: Tokens (a.k.a. substitutable special text) may be used in the script parameter value field. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can take the revocation comment entered when the revocation request is approved—$(cmnt)—and append additional data to it using PowerShell.

Possible **RequireApproval** parameters include:

Value	Description
MinimumApprovals	In integer indicating the minimum number of users who must approve the request to allow the request to complete.

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td><table><tr><th>Value</th><th>Description</th></tr><tr><td>DenialEmailSubject</td><td>A string indicating the subject line for the email message that will be delivered if the request is denied.</td></tr><tr><td>DenialEmailMessage</td><td>A string indicating the email message that will be delivered if the request is denied. The email message is made up of regular text and tokens. If desired, you can format the message body using HTML. See Table 13: Tokens for Workflow Definitions in the Keyfactor Command Reference Guide for a complete list of available tokens.</td></tr><tr><td>DenialEmailRecipients</td><td>An array of strings containing the recipients for the denial email. Each email message can have multiple recipients. You can use specific email addresses and/or use tokens to replace an email address variable with actual email addresses at processing time. Available email tokens include: $(requester:mail) The certificate requester, based on a lookup in Active Directory of the email address associated with the requester on the certificate. - Your custom email-based metadata field, which would be specified similarly to $(metadata:AppOwnerEmailAddress). </td></tr><tr><td>ApprovalEmailSubject</td><td>A string indicating the subject line for the email message that will be delivered if the request is approved.</td></tr><tr><td>ApprovalEmailMessage</td><td>A string indicating the email message that will be delivered if the request is approved. The email message is made up of regular text and tokens. If desired, you can format the message body using HTML.</td></tr></table></td></tr></table>

Name	Description
	Name / **Description**

Name

Description

Value	Description
	See Table 13: Tokens for Workflow Definitions in the *Keyfactor Command Reference Guide* for a complete list of available tokens.
ApprovalEmailRecipients	An array of strings containing the recipients for the approval email. Each email message can have multiple recipients. You can use specific email addresses and/or use tokens to replace an email address variable with actual email addresses at processing time. Available email tokens include: • $(requester:mail) The certificate requester, based on a lookup in Active Directory of the email address associated with the requester on the certificate. • Your custom email-based metadata field, which would be specified similarly to $(metadata:AppOwnerEmailAddress).

Tip: Tokens (a.k.a. substitutable special text) may be used in the subject line, message and email recipient fields. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can select $(requester) in the workflow definition for an enrollment request and the email message will contain the specific certificate requester name instead of the variable $(requester).

Possible **RestRequest** parameters include:

Value	Description
Headers	An array of key/value pair strings containing the header information for the request. The key is the name of the specific request header (for Keyfactor API request headers, see Table 63: Common Request Headers and the specific documentation for

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>each endpoint) and the value is the value that should be set for that header. For a Keyfactor API request, this might look like:

<pre>"Headers": {
   "x-keyfactor-requested-with": [
      "APIClient"
   ],
   "x-keyfactor-api-version": [
      "2"
   ]
}</pre>
  Tip: For a Keyfactor API request, version 1 is assumed if no version is specified. Content type and authorization headers do not need to be specified, since those are addressed elsewhere in the configuration.</td></tr>
<tr><td>DataBuck-etProperty</td><td>A string containing the variable that the response from the request will be returned in, if any. You can then reference this parameter from subsequent steps in the workflow.

  Tip: The response is stored as a serialized JObject. To make use of only a portion of the response data in your subsequent step, use JSON path syntax. For example, say you returned the data from a GET /Agents request in a variable called MyResponse and you wanted to reference the ClientMachine name for the orchestrator in a subsequent email message. To limit the data to the first result and only the ClientMachine name, in the email message you would enter the following:
<code>$(MyResponse.[0].ClientMachine)</code></td></tr>
<tr><td>Verb</td><td>A string indicating the HTTP verb for the type of request to perform. Supported values are:
DELETE
GET</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Name	Description
	Name / **Description** **Value** / **Description** • HEAD • OPTIONS • POST • PUT • TRACE UseBasicAuth: A Boolean indicating whether Basic authentication should be used for the request (True) or not (False). If *UseBasicAuth* is *False*, Windows authentication in the context of the Keyfactor Command application pool user will be used (see Create Active Directory Service Accounts for Keyfactor Command on page 2229 in the *Keyfactor Command Server Installation Guide*). BasicUsername: An array indicating the username information to use for authentication if *UseBasicAuth* is *True*. Supported methods to store credential information are: • Store the credential information in the Keyfactor secrets table. A Keyfactor secret is a user-defined username or password that is encrypted and stored securely in the Keyfactor Command database. • Load the credential information from a PAM provider. See PAM Providers on page 1439 and Privileged Access Management (PAM) on page 640 in the *Keyfactor Command Reference Guide* for more information. **Value** / **Description** SecretValue: A string containing the username defined for basic authentication (in DOMAIN\\username format). Parameters: An array indicating the parameters to supply for PAM authentication. These

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>will vary depending on the PAM provider.</td></tr>
<tr><td>Provider</td><td>A string indicating the ID of the PAM provider.
Use the GET /PamProviders method (see GET PAM Providers on page 1455) to retrieve a list of all the PAM providers to determine the ID.</td></tr>
</table>
For example, the username stored as a Keyfactor secret will look like:
<pre>{
   "SecretValue": "KEYEXAMPLE\svc_MyServiceName"
}</pre>
The username stored as a CyberArk PAM secret will look like (where the Provider value—1 in this example—is the Id value from GET PAM Providers on page 1455 and the Folder and Object reference the folder name and object name in the CyberArk safe):
<pre>{
   "Provider": "1",
   "Parameters":{
      "Folder":"MyFolderName",
      "Object":"MyWorkflowUsername"
   }
}</pre>
The username stored as a Delinea PAM secret will look like (where the Provider value—1 in this example—is the Id value from GET PAM Providers on page 1455 and the SecretId is the ID if the secret created in the Delinea secret server for this
</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>purpose):
<pre>{
   "Provider": "1",
   "Parameters":{
      "SecretId":"MyUsernameId"
   }
}</pre>
Due to its sensitive nature, this value is not returned in responses.</td></tr>
<tr><td>BasicPass-word</td><td>An array indicating the password information to use for authen-tication if UseBasicAuth is True. The syntax is the same as for BasicUsername.
Due to its sensitive nature, this value is not returned in responses.</td></tr>
<tr><td>URL</td><td>A string containing the URL for the request, including tokens, if desired. For a Keyfactor API request, this might look like:
<code>https://keyfactor.keyexample.com/KeyfactorAPI/Certificates?pq.queryString=CN%20-contains%20%22appsrvr14%22%20AND%20CertStorePath%20-ne%20NULL</code>
Or, with tokens:
<code>https://keyfactor.keyexample.com/KeyfactorAPI/Certificates/$(certid)</code>
Note: To prevent REST requests from being made to inappropriate locations by malicious users, configure a system environment variable of KEYFACTOR_BLOCKED_OUTBOUND_IPS on your Keyfactor Command server pointing to the IP address or range of addresses in CIDR format that you wish to block. Both IPv4 and IPv6 addresses are supported. More than one address or range may be specified in a comma-delimited list. For example:</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>192.168.12.0/24,192.168.14.22/24
When a REST request is made where the URL is either configured to a blocked IP address or resolves via DNS to a blocked IP address, the REST request will fail.</td></tr>
<tr><td>ContentType</td><td>A string indicating the content type for the request. Supported values are:
application/json</td></tr>
<tr><td>RequestContent</td><td>A string containing the body of the REST request, if needed. For a Keyfactor API request, this will vary depending on the request and might look like (for a PUT /Certificates/Metadata request):
<pre>{
   "Id": "$(certid)",
   "Metadata":{
      "RevocationComment": "$(cmnt)"
   }
}</pre>
Note: This example assumes you have a metadata field called RevocationComment.</td></tr>
</table>

Tip: Tokens (a.k.a. substitutable special text) may be used in the URL and request content fields. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can take the revocation comment entered when the revocation request is approved—$(cmnt)—and insert it into a custom metadata field in the certificate by doing a PUT /Certificates/Metadata request for the $(id).
</td></tr>
<tr><td>Signals</td><td>An array of objects containing data used at the point in the workflow step where the workflow needs to continue based on user input. These will vary depending on the type of workflow and the type of step (see ExtensionName). Possible RequireApproval values are:</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>RoleIds</td><td>An array of integers indicating the security roles whose members are allowed to approve the request.</td></tr>
<tr><td>SignalName</td><td>A string indicating the name of the signal. This value will vary depending on the workflow step. For the built-in Require Approval step, the SignalName is "ApprovalStatus".</td></tr>
</table>
Important: If all the security roles configured for a workflow step are deleted from Keyfactor Command, no users will be able to submit signals for workflow instances initiated with that workflow definition. To remedy this, update the workflow definition with one or more current security roles, re-publish it, and then restart any outstanding workflow instances.
</td></tr>
<tr><td>Conditions</td><td>An object containing conditions indicating whether the step should run (true) or not (false). Conditions may either have a static value of True or False or a token that will have a value of True or False at the time the step is run. More than one condition may be added. If multiple conditions are used in the same step, all conditions must have a value of True at the time the step is evaluated to be run in order for the step to run. If any single condition evaluates to False, the step will not run. Condition values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>Id</td><td>A string indicating the Keyfactor Command reference ID of the condition.</td></tr>
<tr><td>Value</td><td>A string indicating the value of the condition. This should be one of "true", "false", or a token that will be set to either "true" or "false" in an earlier step in the workflow (see <a>Adding or Modifying a Workflow Definition on page 210 in the Keyfactor Command Reference Guide for an example).</td></tr>
</table>
</td></tr>
<tr><td>Outputs</td><td>An array indicating the next step in the workflow. Possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>continue</td><td>A string indicating the UniqueName of the next workflow step in the chain. This value will be null for the final step in the chain.</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Name	Description
DraftVersion	An integer indicating the version number of the workflow definition. If this version number does not match the *PublishedVersion*, changes have been made to the workflow definition that have not yet been published.
PublishedVersion	An integer indicating the currently published version number of the workflow definition. For a newly created workflow, this value will be null.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.31.10 POST Workflow Definitions Definition ID Publish

The POST /Workflow/Definitions/{definitionid}/Publish method is used to mark the most recent version of the workflow definition with the specified GUID as the published, active, version. When a definition is published, all new or restarted workflow instances (see Workflow Instances on page 2070) will be able to use the updated version of the workflow. This method returns HTTP 200 OK on a success with details about the workflow definition.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
WorkflowDefinitions: *Modify*

Table 652: POST Workflow Definitions {definitionid} Publish Input Parameters

Name	In	Description
definitionId	Path	**Required**. A string indicating the Keyfactor Command reference GUID of the workflow definition to publish. Use the *GET /Workflow/Definitions* method (see GET Workflow Definitions on page 2013) to retrieve a list of all the workflow definitions to determine the GUID.

Table 653: POST Workflow Definitions {definitionid} Publish Response Body

Name	Description
Id	A string indicating the Keyfactor Command reference GUID of the workflow definition.
DisplayName	A string indicating the display name defined for the workflow definition.
Description	A string indicating the description for the workflow definition.
Key	A string indicating the reference key for the workflow definition. The type of information contained in this field will vary depending on the *WorkflowType*. If the *WorkflowType* is *Enrollment* or *Revocation*, this field will contain the Keyfactor Command reference ID for the certificate template.
KeyDisplayName	A string indicating the friendly name defined in Keyfactor Command for the certificate template.
IsPublished	A Boolean indicating whether the workflow definition has been published (true) or not (false). A workflow definition must be published to activate it. For a newly created workflow, this will be *false*.
WorkflowType	A string indicating the type of workflow definition. The currently supported types are: • Enrollment • Revocation
Steps	An array of objects indicating the steps in the workflow definition. The contents of each step will vary depending on the type of workflow and the type of step. For a newly created workflow, there will be no data in this value. Possible steps include:

Name	Description
Id	A string indicating the Keyfactor Command reference GUID of the workflow definition step.
DisplayName	A string indicating the display name for the step.
UniqueName	A string indicating the unique name for the step. This value must be unique among the steps in the particular workflow definition. It is intended to be used as a user-friendly reference ID.
ExtensionName	A string indicating the type of step. The currently supported types are: • **Email** Send an email message. This is a separate email message from those typically sent as part of a *Require Approval* step. You might send an email message as part of an enrollment request to notify approvers that a new request needs

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td>approval. The email messages can be customized to provide detailed information about, for example, the certificate request. • **PowerShell** Run PowerShell commands within the confines of the workflow to populate variables with information to pass back to the workflow. The PowerShell script contents are embedded within the step. This step does not call out to an external file. This provides a high level of security by greatly limiting the number of standard PowerShell cmdlets that can be executed by the workflow step. A small number of PowerShell cmdlets have been white listed to allow them to be included in workflow steps of this type, including: • Where-Object • ForEach-Object • Get-Command • **CustomPowerShell** Run a PowerShell script. The script contents are in a file placed in the ExtensionLibrary\Workflow directory or a subdirectory of it on the Keyfactor Command server under the install directory for Keyfactor Command. By default, this is: C:\Program Files\Keyfactor\Keyfactor Platform\ExtensionLibrary\Workflow The file must have an extension of .ps1. A sample PowerShell script is provided in the Workflow directory (CustomPowershellExample.ps1). • **RequireApproval** Require approval for a workflow step before the step can be completed. The require approval step applies to certificate enrollments, renewals, and revocations and can require approval from just one approver or multiple approvers. The workflow will be suspended at this point until the correct number of approvals from users with the correct security roles is received or until one deny is received before continuing to the next step. As part of this step, an email message is sent indicating whether the step was approved or denied—typically to the requester. This step does not include logic to send an email initiating the approval process (letting users know something needs approval). Use an *Email* type step for this. **Important:** Workflows are not supported with CA delegation when they contain steps that require approval. For more information, see the CA configuration Authorization Methods Tab on page 322 in the *Keyfactor Command Reference Guide*.</td></tr></table>

Name	Description
	<table><tr><th>Name</th><th>Description</th></tr><tr><td></td><td> **Note:** The users that you send email to initiating the approval process must be members of a security role that is allowed to submit signals (approve/deny) for the workflow in order to approve or deny the request. **Tip:** The workflow builder does not include a step to send a notification to the requester of a certificate once the certificate is issued by the CA (as opposed to approved in Keyfactor Command). Use the issued alerts for this (see Issued Request Alert Operations on page 170 in the *Keyfactor Command Reference Guide*). • **RESTRequest** Run a REST (API) request. The REST request contents are embedded within the step. It does not call out to an external file. • **EnrollmentAgent** On an enrollment (either CSR or PFX), create a resigned CSR to prepare an updated enrollment request for delivery to a Microsoft CA after a previous step in the workflow has been used to update either the SANs in the initial request, subject (DN) in the initial request or both. This step must be placed later in the workflow than the step(s) to modify the SANs and/or subject. The SANs and subject may be modified with either of the PowerShell step types or a custom step type. The step creates a new CSR using the same public key as the original CSR using the updated SAN and/or subject values. It signs the new CSR with the certificate provided in the step's configuration. For this type of step you will need an enrollment agent certificate available as a PKCS#12 (.PFX) file with included private key to import into Keyfactor Command. This can be a user certificate or a computer certificate (e.g. generated from a copy of the "Enrollment Agent" template or the "Enrollment Agent (Computer)" template) and must have a Certificate Request Agent EKU. Note that the built-in "Enrollment Agent" and "Enrollment Agent (Computer)" templates do not allow private keys to be exported by default. You will need a template that allows private key export or will need to manually override private key export to create a certificate with an exportable private key in order to create a PKCS#12 (.PFX) file. **Important:** This step applies to Microsoft CAs only. If this step is added to workflow for requests directed to an EJBCA CA, it will fail on enrollment. Note that EJBCA supports submission of updated SAN or subject details as part of standard functionality.</td></tr></table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>

SubjectFormatter
On an enrollment done through the Keyfactor Windows Enrollment Gateway using a client-side template configured with the Build from this Active Directory information option on the template, this workflow step handles formatting the incoming subject, SANs, and/or SID in the certificate request appropriately such that the enrollment will complete successfully with the target CA and Keyfactor Command template, which is not configured to build from AD. Any Keyfactor Windows Enrollment Gateway using a client-side template configured with the subject as Build from this Active Directory information must be configured with a workflow step of this type on the Keyfactor Command template that has been mapped in the gateway to that template in order to complete an enrollment through the gateway. There are no configuration parameters for the step.

  Important: The template in Keyfactor Command that is mapped to the client-side template configured to build the subject from Active Directory also needs to be configured with three enrollment fields to support handling the incoming subject, SANs, and/or SID. For more information about configuring this, see the Keyfactor Windows Enrollment Gateway Installation and Configuration Guide.
EnrollStep
Enroll for a certificate through Keyfactor Command. The enroll step must always fall as the last step in the workflow, immediately following the EndNOOP step.
NOOPStep
An entry or exit step in which no operation occurs. Steps of this type indicate the start and end of the workflow.
RevokeStep
Revoke a certificate through Keyfactor Command. The revoke step must always fall as the last step in the workflow, immediately following the EndNOOP step.

 Tip: For steps that send email messages, the SMTP settings and sender information come from the standard Keyfactor Command SMTP configuration (see SMTP on page 1814) and are not configured individually in the workflow steps.
</td></tr>
<tr><td>Enabled</td><td>A Boolean indicating whether the step is enabled to run (true) or not (false).</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>ConfigurationParameters</td><td>
An array containing the configuration parameters for the workflow definition step. These will vary depending on the type of workflow and the type of step (see ExtensionName).

Note: There are no ConfigurationParameters for steps of type SubjectFormatter, EnrollStep, NOOPStep, or RevokeStep.

Possible CustomPowerShell parameters include:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>ScriptParameters</td><td>An array of key/value pair strings defining any parameters to be used in the PowerShell script.</td></tr>
<tr><td>ScriptName</td><td>The path and filename for the script to execute. The script needs to be in the ExtensionLibrary\Workflow directory or a subdirectory of it on the Keyfactor Command server under the install directory. By default, this is:
<code>C:\Program Files\Keyfactor\Keyfactor Platform\ExtensionLibrary\Workflow</code>
The file must have an extension of .ps1.
A sample PowerShell script is provided in the Workflow directory (CustomPowershellExample.ps1).</td></tr>
</table>
Tip: Tokens (a.k.a. substitutable special text) may be used in the script parameter value field. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can take the revocation comment entered when the revocation request is approved—$(cmnt)—and append additional data to it using PowerShell.

Possible Email parameters include:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>Subject</td><td>A string indicating the subject line for the email message that will be delivered when the workflow definition step is executed.</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Name	Description
	Name / **Description**

Name

Description

Value	Description
Message	A string indicating the email message that will be delivered when the workflow definition step is executed. The email message is made up of regular text and tokens. If desired, you can format the message body using HTML. For example, for an enrollment pending request notification: "Hello,\n\nA certificate using the $(template) template was requested by $(requester:displayname) from $(CA) on $(subdate). The certificate details include:\n\n<table>\n<tr><th>Certificate Details</th><th>Metadata</th></tr>\n<tr><td>CN: $(request:cn)</td><td>App Owner First Name: $(metadata:AppOwnerFirstName)</td></tr>\n<tr><td>DN: $(request:dn)</td><td>App Owner Last Name: $(metadata:AppOwnerLastName)</td></tr>\n<tr><td>SANs: $(sans)</td><td>App Owner Email Address: $(metadata:AppOwnerEmailAddress)</td></tr>\n<tr><td> </td><td>Business Critical: $(metadata:BusinessCritical)</td></tr>\n\nPlease review this request and issue the certificate as appropriate by going here:\n\n$(reviewlink)\n\nThanks!\n\nYour Certificate Management Tool\n" See Table 13: Tokens for Workflow Definitions in the *Keyfactor Command Reference Guide* for a complete list of available tokens.
Recipients	An array of strings containing the recipients for the workflow definition email. Each email message can have multiple recipients. You can use specific email addresses and/or use tokens to replace an email address variable with actual email addresses at processing time. Available email tokens include: • $(requester:mail) The certificate requester, based on a lookup in Active Directory of the email address associated with the requester on the certificate. • Your custom email-based metadata field, which would be specified similarly to $(metadata:AppOwnerEmailAddress).

Tip: Tokens (a.k.a. substitutable special text) may be used in the subject line,

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
message and email recipient fields. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can select $(requester) in the workflow definition for an enrollment request and the email message will contain the specific certificate requester name instead of the variable $(requester).

Possible PowerShell parameters include:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>ScriptParameters</td><td>An array of key/value pair strings defining any parameters to be used in the PowerShell script. The key is the name of a custom parameter defined by you and the value is the initial value that should be set for that parameter before the PowerShell is executed, if any. Tokens are supported in the value.</td></tr>
<tr><td>ScriptContent</td><td>A string containing the PowerShell commands to execute. This should be the actual contents of the PowerShell script (the PowerShell commands and supporting components), not a path and filename to an external file.</td></tr>
</table>
Tip: Tokens (a.k.a. substitutable special text) may be used in the script parameter value field. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can take the revocation comment entered when the revocation request is approved—$(cmnt)—and append additional data to it using PowerShell.

Possible RequireApproval parameters include:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>MinimumApprovals</td><td>In integer indicating the minimum number of users who must approve the request to allow the request to complete.</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Name	Description
	Name / **Description**

Value	Description
DenialEmailSubject	A string indicating the subject line for the email message that will be delivered if the request is denied.
DenialEmailMessage	A string indicating the email message that will be delivered if the request is denied. The email message is made up of regular text and tokens. If desired, you can format the message body using HTML. See Table 13: Tokens for Workflow Definitions in the *Keyfactor Command Reference Guide* for a complete list of available tokens.
DenialEmailRecipients	An array of strings containing the recipients for the denial email. Each email message can have multiple recipients. You can use specific email addresses and/or use tokens to replace an email address variable with actual email addresses at processing time. Available email tokens include: • $(requester:mail) The certificate requester, based on a lookup in Active Directory of the email address associated with the requester on the certificate. • Your custom email-based metadata field, which would be specified similarly to $(metadata:AppOwnerEmailAddress).
ApprovalEmailSubject	A string indicating the subject line for the email message that will be delivered if the request is approved.
ApprovalEmailMessage	A string indicating the email message that will be delivered if the request is approved. The email message is made up of regular text and tokens. If desired, you can format the message body using HTML.

Name	Description
	Name / **Description**

Value	Description
	See Table 13: Tokens for Workflow Definitions in the *Keyfactor Command Reference Guide* for a complete list of available tokens.
ApprovalEmailRecipients	An array of strings containing the recipients for the approval email. Each email message can have multiple recipients. You can use specific email addresses and/or use tokens to replace an email address variable with actual email addresses at processing time. Available email tokens include: • $(requester:mail) The certificate requester, based on a lookup in Active Directory of the email address associated with the requester on the certificate. • Your custom email-based metadata field, which would be specified similarly to $(metadata:AppOwnerEmailAddress).

Tip: Tokens (a.k.a. substitutable special text) may be used in the subject line, message and email recipient fields. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can select $(requester) in the workflow definition for an enrollment request and the email message will contain the specific certificate requester name instead of the variable $(requester).

Possible **RestRequest** parameters include:

Value	Description
Headers	An array of key/value pair strings containing the header information for the request. The key is the name of the specific request header (for Keyfactor API request headers, see Table 63: Common Request Headers and the specific documentation for

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>each endpoint) and the value is the value that should be set for that header. For a Keyfactor API request, this might look like:

<pre>"Headers": {
   "x-keyfactor-requested-with": [
      "APIClient"
   ],
   "x-keyfactor-api-version": [
      "2"
   ]
}</pre>
  Tip: For a Keyfactor API request, version 1 is assumed if no version is specified. Content type and authorization headers do not need to be specified, since those are addressed elsewhere in the configuration.</td></tr>
<tr><td>DataBuck-etProperty</td><td>A string containing the variable that the response from the request will be returned in, if any. You can then reference this parameter from subsequent steps in the workflow.

  Tip: The response is stored as a serialized JObject. To make use of only a portion of the response data in your subsequent step, use JSON path syntax. For example, say you returned the data from a GET /Agents request in a variable called MyResponse and you wanted to reference the ClientMachine name for the orchestrator in a subsequent email message. To limit the data to the first result and only the ClientMachine name, in the email message you would enter the following:
<code>$(MyResponse.[0].ClientMachine)</code></td></tr>
<tr><td>Verb</td><td>A string indicating the HTTP verb for the type of request to perform. Supported values are:
DELETE
GET</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>

- HEAD
- OPTIONS
- POST
- PUT
- TRACE

</td></tr>
<tr><td>UseBasicAuth</td><td>A Boolean indicating whether Basic authentication should be used for the request (True) or not (False).
If UseBasicAuth is False, Windows authentication in the context of the Keyfactor Command application pool user will be used (see Create Active Directory Service Accounts for Keyfactor Command on page 2229 in the Keyfactor Command Server Installation Guide).</td></tr>
<tr><td>BasicUsername</td><td>An array indicating the username information to use for authentication if UseBasicAuth is True.
Supported methods to store credential information are:

Store the credential information in the Keyfactor secrets table.
A Keyfactor secret is a user-defined username or password that is encrypted and stored securely in the Keyfactor Command database.
Load the credential information from a PAM provider.
See PAM Providers on page 1439 and Privileged Access Management (PAM) on page 640 in the Keyfactor Command Reference Guide for more information.

<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>SecretValue</td><td>A string containing the username defined for basic authentication (in DOMAIN\\username format).</td></tr>
<tr><td>Parameters</td><td>An array indicating the parameters to supply for PAM authentication. These</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Name	Description

	Name / **Description**
	Value / **Description**
	Value / **Description**
	will vary depending on the PAM provider.
	Provider — A string indicating the ID of the PAM provider. Use the *GET /PamProviders* method (see GET PAM Providers on page 1455) to retrieve a list of all the PAM providers to determine the ID.
	For example, the username stored as a Keyfactor secret will look like:
	`{ "SecretValue": "KEYEXAMPLE\svc_MyServiceName" }`
	The username stored as a CyberArk PAM secret will look like (where the Provider value—1 in this example—is the Id value from GET PAM Providers on page 1455 and the Folder and Object reference the folder name and object name in the CyberArk safe):
	`{ "Provider": "1", "Parameters":{ "Folder":"MyFolderName", "Object":"MyWorkflowUsername" } }`
	The username stored as a Delinea PAM secret will look like (where the Provider value—1 in this example—is the Id value from GET PAM Providers on page 1455 and the SecretId is the ID if the secret created in the Delinea secret server for this

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>purpose):
<pre>{
   "Provider": "1",
   "Parameters":{
      "SecretId":"MyUsernameId"
   }
}</pre>
Due to its sensitive nature, this value is not returned in responses.</td></tr>
<tr><td>BasicPass-word</td><td>An array indicating the password information to use for authen-tication if UseBasicAuth is True. The syntax is the same as for BasicUsername.
Due to its sensitive nature, this value is not returned in responses.</td></tr>
<tr><td>URL</td><td>A string containing the URL for the request, including tokens, if desired. For a Keyfactor API request, this might look like:
<code>https://keyfactor.keyexample.com/KeyfactorAPI/Certificates?pq.queryString=CN%20-contains%20%22appsrvr14%22%20AND%20CertStorePath%20-ne%20NULL</code>
Or, with tokens:
<code>https://keyfactor.keyexample.com/KeyfactorAPI/Certificates/$(certid)</code>
Note: To prevent REST requests from being made to inappropriate locations by malicious users, configure a system environment variable of KEYFACTOR_BLOCKED_OUTBOUND_IPS on your Keyfactor Command server pointing to the IP address or range of addresses in CIDR format that you wish to block. Both IPv4 and IPv6 addresses are supported. More than one address or range may be specified in a comma-delimited list. For example:</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>192.168.12.0/24,192.168.14.22/24
When a REST request is made where the URL is either configured to a blocked IP address or resolves via DNS to a blocked IP address, the REST request will fail.</td></tr>
<tr><td>ContentType</td><td>A string indicating the content type for the request. Supported values are:
application/json</td></tr>
<tr><td>RequestContent</td><td>A string containing the body of the REST request, if needed. For a Keyfactor API request, this will vary depending on the request and might look like (for a PUT /Certificates/Metadata request):
<pre>{
   "Id": "$(certid)",
   "Metadata":{
      "RevocationComment": "$(cmnt)"
   }
}</pre>
Note: This example assumes you have a metadata field called RevocationComment.</td></tr>
</table>

Tip: Tokens (a.k.a. substitutable special text) may be used in the URL and request content fields. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can take the revocation comment entered when the revocation request is approved—$(cmnt)—and insert it into a custom metadata field in the certificate by doing a PUT /Certificates/Metadata request for the $(id).
</td></tr>
<tr><td>Signals</td><td>An array of objects containing data used at the point in the workflow step where the workflow needs to continue based on user input. These will vary depending on the type of workflow and the type of step (see ExtensionName). Possible RequireApproval values are:</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>RoleIds</td><td>An array of integers indicating the security roles whose members are allowed to approve the request.</td></tr>
<tr><td>SignalName</td><td>A string indicating the name of the signal. This value will vary depending on the workflow step. For the built-in Require Approval step, the SignalName is "ApprovalStatus".</td></tr>
</table>
Important: If all the security roles configured for a workflow step are deleted from Keyfactor Command, no users will be able to submit signals for workflow instances initiated with that workflow definition. To remedy this, update the workflow definition with one or more current security roles, re-publish it, and then restart any outstanding workflow instances.
</td></tr>
<tr><td>Conditions</td><td>An object containing conditions indicating whether the step should run (true) or not (false). Conditions may either have a static value of True or False or a token that will have a value of True or False at the time the step is run. More than one condition may be added. If multiple conditions are used in the same step, all conditions must have a value of True at the time the step is evaluated to be run in order for the step to run. If any single condition evaluates to False, the step will not run. Condition values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>Id</td><td>A string indicating the Keyfactor Command reference ID of the condition.</td></tr>
<tr><td>Value</td><td>A string indicating the value of the condition. This should be one of "true", "false", or a token that will be set to either "true" or "false" in an earlier step in the workflow (see <a>Adding or Modifying a Workflow Definition on page 210 in the Keyfactor Command Reference Guide for an example).</td></tr>
</table>
</td></tr>
<tr><td>Outputs</td><td>An array indicating the next step in the workflow. Possible values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>continue</td><td>A string indicating the UniqueName of the next workflow step in the chain. This value will be null for the final step in the chain.</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Name	Description
DraftVersion	An integer indicating the version number of the workflow definition. If this version number does not match the *PublishedVersion*, changes have been made to the workflow definition that have not yet been published.
PublishedVersion	An integer indicating the currently published version number of the workflow definition. For a newly created workflow, this value will be null.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon () at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.32 Workflow Instances

The Workflow Instances component of the Keyfactor API includes methods necessary to programmatically retrieve, restart, delete and submit data into workflow instances.

Table 654: Workflow Instances Endpoints

Endpoint	Method	Description	Link
/{instanceId}	DELETE	Delete the workflow instance with he specified GUID.	DELETE Workflow Instances Instance Id on the next page
/{instanceId}	GET	Retrieve the workflow instance with the specified GUID.	GET Workflow Instances Instance ID on the next page
/	GET	Retrieve a list of the workflow instances.	GET Workflow Instances on page 2092
/My	GET	Retrieve the workflow instances created by the user making the API request.	GET Workflow Instances My on page 2095
/AssignedToMe	GET	Retrieve the workflow instances assigned to the user making the API request.	GET Workflow Instances AssignedToMe on page 2098
/{instanceId}/Stop	POST	Rejects a workflow instance, preventing it from continuing.	POST Workflow Instances Instance Id Stop on page 2102
/{instanceId}/Signals	POST	Input data to the workflow instance with the specified GUID.	POST Workflow Instances Instance ID Signals on page 2102
/{instanceId}/Restart	POST	Restart the specified workflow instance after a failure.	POST Workflow Instances Instance Id Restart on page 2105

3.2.32.1 DELETE Workflow Instances Instance Id

The DELETE /Workflow/Instances/{instanceId} method is used to delete the workflow instance with the specified GUID. This endpoint returns 204 with no content upon success.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
WorkflowInstances: *Manage*

Table 655: DELETE Workflow Instances {instanceId} Input Parameters

Name	In	Description
instanceId	Path	**Required**. A string indicating the Keyfactor Command reference GUID of the workflow instance to delete. Use the *GET /Workflow/Instances* method (see GET Workflow Instances on page 2092) to retrieve a list of all the workflow instances to determine the GUID.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.32.2 GET Workflow Instances Instance ID

The GET /Workflow/Instances/{instanceId} method is used to retrieve the initiated workflow with the specified instance GUID. Both in progress and completed workflows will be returned. This method returns HTTP 200 OK on a success with details about the workflow instance.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
WorkflowInstances: *ReadAll* OR
WorkflowInstances: *ReadAssignedToMe* OR
WorkflowInstances: *ReadMy*

Users with *ReadMy* or *ReadAssignedToMe* will only be able to retrieve the workflow instances created by them (*ReadMy*) or assigned to them (*ReadAssignedToMe*) unless they also have *ReadAll*.

Table 656: GET Workflow Instances {instanceId} Input Parameters

Name	In	Description
instanceId	Path	**Required**. A string indicating the Keyfactor Command reference GUID of the workflow instance to retrieve. Use the *GET /Workflow/Instances* method (see GET Workflow Instances on page 2092) to retrieve a list of all the workflow instances to determine the GUID. Note that the **integer** workflow IDs (returned with *GET /Workflow/Instances/{instanceId}* cannot be used with the API, only the GUID from *GET /Workflow/Instances* is valid.

Table 657: GET Workflow Instances {instanceId} Response Data

Name	Description
Id	A string indicating the Keyfactor Command reference GUID of the workflow instance.
Status	A string indicating the current status of the workflow instance. The possible statuses are: • CanceledForRestart • Complete • Failed • Rejected • Running • Suspended
CurrentStepID	A string indicating the Keyfactor Command reference GUID of the workflow instance step.
StatusMessage	A string indicating the current status message for the workflow instance. Possible status messages vary and may include: • Access is denied • Awaiting *#* more approval(s) from approval roles. • Either the credentials are invalid, or the CA on [*CA hostname*] is not running • Issued • Issued. The private key was successfully retained. • Post-process Failed: *[Message indicating reason for failure generally from the CA*] • Pre-process failed: *[Message indicating details of the failure*] • Revoked • Step 'Keyfactor-Enroll' failed: *[Message indicating details of the failure*] • Step 'Keyfactor-Revoke' failed:*[Message indicating details of the failure*] • Step [*custom step name*] failed: [*Message indicating details of the failure*] • Taken Under Submission. The certificate template requires manager approval, and is marked as pending. • Workflow rejected by user with Id *#*.
Signals	An object containing the data used at the point in the workflow step where the workflow needs to continue based on user input. These will vary depending on the type of workflow and the type of step. Possible **RequireApproval** values are: **Value** / **Description** SignalName — A string indicating the name of the signal. For a RequireApproval step, this is *ApprovalStatus*. StepSignalId — A string indicating the Keyfactor Command reference GUID of the signal in

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>the step.</td></tr>
<tr><td>SignalReceived</td><td>A Boolean indicating whether a signal (input) has been received from at least one end user (true) or not (false).
For a RequireApproval workflow that requires approval from more than one user, the SignalReceived may be true while the workflow instance still has a Suspended status indicating further input is needed.</td></tr>
</table>
</td></tr>
<tr><td>Definition</td><td>An array containing the workflow definition. Workflow definition data includes:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Id</td><td>A string indicating the Keyfactor Command reference GUID of the workflow definition.</td></tr>
<tr><td>DisplayName</td><td>A string indicating the display name defined for the workflow definition.</td></tr>
<tr><td>Version</td><td>An integer indicating the version number of the workflow definition.</td></tr>
<tr><td>WorkflowType</td><td>A string indicating the type of workflow definition. The currently supported types are:
• Enrollment
• Revocation</td></tr>
</table>
</td></tr>
<tr><td>CurrentStepDisplayName</td><td>A string indicating the display name defined for the workflow instance step.</td></tr>
<tr><td>CurrentStepUniqueName</td><td>A string indicating the unique name defined for the workflow instance step. This value is unique among the steps in a particular workflow definition. It is intended to be used as a user-friendly reference ID.</td></tr>
<tr><td>Title</td><td>A string indicating a description for the action taking place in the step, made up of the InitiatingUserName (DOMAIN\\username) followed by an indication of the type of action and a specific message about the action. For example:
"KEYEXAMPLE\\jsmith is enrolling for a certificate with CN=appssrvr14.keyexample.com."
Or
"KEYEXAMPLE\\jsmith is revoking certificate with CN=appsrvr12.keyexample.com."</td></tr>
<tr><td>LastModified</td><td>A string indicating the date and time on which the initiated instance was last updated. The instance is updated each time a step in the workflow is completed, when signals are received for a step that accepts signals (e.g. a requires approval step), or when an instance is stopped or restarted.</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>StartDate</td><td>A string indicating the date and time when the instance was initiated.</td></tr>
<tr><td>InitialData</td><td>An array containing the data included in the workflow instance when the workflow was initiated. Initial workflow instance data includes:
<table>
<tr><th>Name</th><th>Operation Type</th><th>Description</th></tr>
<tr><td>CertificateAuthority</td><td>Enrollment and Revocation</td><td>A string indicating the certificate authority that will be used to enroll against, for enrollment requests, or that issued the certificate, for revocation requests in hostname\logical name format.</td></tr>
<tr><td>CertificateId</td><td>Revocation</td><td>An integer indicating the Keyfactor Command reference ID for the certificate.</td></tr>
<tr><td>SerialNumberString</td><td>Revocation</td><td>A string indicating the serial number of the certificate being revoked.</td></tr>
<tr><td>Thumbprint</td><td>Revocation</td><td>A string indicating the thumbprint of the certificate being revoked.</td></tr>
<tr><td>RevokeCode</td><td>Revocation</td><td>An integer containing the specific reason that the certificate is being revoked. Available values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>-1</td><td>Remove from Hold</td></tr>
<tr><td>0</td><td>Unspecified</td></tr>
<tr><td>1</td><td>Key Compromised</td></tr>
<tr><td>2</td><td>CA Compromised</td></tr>
<tr><td>3</td><td>Affiliation Changed</td></tr>
<tr><td>4</td><td>Superseded</td></tr>
<tr><td>5</td><td>Cessation of Operation</td></tr>
</table></td></tr>
</table></td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Oper-ation Type</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>6</td><td>Certificate Hold</td></tr>
<tr><td>7</td><td>Remove from CRL. Only valid in the case that a cert is already on a CRL in a manner that it can be removed, such as Certificate Hold</td></tr>
</table>
The default is Unspecified.
</td></tr>
<tr><td>EffectiveDate</td><td>Revoc-ation</td><td>A string containing the date and time when the certificate will be revoked.</td></tr>
<tr><td>Comment</td><td>Revoc-ation</td><td>A string containing a freeform reason or comment on why the certificate is being revoked.</td></tr>
<tr><td>Delegate</td><td>Revoc-ation</td><td>A Boolean indicating whether delegation is enabled for the certificate authority that issued the certificate (true) or not (false).</td></tr>
<tr><td>OperationStart</td><td>Revoc-ation</td><td>A string indicating the time at which the revocation work-flow was initiated.</td></tr>
<tr><td>Template</td><td>Enroll-ment</td><td>A string indicating the certificate template short name used for the enrollment request.</td></tr>
<tr><td>IncludeChain</td><td>Enroll-ment</td><td>A Boolean indicating whether to include the certificate chain in the enrollment response (true) or not (false).</td></tr>
<tr><td>SANs</td><td>Enroll-ment</td><td>An array of key/value pairs indicating the subject alter-native names (SANs) for the certificate requested in the enrollment. Possible values for the key are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>rfc822</td><td>RFC 822 Name</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Oper-ation Type</th><th>Description</th></tr>
<tr><td></td><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>dns</td><td>DNS Name</td></tr>
<tr><td>directory</td><td>Directory Name</td></tr>
<tr><td>uri</td><td>Uniform Resource Identifier</td></tr>
<tr><td>ip4</td><td>IP v4 Address</td></tr>
<tr><td>ip6</td><td>IP v6 Address</td></tr>
<tr><td>registeredid</td><td>Registered ID (an OID)</td></tr>
<tr><td>ms_ntprincipalname</td><td>MS_NTPrincipalName (a string)</td></tr>
<tr><td>ms_ntdsreplication</td><td>MS_NTDSReplication (a GUID)</td></tr>
</table>
For example:
<pre>
"SANs": {
   "dns": [
      "dnssan1.keyexample.com",
      "dnssan2.keyexample.com",
      "dnssan3.keyexample.com"
   ],
   "ip4": [
      "192.168.2.73"
   ]
}
</pre>
</td></tr>
<tr><td>AdditionalAttributes</td><td>Enroll-ment</td><td>An array of key/value pairs indicating values for any custom enrollment fields set on the certificate template to supply custom request attributes to the CA during the enrollment process.</td></tr>
<tr><td>Metadata</td><td>Enroll-ment</td><td>An array of key/value pairs indicating values for the metadata fields that will be associated with the certificate once it is in Keyfactor Command. The key is the field name</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Operation Type</th><th>Description</th></tr>
<tr><td></td><td></td><td>and the value is the value for the field.</td></tr>
<tr><td>Format</td><td>Enrollment</td><td>A string indicating the desired output format for the certificate. A value of STORE indicates that the certificate is intended to be delivered into one or more certificate stores.</td></tr>
<tr><td>CustomName</td><td>Enrollment</td><td>A string indicating a custom friendly name for the certificate.</td></tr>
<tr><td>Subject</td><td>Enrollment</td><td>A string containing the subject name of the requested certificate using X.500 format.</td></tr>
<tr><td>RenewalCertificate</td><td>Enrollment</td><td>An array containing the certificate information for the certificate that is being renewed. Certificate data includes:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Certificate</td><td>An array containing a key value pair referencing the certificate being renewed in the following format:
<pre>{
"RawData":"[PEM-encoded certificate string]"
}</pre></td></tr>
<tr><td>CertificateId</td><td>An integer containing the Keyfactor Command reference ID of the certificate being renewed.</td></tr>
</table>
Note: This field is only populated for enrollments that are generated by requesting a certificate renewal (see Renew on page 61 in the Keyfactor Command Reference Guide and POST Enrollment Renew on page 1355).</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Oper-ation Type</th><th>Description</th></tr>
<tr><td>Stores</td><td>Enroll-ment</td><td>An object containing a comma delimited set of arrays indic-ating the certificate stores to which the certificate should be distributed. Store details include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>StoreId</td><td>An array of GUIDs indicating the certificate store(s) to which the certificate should be deployed.
Use the GET /CertificateStores method (see GET Certificate Stores on page 1100) with a query of "Approved -eq true" to retrieve a list of all your approved certi-ficate stores to determine the GUID(s) of the store(s).</td></tr>
<tr><td>Alias</td><td>The alias of the certificate upon entry into the store. The format of and requirement for this varies depending on the certificate store type and whether the Overwrite flag is selected. See PFX Enrollment on page 132 in the Keyfactor Command Refer-ence Guide for more information.</td></tr>
<tr><td>Over-write</td><td>A Boolean that sets whether a certificate in the store with the Alias provided should be overwritten with the new certificate (true) or not (false). The default is false.
Use the GET /Certificates/Locations/{id} method (see GET Certificates Locations ID on page 940) to retrieve a list of the loca-tions an existing certificate is in to determine the alias used for the certificate in the certificate store.</td></tr>
<tr><td>Prop-erties</td><td>An array of key/value pairs for the unique</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Name	Description

	Name / **Oper-ation Type** / **Description**
	Name / **Description**
	parameters defined for the certificate store type that need to be populated for the certificate. The *key* is the name of the specific parameter from the certificate store type definition as returned in the JobProperties on the store type using the *GET CertificateStoreTypes* method and the *value* is the value that should be set for that parameter on the certificate in the certificate store. For example, for NetScaler, the key name that is optionally used to associate the certificate with a virtual server is *NetscalerVserver* and is returned by *GET CertificateStoreTypes* like so:
	`"JobProperties": [ "NetscalerVserver" ]`
	It can be seen in the Keyfactor Command Management Portal when editing the certificate store type in the field for *Management Job Custom Fields*.
	The setting is referenced using the following format:
	`"Properties": {"NetscalerVserver":"MyVirtualServerName"}`
	Note: The only built-in certificate store type that makes use of properties that can be set on a certificate-by-certificate basis in the store is NetScaler. You may have custom certificate store types that make use of this functionality.

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Operation Type</th><th>Description</th></tr>
<tr><td>ManagementJobTime</td><td>Enrollment</td><td>An array indicating the schedule for the management job to add the certificate to the certificate store(s). Possible management job time values include:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Immediate</td><td>A Boolean that indicates a job scheduled to run immediately (true) or not (false).

Tip: In some instances, jobs initially scheduled as Immediate will appear on a GET as null.</td></tr>
<tr><td>ExactlyOnce</td><td>A dictionary that indicates a job scheduled to run at the time specified with the parameter:
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Time</td><td>The date and time to next run the job. The date and time should be given using the ISO 8601 UTC time format YYYY-MM-DDTHH:mm:ss.000Z (e.g. 2021-05-19T16:23:01Z).</td></tr>
</table>
For example, exactly once at 11:45 am:
<pre>"ExactlyOnce": {
   "Time": "2022-02-27T11:45:00Z"
}</pre></td></tr>
</table></td></tr>
</table></td></tr>
</table>

3.2.32.3 GET Workflow Instances

The GET /Workflow/Instances method is used to retrieve the list of workflows that have been initiated. Both in progress and completed workflows are included. This method returns HTTP 200 OK on a success with details about the workflow instances.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: WorkflowInstances: *ReadAll*

Table 658: GET Workflow Instances Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Using the Workflow Instances Search Feature on page 282. The query fields supported for this endpoint are: • *DefinitionId* (workflow definition ID) • *Id* (workflow instance GUID) • *InitiatingUserName* (DOMAIN\\username) • *LastModified* • *ReferenceId* (workflow instance integer ID) • *StartDate* • *Status* • *Title* • *WorkflowType*
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *CurrentStepDisplayName*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 659: GET Workflow Instances Response Data

Name	Description
Id	A string indicating the Keyfactor Command reference GUID of the workflow instance.
Status	A string indicating the current status of the workflow instance. The possible statuses are: • CanceledForRestart • Complete • Failed • Rejected • Running • Suspended
CurrentStepID	A string indicating the Keyfactor Command reference GUID of the workflow instance step.
StatusMessage	A string indicating the current status message for the workflow instance. Possible status messages vary and may include: • Access is denied • Awaiting *#* more approval(s) from approval roles. • Either the credentials are invalid, or the CA on [*CA hostname*] is not running • Issued • Issued. The private key was successfully retained. • Post-process Failed: *[Message indicating reason for failure generally from the CA*] • Pre-process failed: *[Message indicating details of the failure*] • Revoked • Step 'Keyfactor-Enroll' failed: *[Message indicating details of the failure*] • Step 'Keyfactor-Revoke' failed:*[Message indicating details of the failure*] • Step [*custom step name*] failed: [*Message indicating details of the failure*] • Taken Under Submission. The certificate template requires manager approval, and is marked as pending. • Workflow rejected by user with Id *#*.
Definition	An array containing the workflow definition. Workflow definition data includes: **Name** / **Description** Id — A string indicating the Keyfactor Command reference GUID of the workflow definition. DisplayName — A string indicating the display name defined for the workflow definition.

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td>Version</td><td>An integer indicating the version number of the workflow definition.</td></tr>
<tr><td>WorkflowType</td><td>A string indicating the type of workflow definition. The currently supported types are:
Enrollment
Revocation</td></tr>
</table>
</td></tr>
<tr><td>CurrentStepDisplayName</td><td>A string indicating the display name defined for the workflow instance step.</td></tr>
<tr><td>CurrentStepUniqueName</td><td>A string indicating the unique name defined for the workflow instance step. This value is unique among the steps in a particular workflow definition. It is intended to be used as a user-friendly reference ID.</td></tr>
<tr><td>Title</td><td>A string indicating a description for the action taking place in the step, made up of the InitiatingUserName (DOMAIN\\username) followed by an indication of the type of action and a specific message about the action. For example:
"KEYEXAMPLE\\jsmith is enrolling for a certificate with CN=apps-srvr14.keyexample.com."
Or
"KEYEXAMPLE\\jsmith is revoking certificate with CN=apps-srvr12.keyexample.com."</td></tr>
<tr><td>LastModified</td><td>A string indicating the date and time on which the initiated instance was last updated. The instance is updated each time a step in the workflow is completed, when signals are received for a step that accepts signals (e.g. a requires approval step), or when an instance is stopped or restarted.</td></tr>
<tr><td>StartDate</td><td>A string indicating the date and time when the instance was initiated.</td></tr>
<tr><td>ReferenceId</td><td>A integer indicating the Keyfactor Command reference ID for the workflow instance.</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.32.4 GET Workflow Instances My

The GET /Workflow/Instances/My method is used to retrieve the list of initiated workflows created by the user making the API request—as a result of enrolling for a certificate, for example, or revoking a certificate. This method returns HTTP 200 OK on a success with details about the workflow instances.

Note: If a workflow instance is initiated for a workflow definition that has more than one step requiring input (signals), a user can only provide that input (e.g. approve or deny a require approval request) at the step in the workflow instance where the workflow instance was suspended pending input. The user cannot jump ahead and provide input for future steps in the workflow that have not yet occurred.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
WorkflowInstances: *ReadAll* OR
WorkflowInstances: *ReadMy*

Table 660: GET Workflow Instances My Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Using the Workflow Instances Search Feature on page 282. The query fields supported for this endpoint are: • *DefinitionId* (workflow definition ID) • *Id* (workflow instance GUID) • *InitiatingUserName* (DOMAIN\\username) • *LastModified* • *ReferenceId* (workflow instance integer ID) • *StartDate* • *Status* • *Title* • *WorkflowType*
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *Id*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 661: GET Workflow Instances My Response Data

Name	Description
Id	A string indicating the Keyfactor Command reference GUID of the workflow instance.
Status	A string indicating the current status of the workflow instance. The possible statuses are: • CanceledForRestart • Complete • Failed • Rejected • Running • Suspended
CurrentStepID	A string indicating the Keyfactor Command reference GUID of the workflow instance step.
StatusMessage	A string indicating the current status message for the workflow instance. Possible status messages vary and may include: • Access is denied • Awaiting *#* more approval(s) from approval roles. • Either the credentials are invalid, or the CA on [*CA hostname*] is not running • Issued • Issued. The private key was successfully retained. • Post-process Failed: *[Message indicating reason for failure generally from the CA*] • Pre-process failed: *[Message indicating details of the failure*] • Revoked • Step 'Keyfactor-Enroll' failed: *[Message indicating details of the failure*] • Step 'Keyfactor-Revoke' failed:*[Message indicating details of the failure*] • Step [*custom step name*] failed: [*Message indicating details of the failure*] • Taken Under Submission. The certificate template requires manager approval, and is marked as pending. • Workflow rejected by user with Id *#*.
Definition	An array containing the workflow definition. Workflow definition data includes: **Name** / **Description** Id — A string indicating the Keyfactor Command reference GUID of the workflow definition. DisplayName — A string indicating the display name defined for the workflow definition.

<table>

<tr><td>StartDate</td><td>A string indicating the date and time when the instance was initiated.</td></tr>
<tr><td>ReferenceId</td><td>A integer indicating the Keyfactor Command reference ID for the workflow instance.</td></tr>
</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.32.5 GET Workflow Instances AssignedToMe

The GET /Workflow/Instances/AssignedToMe method is used to retrieve the list of initiated workflows awaiting input from the user making the API request. This method returns HTTP 200 OK on a success with details about the workflow instances.

Note: If a workflow instance is initiated for a workflow definition that has more than one step requiring input (signals), a user can only provide that input (e.g. approve or deny a require approval request) at the step in the workflow instance where the workflow instance was suspended pending input. The user cannot jump ahead and provide input for future steps in the workflow that have not yet occurred.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
WorkflowInstances: *ReadAll* OR
WorkflowInstances: *ReadAssignedToMe*

Table 662: GET Workflow Instances AssignedToMe Input Parameters

Name	In	Description
queryString	Query	A string containing a query to limit the results (e.g. field1 -eq value1 AND field2 -gt value2). The default is to return all records. Fields available for querying through the API for the most part match those that appear in the Keyfactor Command Management Portal search dropdowns for the same feature. For querying guidelines, refer to the *Keyfactor Command Reference Guide*: Using the Workflow Instances Search Feature on page 282. The query fields supported for this endpoint are: • *DefinitionId* (workflow definition ID) • *Id* (workflow instance GUID) • *InitiatingUserName* (DOMAIN\\username) • *LastModified* • *ReferenceId* (workflow instance integer ID) • *StartDate* • *Status* • *Title* • *WorkflowType*
pageReturned	Query	An integer that specifies how many multiples of the returnLimit to skip and offset by before returning results, to enable paging. The default is 1.
returnLimit	Query	An integer that specifies how many results to return per page. The default is 50.
sortField	Query	A string containing the property by which the results should be sorted. Fields available for sorting through the API for the most part match those that appear as sortable columns in the Keyfactor Command Management Portal. The default sort field is *CurrentStepDisplayName*.
sortAscending	Query	An integer that sets the sort order on the returned results. A value of 0 sorts results in ascending order while a value of 1 sorts results in descending order. The default is ascending.

Table 663: GET Workflow Instances AssignedToMe Response Data

Name	Description
Id	A string indicating the Keyfactor Command reference GUID of the workflow instance.
Status	A string indicating the current status of the workflow instance. The possible statuses are: • CanceledForRestart • Complete • Failed • Rejected • Running • Suspended Only instances with a Status of *Suspended* are returned using this method.
CurrentStepID	A string indicating the Keyfactor Command reference GUID of the workflow instance step.
StatusMessage	A string indicating the current status message for the workflow instance. Possible status messages vary and may include: • Access is denied • Awaiting # more approval(s) from approval roles. • Either the credentials are invalid, or the CA on [*CA hostname*] is not running • Issued • Issued. The private key was successfully retained. • Post-process Failed: *[Message indicating reason for failure generally from the CA*] • Pre-process failed: *[Message indicating details of the failure*] • Revoked • Step 'Keyfactor-Enroll' failed: *[Message indicating details of the failure*] • Step 'Keyfactor-Revoke' failed:*[Message indicating details of the failure*] • Step [*custom step name*] failed: [*Message indicating details of the failure*] • Taken Under Submission. The certificate template requires manager approval, and is marked as pending. • Workflow rejected by user with Id *#*. Only instances with a *StatusMessage* of *Awaiting # more approval(s) from approval roles.* are returned using this method.
Definition	An array containing the workflow definition. Workflow definition data includes: **Name** / **Description** Id — A string indicating the Keyfactor Command reference GUID of the workflow definition.

<table>
<tr><th>Name</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Name</th><th>Description</th></tr>

</table>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.32.6 POST Workflow Instances Instance Id Stop

The POST /Workflow/Instances/{instanceId}/Stop method is used to stop the workflow instance with the specified GUID, preventing it from continuing. This endpoint returns 204 with no content upon success.

Note: Only workflow instances with a Status of *Suspended* can be stopped.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: WorkflowInstances: *Manage*

Table 664: POST Workflow Instances {instanceid} Stop Input Parameters

Name	In	Description
instanceId	Path	**Required**. A string indicating the Keyfactor Command reference GUID of the workflow instance to stop. Use the *GET /Workflow/Instances* method (see GET Workflow Instances on page 2092) to retrieve a list of all the workflow instances to determine the GUID.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.32.7 POST Workflow Instances Instance ID Signals

The POST /Workflow/Instances/{instanceId}/Signals method is used to input signals to the workflow instance with the specified GUID. This endpoint returns 204 with no content upon success.

Note: If a workflow instance is initiated for a workflow definition that has more than one step requiring input (signals), a user can only provide that input (e.g. approve or deny a require approval request) at the step in the workflow instance where the workflow instance was suspended pending input. The user cannot jump ahead and provide input for future steps in the workflow that have not yet occurred.

Note: A locking conflict may occur if two (or more) users attempt to provide input to a workflow instance (e.g. approve a request) at exactly the same time. If this happens, input from only one of the users will be reflected in the Management Portal, and the workflow instance will not be moved along to the next step if it should have been with input from the two users. The other input is still accepted, however, and there is a scheduled task that runs daily and attempts to continue all suspended workflows that may be eligible to continue but have not done so due to locking conflicts.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature: The user executing the request must hold at least one security role ID configured in the workflow definition step for which signal data is being input.

Table 665: POST Workflow Instances {instanceid} Signals Input Parameters

<table>
<tr><th>Name</th><th>In</th><th>Description</th></tr>
<tr><td>instanceId</td><td>Path</td><td>Required. A string indicating the Keyfactor Command reference GUID of the workflow instance to which to input a signal.
Use the GET /Workflow/Instances method (see GET Workflow Instances on page 2092) to retrieve a list of all the workflow instances to determine the GUID.</td></tr>
<tr><td>signal</td><td>Body</td><td>Required. An array containing the data used at the point in the workflow step where the workflow needs to continue based on user input. These will vary depending on the type of workflow and the type of step. RequireApproval signal values are:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>SignalKey</td><td>Required. A string indicating the key for the signal. This is made up of the unique name for the step within the definition plus the signal type, separated by a period (UniqueName.SignalType). For a Require Approval step, the key input type will be ApprovalStatus, so the full SignalKey will look something like:
<code>RequireApproval1.ApprovalStatus</code>
Use the GET /Workflow/Definitions/{definitionid} method (see GET Workflow Definitions Definition ID on page 1979) to return workflow details including the workflow steps to determine the UniqueName of the step for which you want to input a signal or one of the GET methods for workflow instances (see GET Workflow Instances on page 2092, GET Workflow Instances AssignedToMe on page 2098, or GET Workflow Instances My on page 2095) to return the CurrentStepUniqueName.</td></tr>
<tr><td>Data</td><td>Required. An array containing key/value pairs providing the input information for the signal. The key(s) will vary depending on the signal. RequireApproval signal data values are:
<table>
<tr><th>Key</th><th>Value</th></tr>
<tr><td>Approved</td><td>Required. A Boolean indicating whether the request is approved (true) or denied (false).</td></tr>
<tr><td>Comment</td><td>A string containing a comment to associate with the signal. The maximum comment length is 500 characters.</td></tr>
</table></td></tr>
</table>
For example, to approve a Require Approval step called RequireApproval1 with a comment:
<pre>{</pre></td></tr>
</table>

Name	In	Description

		<pre>"SignalKey": "RequireApproval1.ApprovalStatus",
		"Data": {
		"Approved": "True",
		"Comment": "Here is my comment."
		}
		}</pre>

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.2.32.8 POST Workflow Instances Instance Id Restart

The POST /Workflow/Instances/{instanceId}/Restart method is used to restart the workflow instance with the specified GUID. This can be used either after it has reached a failed state and the failure has been corrected (e.g. a CA was not responding when an enrollment was attempted or a PowerShell script failed to run to completion) or midstream while it's still active but in a suspended state waiting for signals to introduce a new version of the workflow definition. The workflow instance will restart from the beginning. This endpoint returns 204 with no content upon success.

Note: Only workflow instances with a Status of *Failed* or *Suspended* can be restarted.

Tip: The following permissions (see Security Overview on page 574) are required to use this feature:
WorkflowInstances: *Manage*
WorkflowDefinitions: *Read*

Table 666: POST Workflow Instances {instanceid} Restart Input Parameters

Name	In	Description
instanceId	Path	**Required**. A string indicating the Keyfactor Command reference GUID of the workflow instance to restart. Use the *GET /Workflow/Instances* method (see GET Workflow Instances on page 2092) to retrieve a list of all the workflow instances to determine the GUID. **Note:** When you restart an instance, it will be issued a new instance ID.
version	Body	An integer indicating the version number of the workflow definition. If no version is specified, the workflow will be restarted using the most recently published version.

Tip: For code examples, see the *Keyfactor API Endpoint Utility*. To find the embedded web copy of this utility, click the help icon (?) at the top of the Keyfactor Command Management Portal page next to the **Log Out** button.

3.3 Classic API

The Keyfactor Classic API, also known as the CMS API, is the Web API that has been provided with Keyfactor Command for several product generations. The Classic API may be needed in your environment if you're upgrading and have written API applications using the Classic API. If you're new to building an API application to work with Keyfactor Command, Keyfactor strongly recommends that you use the newer Keyfactor API (see Keyfactor API on page 722).

3.3.1 Security Role Overview

In order to use the Classic API, certain security role permissions must be granted to the identity used by the client to authenticate to the API. Specifically, the user must have the *API Read* permission to make any requests. Beyond this, different API endpoints have different requirements (see Classic API Security Role Requirements below).

Where the table indicates that *Certificate Store Management* permissions are required, this can either be global permissions to all certificate stores or permissions granted to the specific certificate store using certificate store container security. Likewise, where *Certificates* permissions are required, this can either be global certificate permissions on all certificates or permissions granted to a specific certificate or set of certificates using certificate collection security. See the *Keyfactor Command Reference Guide* for more information about container and collection security.

Table 667: Classic API Security Role Requirements

Endpoint	Security Role Permissions
ApiApp/1/GetApiApps	System Settings: Read
ApiApp/1/AddApiApp	System Settings: Modify
ApiApp/1/EditApiApp	System Settings: Modify
ApiApp/1/DeleteApiApp	System Settings: Modify
CertEnroll/1/Pkcs10	None
CertEnroll/1/Pkcs12	None
CertEnroll/1/Templates	None
CertEnroll/1/Token	None
CertEnroll/2/Pkcs10	None

Endpoint	Security Role Permissions
CertEnroll/2/Pkcs12	None
CertEnroll/2/Templates	None
CertEnroll/2/Token	None
CertEnroll/3/Pkcs10	None
CertEnroll/3/Pkcs12	None
CertEnroll/3/Renew	Certificate Store Management: Read and Schedule
CertEnroll/3/Templates	None
Certificates/1/Metafield	Certificates: Modify and Certificate Metadata Types: Read
Certificates/2/Import	Certificates: Import
Certificates/3/Contents	Certificates: Read
Certificates/3/Count	Certificates: Read
Certificates/3/PublishCRL	PKI Management: Modify
Certificates/3/Recover	Certificates: Recover
Certificates/3/Revoke	Certificates: Revoke
Certificates/3/Search	Certificates: Read
Certstore/1/AddCert	Certificate Store Management: Read and Schedule, and Certificates: Read
Certstore/1/AddCertStore	Certificate Store Management: Modify
Certstore/1/AddCertStoreServer	Certificate Store Management: Modify
Certstore/1/AddPFX	Certificate Store Management: Read and Schedule
Certstore/1/CreateJKS	Certificate Store Management: Modify
Certstore/1/EditCertStore	Certificate Store Management: Modify
Certstore/1/EditCertStoreServer	Certificate Store Management: Modify
Certstore/1/Inventory	Certificate Store Management: Read
Certstore/1/Keystores	Certificate Store Management: Read

Endpoint	Security Role Permissions
Certstore/1/Remove	Certificate Store Management: Schedule and Certificates: Read
Certstore/1/ScheduleInventory	Certificate Store Management: Modify
Metadata/2/Compare	Certificates: Read and Certificate Metadata Types: Read
Metadata/2/Get	Certificates: Read and Certificate Metadata Types: Read
Metadata/2/Set	Certificates: Modify and Certificate Metadata Types: Read
Metadata/3/Get	Certificates: Read and Certificate Metadata Types: Read
Metadata/3/GetDefinition	Certificate Metadata Types: Read
Metadata/3/Set	Certificates: Modify and Certificate Metadata Types: Read
Security/1/GetIdentities	Security Settings: Read
Security/1/AddIdentity	Security Settings: Modify
Security/1/DeleteIdentity	Security Settings: Modify
Security/1/GetRoles	Security Settings: Read
Security/1/AddRole	Security Settings: Modify
Security/1/EditRole	Security Settings: Modify
Security/1/DeleteRole	Security Settings: Modify
SSL/1/AddEndpoint	SSL Management: Modify
SSL/1/AddEndpointGroup	SSL Management: Modify
SSL/1/Agents	SSL Management: Read
SSL/1/EndpointGroups	SSL Management: Read
Workflow/1/ApproveRequest	Workflow: Read and Participate
Workflow/1/DenyRequest	Workflow: Read and Participate

Endpoint	Security Role Permissions
Workflow/1/PendingList	Workflow: Read and Participate
Status	None
vSCEP	Configured through the Keyfactor Command Configuration Wizard or through the Application Settings page in the Keyfactor Command Management Portal.

3.3.2 ApiApp

The ApiApp component of the Keyfactor Web APIs includes all methods necessary to programmatically add, edit, get and delete API Applications. The complete set of endpoints is shown in3.3.2 ApiApp.

Table 668: ApiApp Endpoints

Endpoint	Method	Description
/1/GetApiApps	GET	Returns a list of the API applications
/1/AddApiApp	POST	Add an API application to Keyfactor Command
/1/EditApiApp	POST	Edit an API application in Keyfactor Command
/1/DeleteApiApp	POST	Deletes and API application from Keyfactor Command

3.3.2.1 ApiAPP GetApiApps

The GET GetApiApps endpoint returns a list of all API Applications defined in Keyfactor Command with the Id, Name, Key, Secret, CAId, CAConfiguration, TemplateId, TemplateName, TemplateForest and whether the Application is Enabled or not. No parameters or extra headers are required for this method.

Example Request

GET http://<host>/CMSApi/ApiApp/1/GetApiApps

Example Response

Status Code: 200

```
[
	{
		"Id": "<Id>",
		"Name": "<name>",
		"Key": "<hexadecimal key>",
```

```
            "Secret": "<hexadecimal secret>",
            “Enabled”: “True”,
            "CAId": "<CA Id>",
            "CAConfiguration": "<CA Host Name>\\<CA Logical Name>",
            "TemplateId": "<Template Id>",
            "TemplateName": "<Template Common Name>",
            "TemplateForest": "<Template Forest>"
      }
]
```

3.3.2.2 ApiApp AddApiApp

The POST AddApiApp endpoint adds an API Application to Keyfactor Command. It returns the Id of the newly added Application. Table 8 - AddApiApp Parameters shows the parameters that are used for the creation of API Applications through the Keyfactor Web APIs.

Table 669: AddApiApp Parameters

Parameter Name	Parameter Description
Name	The name of the API Application. This parameter is required.
Key	The Key used for the API Application. This parameter is required.
Secret	The Secret used for the API Application. This parameter is required.
Enabled	The Enabled parameter tells whether the API Application is enabled or not. This parameter is optional.
CA	The CA parameter sets the CA for the API Application. The format used for this parameter is HostName\\LogicalName. This parameter is optional.
Template	The Template parameter sets the template that is used with the API Application. This should be the template short name. This parameter is optional.

Example Request

POST http://<host>/CMSApi/ApiApp/1/AddApiApp HTTP/1.1

```
{
      "Name": "<Name>",
      "Key": "<hexadecimal key>",
      "Secret": "<hexadecimal secret>",
      "Enabled": true,
      "CA": "<CA Host Name>\\<CA Logical Name>",
```

```
        "Template": "<Template Common Name>"
}
```

Example Response

Status Code: 200

```
{
        "Id": <Id>
}
```

3.3.2.3 ApiApp EditApiApp

The POST EditApiApp endpoint allows certain aspects of an API Application definition to be updated. The only aspect of the API Application that cannot be updated is the Id. The response has the same elements as the GetApiApps call except for a single Api Application. Table 9 – EditApiApp Request Parameters holds the Parameters for the request.

Table 670: AddApiApp Parameters

Parameter Name	Parameter Description
Id	The Id of the API Application that is to be updated. This parameter is required.
Name	The name that the API Application will be updated to. This parameter is optional.
Key	The Key that the API Application will be updated to. This parameter is optional.
Secret	The Secret that the API Application will be updated to. This parameter is optional.
Enabled	The Enabled state the API Application will be updated to. This parameter is optional.
CAId	The Id of the Certification Authority the API Application will be updated to. This is an alternative to CaConfiguration. This parameter is optional.
CaConfiguration	The CA Configuration the API Application will be updated to. The format for the Configuration is Host.Name\\Logical-Name. This is an alternative to CAId. This parameter is optional.
TemplateId	The Id of the Template that the API Application will be updated to. This is an alternative to TemplateName. This parameter is optional.
TemplateName	The Name of the Template the API Application will be updated to. The name of the template should be the short name. This is an alternative to Template Id. This parameter is optional.

Example Request

POST http://<host>/CMSApi/ApiApp/1/EditApiApp

```
{
       "Id": <Id>,
       "Name": "<Name>",
       "Key": "<hexadecimal key>",
       "Secret": "<hexadecimal secret>",
       "Enabled": true,
       "CAId": <CA Id>,
       "TemplateName": "<Template Common Name>"
}
```

Example Response

Status Code: 200

```
{
       "Id": "<Id>",
       "Name": "<Name>",
       "Key": "<hexadecimal key>",
       "Secret": “<hexadecimal secret>”,
       "Enabled": "True",
       "CAId": "<CA Id>",
       "CAConfiguration": "<CA Host Name>\\<CA Logical Name",
       "TemplateId": "<Template Id>",
       "TemplateName": "<Template Common Name>",
       "TemplateForest": " <Template Forest>"
}
```

3.3.2.4 ApiApp DeleteApiApp

The POST DeleteApiApp endpoint removes an API Application from Keyfactor Command. The POST request must contain a JSON string containing the Identity Id. This method returns a 200 a message stating the API App was deleted successfully.

Example Request

POST http://<host>/CMSApi/ApiApp/1/DeleteApiApp HTTP/1.1

```
{
       "Id": <Id>
}
```

Example Response

Status Code: 200

```
{
       "Message": "The Api Application was deleted"
}
```

3.3.3 CertEnroll

The CertEnroll component of the Keyfactor Web APIs includes all methods necessary to programmatically request and obtain a certificate. Keyfactor Command supports enrollment through Microsoft Active Directory Certificate Services Certificate Authorities, both in the local Active Directory forest and, by using Keyfactor Gateways, in remote domains and a variety of public CA vendors. Contact your Keyfactor representative for more information about Keyfactor Gateways, including the most recent list of supported Certificate Authorities.) The CertEnroll component allows enrollment through all CAs configured in your Keyfactor Command environment. The API supports two variations of enrollment. The more secure variant allows the client application to generate the certificate's public/private keypair on the device issuing the request, so that the private key is never transmitted or stored anywhere else. This model is useful in scenarios where the key doesn't need to be archived or exported. The second model lets the server generate the keys, returning the resulting cert and keypair as a PFX/PKCS12 blob. This method is suitable when the key does need to be exported or archived, or when the client is not capable of generating a keypair itself.

There are three versions of the CertEnroll API, each with separate methods for the two enrollment variations, and up to three auxiliary methods to help formulate a successful enrollment request or perform related operations. The complete set of endpoints is given here in Table 671: CertEnroll Endpoints.

Table 671: CertEnroll Endpoints

Endpoint	Method	Description
/1/Status	GET	A synonym for GET /Status, included on this path for backwards-compatibility
/1/Templates	GET	Return a list of certificate templates available to this API application
/1/Token	GET	Retrieve a temporary authentication token to be used with an enrollment request
/1/Pkcs10	POST	Obtain a certificate by providing a CSR, using a key generated by the client
/1/Pkcs12	POST	Obtain a certificate and private key from Keyfactor Command by providing certain certificate attributes
/2/Status	GET	A synonym for GET /Status, included on this path for backwards-compatibility
/2/Templates	GET	Return a list of certificate templates available to this API application

Endpoint	Method	Description
/2/Token	GET	Retrieve a temporary authentication token to be used with an enrollment request
/2/Pkcs10	POST	Obtain a certificate by providing a CSR, using a key generated by the client
/2/Pkcs12	POST	Obtain a certificate and private key from Keyfactor Command by providing certain certificate attributes
/3/Templates	GET	Return a list of certificate templates available to this API application
/3/Renew	POST	Obtain a new certificate based on content from an existing certificate in Keyfactor Command
/3/Pkcs10	POST	Obtain a certificate by providing a CSR, using a key generated by the client
/3/Pkcs12	POST	Obtain a certificate and private key from Keyfactor Command by providing certain certificate attributes

For historic reasons, slight differences in the template format necessitated differentiating the methods into a "version 1" and "version 2", with the same set of methods. Then, to allow simplification of the built-in security mechanisms, version 3 of these methods was introduced. In most cases, applications should use the CertEnrollv3 methods if taking advantage of this security mechanism (as described below) and CertEnrollv2 if not.

This Keyfactor Command API component supports an optional application authentication feature to restrict the API to selected third-party software clients. It uses a public application key and a private application secret. The application key identifies the API client application to the server and is sent as part of the HTTP headers for all enrollment endpoints. The application secret is used to compute an HMAC-SHA1 signature that is sent in an HTTP header for certain endpoints. The combination of the application key and the computed signature allows Keyfactor Command to verify the origin and the authenticity of the enrollment request. Although Basic authentication credentials are required in order to connect to the API, this allows a single user to configure different applications for different templates and have the restrictions enforced. The secret allows secure authentication and prevents attackers from attempting to replay successful enrollment requests. The calculation of this HMAC signature differs between v2 and v3 of the API. The different computations are covered in Table 672: CertEnroll Security Headers.

Another difference between v1, v2 and v3 is that v3 will import the certificate immediately and sync the row from the CA database after the certificate has been issued, whereas v1 and v2 require a manual import of the certificate after it has been issued.

Each application should have its own unique application key and secret pair embedded in the application, as well as in secure storage on the server. These keys can be registered in the API Applications section of the System Settings menu on the Keyfactor Command Management Portal. Giving each application its own key and secret pair provides these advantages:

- An application can be restricted to request specific certificate templates and from specific CAs.
- One application key can be disabled while leaving other application keys enabled. This allows insecure or compromised versions of an application to be disabled without affecting up-to-date users.

Table 672: CertEnroll Security Headers

Header Name	Header Value
X-CSS-CMS-AppKey	This header contains the application key assigned to this particular application. This header is a base-64-encoded string created from the key's byte sequence, and not the ASCII/UTF-8 hexadecimal representation of that byte sequence. For example, if the key is entered in the API Applications section as "030303030303030303FF", this represents the bit pattern "00000011000000110000001100000011000000110000001100000011000000111111111", with base-64 encoding "AwMDAwMDAwMD/w==". In Python, this conversion can be accomplished with the following code: import base64 hexKey = "030303030303030303FF" binKey = hexKey.decode("hex")) b64Key = base64.b64encode(binKey)
X-CSS-CMS-Token	This header field contains the temporary token that was previously obtained from the GET Token method. Like the application key, this header is a base-64-encoded string created from the binary form of the token, and not the ASCII/UTF-8 hexadecimal representation actually returned by the response to the GET Token. This is required for the v1 and v2 endpoints only.
X-CSS-CMS-Signature	This header field contains an HMAC-SHA-1 message signature computed from the request. Producing this signature proves that the client has access to the application secret value that is also present in the server's configuration, that the message has been transmitted without modification, and that transmission is recent. This is required for all enrollment endpoints, although this requirement can be disabled through the application settings in the management console. The computation of this signature differs between versions; all versions are a base-64 encoding of a SHA-1 hash, but the content to be hashed varies. In general, v1 and v2 GET methods hash the URL and Token; v1 and v2 POST methods hash the URL, Token, and request body; v3 GET methods do not require a signature; and v3 POST methods hash the request body only. The computation of HMAC signatures is significantly easier for v3 methods. Sample Python code is included in Table 673: CertEnroll HMAC computations in Python for each computation type.

Table 673: CertEnroll HMAC computations in Python

Endpoints	Signature

GET Templates (v1 and v2)	token = json.loads(GET_Token_ResponseBody)["SessionTokenValue"]
	URLPath = "/CMSApi/CertEnroll/2/Templates"
	requestDataString = URLPath + token;
	appSecretBytes = appSecretString.decode("hex")
	signature = hmac.new(appSecretBytes, requestDataString, hashlib.sha1).hexdigest();
	headers["X-CSS-CMS-Signature"] = base64.b64encode(signature.decode("hex"));

POST	token = json.loads(GET_Token_ResponseBody)["SessionTokenValue"]

Endpoints	Signature

/1/Pkcs10,
/1/Pkcs12,
/2/Pkcs10,
/2/Pkcs12
	URLPath = "/CMSApi/CertEnroll/2/Pkcs12"
	body='{"Flags":0,"TemplateName":"User","Pkcs12Password":"lily1234","SubjectNameAttributes":null}'
	Note: For these methods, the body must be formatted exactly as above, as far as parameter order, capitalization, and whitespace. This is one reason v3 signatures are easier to use.
	requestDataString = URLPath + token + body
	appSecretBytes = appSecretString.decode("hex")
	signature = hmac.new(appSecretBytes, requestDataString, hashlib.sha1).hexdigest();
	headers["X-CSS-CMS-Signature"] = base64.b64encode(signature.decode("hex"));

POST
/3/Pkcs10 and
/3/Pkcs12
	data='{"Flags":0,"TemplateName":"User","Pkcs12Password":"lily1234","SubjectNameAttributes":null}'
	body = '{"Timestamp" : '" + datetime.datetime.utcnow().isoformat()+ '", "Request" : ' + data + '}'
	Note: For these methods, the request can be formatted in any equivalent json format without regard to capitalization, whitespace, or order of elements. This is one reason v3 signatures are easier to use.
	appSecretBytes = appSecretString.decode("hex")
	signature = hmac.new(appSecretBytes, body, hashlib.sha1).hexdigest();
	headers["X-CSS-CMS-Signature"] = base64.b64encode(signature.decode("hex"));

3.3.3.1 CertEnroll Token

The GET Token request returns a session token that is used in subsequent calls to v1 or v2 enrollment endpoints to authenticate the software client to the server. By default, the token has an expiration time of 10 minutes (configurable in the Keyfactor Command Management Portal Application Settings). Using a token after it is expired will result in an error.

Example Request

GET http://<host>/CMSApi/CertEnroll/1/Token HTTP/1.1

Example Response

```
{
	"SessionTokenValue":"F715F307DBE0DD5A9894260DBF0643C042173698"
}
```

3.3.3.2 CertEnroll Templates

The Templates methods return the list of templates configured and enabled for use by the application (identified by the X-CSS-CMS-AppKey HTTP header). The set of fields returned for a template differs from version 1 to version 2, but versions 2 and 3 return the same content. No parameters are required for these requests—only the app key in the header, formatted as described in Table 672: CertEnroll Security Headers—but the response formats are given in Table 674: GET /2/Templates and /3/Templates Response Body.

Important: As of release 9.0 of the Classic API, version 1 of CertEnroll/1/Templates has been removed from the product and is no longer supported.

Table 674: GET /2/Templates and /3/Templates Response Body

Parameter Name	Parameter Value
DisplayName	Long/Friendly name of the template.
CommonName	Short name of the template.
Oid	Object Identifier for this template.
KeySize	String representation of Key Size in bits, or Unknown.

Example Request

GET http://<host>/CMSApi/CertEnroll/3/Templates HTTP/1.1

X-CSS-CMS-AppKey: AAAAAAAAAAAAAA==

X-CSS-CMS-Token: A0sTeMd9PT6XPw2BdqWb9PkErQk= [Version 2 only]

Example Response

Version 2 and 3

```
[
	{
		"DisplayName":"UserServer",
		"CommonName":"UserServer",
		"Oid":"1.3.6.1.4.1.311.21.8.2290866.14924250.4277929.6978074.6651290.247.14988018.16169587",
		"KeySize":"2048"
	}
]
```

3.3.3.3 CertEnroll Pkcs10

The PKCS10 method provides enrollment with on-device key generation. The basic workflow with on-device key generation is:

1. Client application retrieves list of available certificate templates using the Keyfactor Command API.
2. Client generates a public/private key pair based on the key size requirements from the selected template.
3. Client creates a PKCS10 Certificate Signing Request (CSR) using the keypair and template attributes.
4. Client sends the PKCS10 request and selected template name to the API which submits the request to the enterprise CA and returns the certificates received from the CA to the software client.

If successful, the response from the CA will be a PKCS#7 message containing the issued certificate and (optionally) the certificate chain. Once the response is received, a software client can construct a PKCS12 package with the previously generated key pair and the issued certificates, import the keys and certificates into an application-specific store, such as Apple's KeyChain Services or a Java Keystore, or perform any other processing required. The flow (for versions 1 and 2) is shown in Figure 430: Pkcs#10-Based Enrollment Request. The version 3 flow is identical except that a token is not required for enrollment, so the initial exchange with the *token* endpoint is not needed. The difference in version 3 is explained in Table 672: CertEnroll Security Headers.

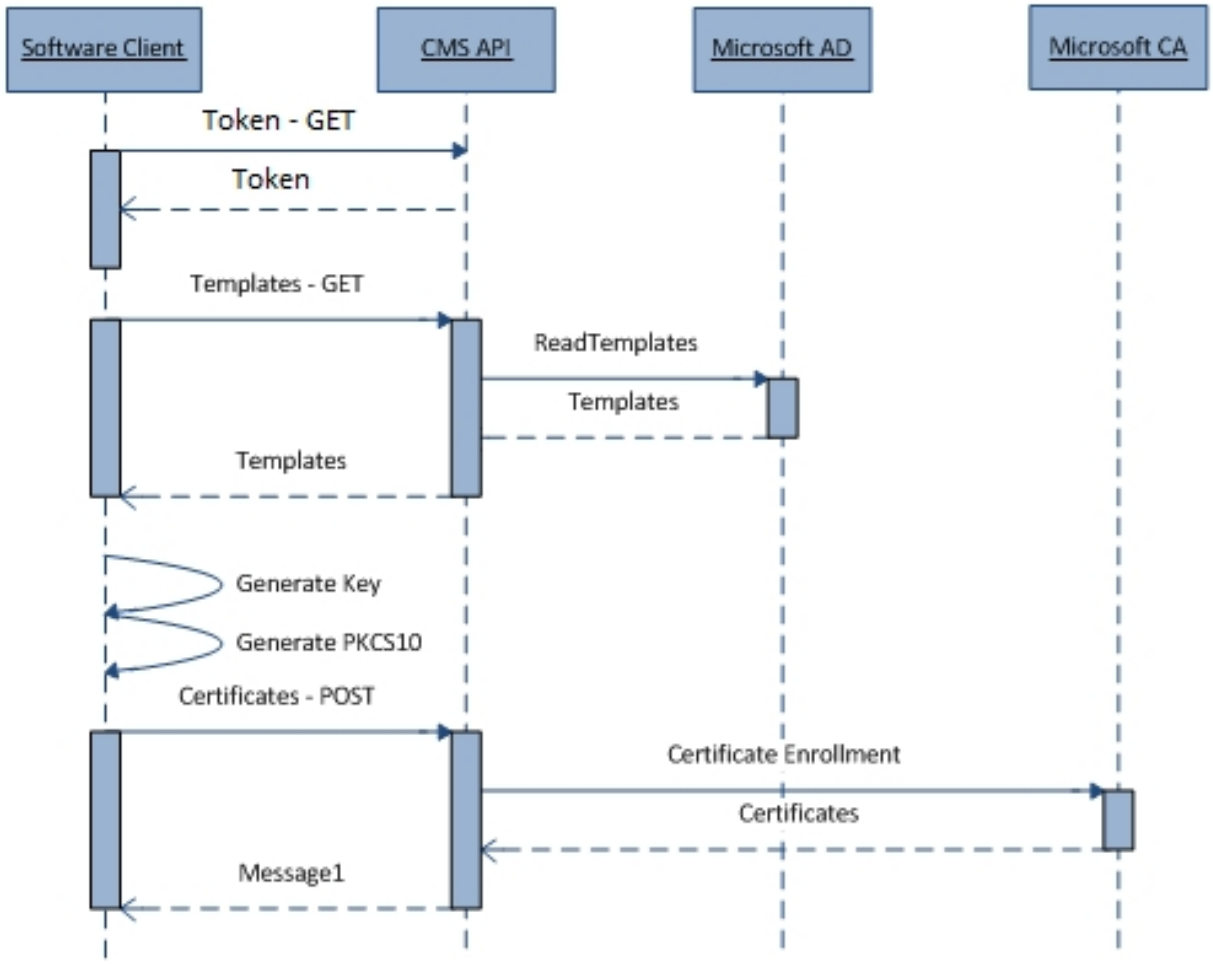

Figure 430: Pkcs#10-Based Enrollment Request

The PKCS10-based method is the most secure way to enroll for certificates with Keyfactor Command. The PKCS10 method utilizes on-device key generation instead of the server-based key generation used for the PKCS12 method. The PKCS10 method also requires the use of a certificate template that populates the subject and/or subject alternate name from Active Directory. This reliance on certificate templates allows Keyfactor Command to utilize the security mechanisms built into the Microsoft CA Services.

To use this method, the following configuration should be present on the Keyfactor Command server and in its domain:

- IIS application pool configured with a non-administrator domain member account
- API Application with valid key, secret, template, and CA
- Certificate template configured to:
    - Populate subject and/or subject alternate name (SAN) fields from AD as needed. While the PKCS#10 request may contain data for these fields, the selected certificate template may replace those values with information from Active Directory.

- Not allow private key exportation
- Grant enroll permission to all users who may enroll for a certificate

The request parameters that should be sent for version 1 and 2 of the enrollment are listed in Table 675: POST /1/Pkcs10 and /2/Pkcs10 Request Body and for version 3 in Table 676: POST /3/Pkcs10 Request Body, while the response format (for all versions) is given in Table 677: POST /*/Pkcs10 Response Body:

Table 675: POST /1/Pkcs10 and /2/Pkcs10 Request Body

Parameter Name	Parameter Value
Flags	Bit flags that determine the enrollment behavior. At this time, the only available bit flag is: • 0x01 = Include certificate only (default is to return certificate + trust chain)
TemplateName	Name of the certificate template to use for enrollment. This name must match one of the template names configured for this application key in the API Applications page.
Pkcs10Request	Contains a base-64-encoded PKCS#10 request generated on the device. The key sizes used to generate the PKCS#10 request must match the key size specified in the certificate template.
MetadataList	A list of key value pairs for each metadata item that is to be set on the issued certificate in Keyfactor Command. This parameter is optional.

In version 3 of the API, the fields used by versions 1 and 2 are wrapped in an outer envelope and sent along with a timestamp. By including this timestamp in the request body and using this as part of the HMAC signature computation, the need for a current API access token is eliminated without reducing security. The request structure for version 3 of this endpoint is shown in Table 676: POST /3/Pkcs10 Request Body:

Table 676: POST /3/Pkcs10 Request Body

Parameter Name	Parameter Value
Timestamp	ISO 8601 Timestamp in UTC timezone, e.g. "2018-11-22T20:41:08.440Z"
Request	JSON object in the same format as a version 1/2 Pkcs10 enrollment request (see Table 675: POST /1/Pkcs10 and /2/Pkcs10 Request Body).

Table 677: POST //Pkcs10 Response Body*

Parameter Name	Parameter Value
SerialNumber	String containing the hexadecimal serial number of the issued certificate.
IssuerDN	Distinguished Name of the certificate's issuer.

Parameter Name	Parameter Value
Thumbprint	Thumbprint of the issued certificate.
CMSID	Identifier for this certificate in Keyfactor Command. Can be used to identify the cert in future API requests.
CMSRequestId	Identifier for the certificate request in Keyfactor Command. Can be used if certificate is pending issuance.
Certificates	If the CERT_ONLY flag (0x01) is set in the request, then the response is a base-64 encoding of the DER-encoded cert. If the CERT_ONLY flag is not set, the response is a base-64 encoding of a PKCS7 containing the cert and its chain.
RequestDisposition	Value returned by the CA in response to this certificate request
DispositionMessage	Message accompanying the disposition value returned by the CA

Example Request

Versions 1 and 2

POST http://<host>/CMSApi/CertEnroll/1/Pkcs10 HTTP/1.1

```
{
	"Flags":0,
	"TemplateName": "User",
	"Pkcs10Request":"-----BEGIN CERTIFICATE REQUEST-----
		<base64-encoded-certificate-request>
		-----END CERTIFICATE REQUEST-----\n"
}
```

Example Request

Version 3

```
{
	"Timestamp" : "2017-12-18T19:56:12.365Z",
	"Request": {
		"Flags":0,
		"TemplateName": "User",
		"Pkcs10Request":"-----BEGIN CERTIFICATE REQUEST-----
		<base64-encoded-certificate-request>
		-----END CERTIFICATE REQUEST-----",
```

```
               "MetadataList":{"<metadata type name>":"<metadata value>","<metadata type name>":"<metadata
value">}
       }
}
```

Example Response

```
{
       "SerialNumber": "2684C97728678A944A67C03E7192785B",
       "IssuerDN": "CN=CorpCA1, DC=keyexample, DC=com",
       "Thumbprint": "FDB3A0F4ADCF9C39A2BB639898EE1670DFDBF5BB",
       "CMSID": 5,
       "CMSRequestId": 3,
       "Certificates": <PEM-encoded certificates>
       "RequestDisposition": "Issued",
       "DispositionMessage": ""
}
```

3.3.3.4 CertEnroll Pkcs12

The PCKS12-based POST enrolls for a certificate with a server-generated private key. It generates a PKCS#12 file that is protected by the password specified in the request and returns a base-64-encoded PKCS#12 response if successful.

The basic workflow with server-based key generation is:

1. Third-party software client retrieves a list of available certificate templates using the Keyfactor Command API.
2. Third-party software client sends the selected template name and a password to the API. The Keyfactor Command component will:
    a. Generate the RSA key pair.
    b. Submit the request to the CA configured for the API application and retrieve the issued certificate.
    c. Create a PKCS12 blob with the private key, the issued certificate, and the certificate trust chain using the supplied password.
    d. Return the PKCS12 blob to the API client.

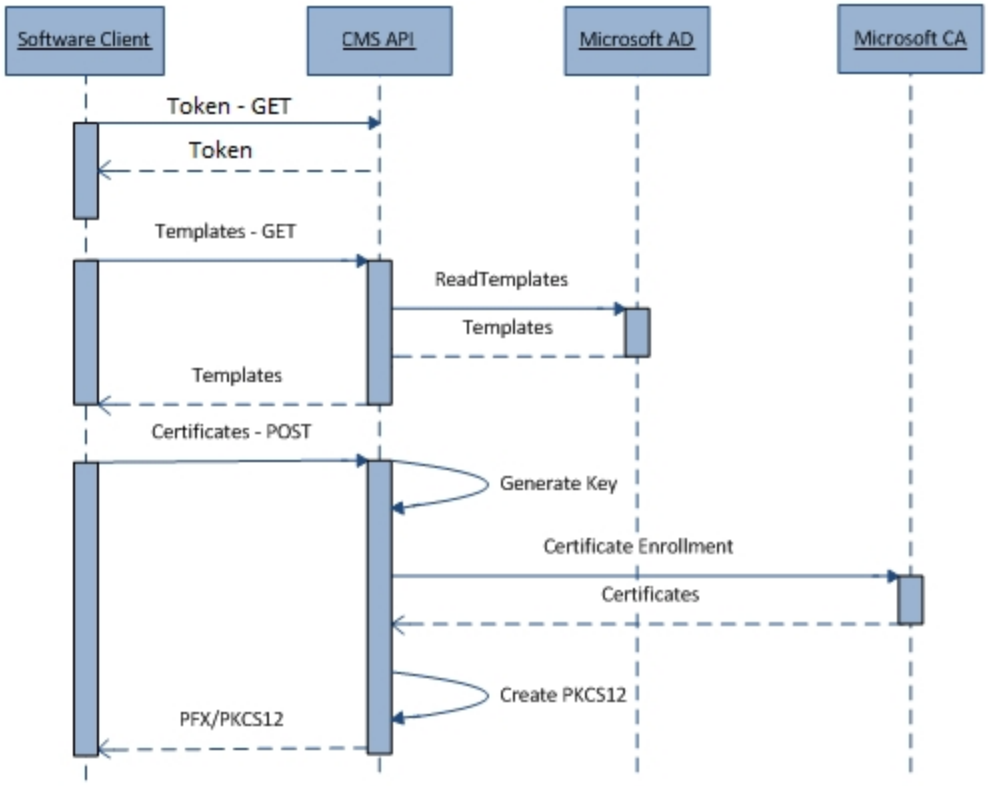

Figure 431: Pkcs#12-Based Enrollment Request

As with the Pkcs10 methods, versions 1 and 2 use the flow shown in Figure 431: Pkcs#12-Based Enrollment Request, while version 3 does not require a token and uses a timestamp instead. For these methods, keys are generated on the server and returned to the client in the form of a P12 (PFX) file. This requires that the certificate's private key is transmitted over the network and temporarily stored on the server, which can present a security risk. For this reason, Keyfactor recommends that clients which are capable of generating their own keypair and submitting a CSR use the Pkcs10 enrollment. When clients do not have the capability or the processing power to do this, the Pkcs12 offers an alternate method. Certificate templates are used on the Microsoft CA; however, the private key must be marked as exportable in the template.

To use this method, the following configuration needs to be present on the Keyfactor Command server:

- Certificate template configured to:
  - Allow the requestor (Keyfactor Command) to supply the subject and subject alternate name details
  - Allow the private key to be exported
  - Grant enroll permission to the Keyfactor Command application pool user—no other user needs enroll permissions for this template and for best security, none should be granted to other users
- IIS application pool user configured to be a non-administrative domain member account
- The *Load User Profile* option configured to **true** under the advanced settings for the application pool

The format of a Pkcs12 request is given in Table 678: POST /1/Pkcs12 and /2/Pkcs12 Request Body and Table 679: POST /3/Pkcs12 Request Body, while the response format is given in Table 680: POST /*/Pkcs12 Response Body.

Table 678: POST /1/Pkcs12 and /2/Pkcs12 Request Body

<table>
<tr><th>Parameter Name</th><th>Parameter Value</th></tr>
<tr><td>Flags</td><td>Bit flags that determine the enrollment behavior. At this time, there are no available bit flags so this value should be set to "0" (zero).</td></tr>
<tr><td>TemplateName</td><td>Name of the certificate template used for enrollment. This name must match- one of the allowed template names.</td></tr>
<tr><td>Pkcs12Password</td><td>PKCS12 password. Must be 8 or more characters.</td></tr>
<tr><td>SubjectNameAttributes</td><td>Token values that are substituted into the API subject format string. When needed values are not provided, Keyfactor Command will attempt to use the corresponding field from the requester’s AD account. If no attributes are needed in the request, you must still include this attribute and set the value to null. Also, note that, although the terms are similar, SubjectNameAttributes are NOT the same as Subject Alternative Names, which are supplied separately in the SubjectAltNameElements field.
Values can be supplied either as an array of key/value pairs or as a dictionary in the form {"Field1" : "Value1", "Field2" : "Value2"}.</td></tr>
<tr><td>SubjectAltNameElements</td><td>Contains an array of key/value pairs that represent the elements for Keyfactor Command to use when generating the certificate’s subject alternative name. This parameter is optional. The key will be the numeric subject alternative name flag (in string form), associated with the value. The valid subject alternative name flags are as follows:
<table>
<tr><th>Value</th><th>Definition</th></tr>
<tr><td>0</td><td>None</td></tr>
<tr><td>1</td><td>UPN</td></tr>
<tr><td>2</td><td>RFC822</td></tr>
<tr><td>3</td><td>DNS</td></tr>
<tr><td>4</td><td>IP Address</td></tr>
<tr><td>5</td><td>URI</td></tr>
<tr><td>6</td><td>Email</td></tr>
<tr><td>7</td><td>GUID</td></tr>
<tr><td>8</td><td>Registered Id</td></tr>
<tr><td>9</td><td>Directory name</td></tr>
</table></td></tr>
<tr><td>MetadataList</td><td>A list of key value pairs for each metadata item that is to be set on the issued certificate in Keyfactor Command. This parameter is optional.</td></tr>
</table>

Table 679: POST /3/Pkcs12 Request Body

Parameter Name	Parameter Value
Timestamp	ISO 8601 Timestamp, e.g. "2018-11-22T20:41:08.440000"
Request	JSON object in the same format as a version 1/2 Pkcs10 enrollment request (see Table 678: POST /1/Pkcs12 and /2/Pkcs12 Request Body).

Table 680: POST //Pkcs12 Response Body*

Parameter Name	Parameter Value
SerialNumber	String containing the hexadecimal serial number of the issued certificate.
IssuerDN	Distinguished Name of the certificate's issuer.
Thumbprint	Thumbprint of the issued certificate.
CMSID	Identifier for this certificate in Keyfactor Command. Can be used to identify the cert in future API requests.
CMSRequestId	Identifier for the certificate request in Keyfactor Command. Can be used if certificate is pending issuance.
Pkcs12Blob	Base-64-encoded representation of the Pkcs#12 certificate that was issued, if any.
RequestDisposition	Value returned by the CA in response to this certificate request.
DispositionMessage	Message accompanying the disposition value returned by the CA.

This method allows additional attributes to be included in the certificate's subject name. A common use for this is the inclusion of a device class identifier, such as "iPhone 4S". On the Keyfactor Command server there is a configuration property to define the format of the subject name. An example is:

```
"CN={cn},OU=Device Model {deviceType}"
```

For each of the tokens given in {brackets}, Keyfactor Command will replace the value with the corresponding value in the SubjectNameAttributes field of the request, if present. If no value is provided, it will attempt to look up the value in the requester's AD account. In this example, Keyfactor Command might replace the string "{deviceType}" with attribute value "deviceType" supplied in the SubjectNameAttributes key-value-pair structure inside of the JSON request from the API client, and (if "cn" is not specified in the request) the "{cn}" string would be replaced with the value of the "cn" property from the user's Active Directory properties. If a matching token cannot be found either in the request or in AD, no value is substituted.

Example Request

Versions 1 and 2

POST http://<host>/CMSApi/CertEnroll/2/Pkcs12 HTTP/1.1

```
{
       "Flags":0,
       "Pkcs12Password": "12341234",
       "TemplateName": "User",
       "SubjectNameAttributes": {"deviceid":"iPad"}]
}
```

Example Request

Version 3

POST http://<host>/CMSApi/CertEnroll/3/Pkcs12 HTTP/1.1

```
{
       "Timestamp" : "2017-12-18T19:56:12.365Z",
       "Request": {
              "Flags":0,
              "Pkcs12Password": "12341234",
              "TemplateName": "User",
              "SubjectNameAttributes": [{"key":"deviceid","value":"iPad"}],
              "MetadataList":{"<metadata type name>":"<value>","<metadata type name>":<value>"}
       }
}
```

Example Response

Status Code: 200

```
{
       "SerialNumber": "690003CC096AC71023934747AA00000003CC09",
       "IssuerDN": "CN=jdk-CA1, DC=jdk, DC=com",
       "Thumbprint": "04259811B3BC522093532FBA5F4C1FA3C0969A87",
       "CMSID": 8,
       "CMSRequestId": 6,
       "Pkcs12Blob": <base64-encoded PKCS#12>,
       "RequestDisposition": "Issued",
```

```
      "DispositionMessage": ""
}
```

3.3.3.5 CertEnroll Renew

Certificate renewal in Keyfactor Command allows a certificate to be issued based on data from an existing certificate. Some configurations, such as the issuing CA and template, can be made to differ between the original certificate and the renewed one. At renewal time, the new certificate can also be automatically delivered to different certificate stores managed by Keyfactor Command Agents, replacing the old certificates. This provides an easy mechanism to quickly replace expiring or compromised certificates, migrate deployed certificates from one PKI to another, or replace certificates with similar certificates using more secure cryptographic algorithms. The Renew Web API method, along with the web console and expiration alert handlers, allows access to this renewal functionality. The structure of a renew request is given Table 681: POST /3/Renew Request Body, and the response in Table 682: POST /3/Renew Response Body.

Table 681: POST /3/Renew Request Body

Parameter Name	Parameter Value
Lookup	Description of the certificate to be renewed. See Table 66: Classic API Certificate Lookup Structure.
CertStores	Array of GUIDs listing the certificate stores where the new certificate should be delivered. This must be a subset of the CertStores containing the original certificate.
Template	Certificate template to be used for the new certificate request.
CAConfiguration	Certificate authority for the new certificate, in the form "hostname\\logical name" (double-backslash required for JSON formatting).
Metadata	Optional dictionary of metadata fields and values to be associated with the newly issued certificate.
CustomPassword	Password to protect the private key of the new certificate. This field is optional and Keyfactor Command will use a randomly assigned password if this is not set.

Table 682: POST /3/Renew Response Body

Parameter Name	Parameter Value
Thumbprint	Thumbprint of the issued certificate.
CMSRequestId	Identifier for the certificate request in Keyfactor Command, if certificate is pending issuance.

Parameter Name	Parameter Value
RequestDisposition	Value returned by the CA in response to this certificate request.
DispositionMessage	Message accompanying the disposition value returned by the CA.
RenewedCertStores	List of certstores that had a certificate addition job scheduled successfully. The certstores will be listed in the format "<Store machine >-<Store path>".

Example Request

POST http://<host>/CMSApi/CertEnroll/3/Renew HTTP/1.1

```
{
       "Lookup": {"Type" : "CMSID", "CMSID" : 7},
       "CertStores": ["&lt;Guid&gt;"],
       "Template": "UserServer",
       "CAConfiguration" : "CA1.jdk.com\\jdk-CA1",
       "Metadata":{"Email-Contact":"a.b@example.com"}
}
```

Example Response

```
{
"RenewedCertStores": ["192.168.41.171-/home/pi/cherry/cherrystore"],
"Thumbprint": "46CCE7023bce5c434f4206b74473fd614df56218",
"CMSRequestId": 0,
"RequestDisposition": "Issued",
"DispositionMessage": "The certificate renewal has been completed successfully. Agent jobs to install
the new certificate have been created."
}
```

3.3.4 Certificates

The Certificates component of the Web API supports certificate lifecycle and management tasks apart from enrollment. The complete set of methods in this component is given in Table 683: Certificates Endpoints.

Table 683: Certificates Endpoints

Endpoint	Method	Description
/3/Contents	POST	Return the certificate contents in PEM format

Endpoint	Method	Description
/3/Count	POST	Return the number of certificates in the Keyfactor Command database matching a given search query
/1/Metafield	POST	Associate a metadata value with a certificate in the Keyfactor Command database.
/2/Import	POST	Add an existing certificate into the Keyfactor Command database.
/3/Revoke	POST	Revoke a given certificate.
/3/Recover	POST	Recover a given certificate
/3/PublishCRL	POST	Request a CA to publish a new CRL
/3/Search	POST	Return the full set of certificates in the Keyfactor Command database matching a given search query

3.3.4.1 Certificates Metafield

The metafield POST method is used to import individual certificate metadata field values into Keyfactor Command. This method offers limited functionality and security measures compared to the Metadata v2 and v3 methods described in the Metadata section (see Metadata on page 2160), but is included for backward-compatibility. A JSON string must be submitted with the POST request containing the data shown in Table 684: POST /1/Metafield Request Body. This method returns HTTP 200 OK with message body "true" on success or an appropriate 4xx status with an accompanying error message in the body on failure.

Table 684: POST /1/Metafield Request Body

Parameter Name	Parameter Value
CertificateId	The Keyfactor Command database row identifier associated with the existing certificate. Many times this will be the certificate id returned by the import API call.
MetadataFieldTypeName	The string name of the metadata field type for which the value is provided.
Value	The metadata field value to be associated with the provided certificate identifier.

Example Request

POST http://<host>/CMSApi/Certificates/1/Metafield HTTP/1.1

```
{
       "CertificateId": 1,
       "MetadataFieldTypeName": "Email-Contact",
       "Value": "support@example.com"
}
```

3.3.4.2 Certificates Import

The certificate import POST method is used to import a certificate (.cer) file into Keyfactor Command while also allowing the simultaneous definition of metadata values for the imported certificate. The POST request must contain a JSON string containing the certificate and any metadata items that should be associated with the certificate but does not require the content-disposition or multi-part form found in version 1. This method returns HTTP 200 OK with message body "true" on success or an appropriate 4xx status with an accompanying error message in the body on failure.

Important: Support for version 1 of the Classic API certificate import method (Certificates/1/Import) will end in an upcoming release of the product. All applications should be migrated to a newer Import endpoint.

Table 685: POST /2/Import Request Body

<table>
<tr><th>Parameter Name</th><th>Parameter Value</th></tr>
<tr><td>X509Base64</td><td>String containing the certificate blob. This may include the "-----BEGIN CERTIFICATE-----" and "-----END CERTIFICATE-----" references or these may be left out.</td></tr>
<tr><td>MetadataList</td><td>A comma-delimited list of metadata fields, each containing two parts:
<table><tr><th>Name</th><th>Description</th></tr><tr><td>MetadataFieldTypeName</td><td>The metadata field name—e.g. Email-Address</td></tr><tr><td>Value</td><td>The metadata value—e.g. bob.smith@example.com</td></tr></table>The metadataList parameter is not required, but if you choose to include it, you must include both the name and the value for each metadata value to be imported.</td></tr>
<tr><td>CertState</td><td>Used to manually set the state of the imported certificate. The following values are accepted:</td></tr>
</table>

Parameter Name	Parameter Value

Value	Description
0	Unknown
1	Active
2	Revoked
3	Denied
4	Failed
5	Pending
6	Certificate Authority
7	Parent Certificate Authority

Example Request

POST http://<host>/CMSApi/Certificates/2/Import HTTP/1.1

```
{
       "x509Base64": "-----BEGIN CERTIFICATE-----
       <base64-encoded-certificate-contents>
       -----END CERTIFICATE-----",
       "MetadataList":[
              {"MetadataFieldTypeName": "Email-Contact",
              "Value":"john.doe@example.com"}
       ]
}
```

3.3.4.3 Certificates Contents

The Contents method retrieves the contents of a specified certificate. The request requires only enough information to identify a certificate in Keyfactor Command, and the body of a successful response will consist solely of the PEM-encoded representation of that certificate. Unlike most methods, for successful requests the response content type will be "text/plain".

Table 686: POST /3/Contents Request Body

Parameter Name	Parameter Value
Lookup	Description of the certificate to be retrieved. See Table 66: Classic API Certificate Lookup Structure.

Example Request

POST http://<host>/CMSApi/Certificates/3/Contents HTTP/1.1

```
{
       "Lookup": {"type": "CMSID", "CMSID": <cms-certificate-id>}
}
```

Example Response

```
<base64-encoded-certificate-contents>
```

3.3.4.4 Certificates PublishCRL

The PublishCRL method will cause Keyfactor Command to make a request to the provided Certificate Authority to publish a new CRL to the locations configured by the CA. This method requires only a single parameter and returns no response body on a successful request. On an unsuccessful request, an appropriate HTTP status code along with a string in the response body describing the error is returned.

Table 687: POST /3/PublishCRL Request Body

Parameter Name	Parameter Value
CertificateAuthority	Certificate authority for the new CRL, in the form "hostname\\logical name" (double-backslash required for JSON formatting).

Example Request

POST http://<host>/CMSApi/Certificates/3/PublishCRL HTTP/1.1

```
{
       "CertificateAuthority" : "CA1.corp.com\\Issuing-CA1"
}
```

3.3.4.5 Certificates Recover

The Recover method allows a user to recover an archived private key for an issued certificate. For recovery to succeed, the CA that issued the certificate must have been configured to archive the private key, and the Key Recovery Agent certificate must be imported into the personal certificate store of the Keyfactor Command API IIS Application Pool's user account on the Keyfactor Command API server. If successful, the method will return the certificate and recovered private key as a base64-encoded PFX file. On error, an appropriate HTTP status code and message will be returned. See Configuring Key Recovery for Keyfactor Command on page 698 in the *Keyfactor Command Reference Guide* for information about configuring key recovery.

Table 688: POST /3/Recover Request Body

Parameter Name	Parameter Value
Lookup	Description of the certificate to be renewed. See Table 66: Classic API Certificate Lookup Structure.
Details	Information to complete the recovery operation. This contains just a single field: **Parameter Name** / **Parameter Value** Password / Password for the archived private key.

Example Request

POST http://<host>/CMSApi/Certificates/3/Recover HTTP/1.1

```
{
       "Lookup" : {"Type" : "CMSID", "CMSID" : 248852},
       "Details": {"Password": "MyPassword1234"}
}
```

Example Response

```
{
       "pfx" : "<PEM-encoded pfx>"
}
```

3.3.4.6 Certificates Revoke

The Revoke method will attempt to revoke a certificate stored in Keyfactor Command. The certificate to be revoked can be identified using the *lookup* request body parameter (see Table 66: Classic API Certificate Lookup Structure). In addition, the message may contain string parameters describing the revocation. Caution is advised when programmatically revoking certificates as the operation generally cannot be undone. The method returns a 200 OK response if successful or an appropriate HTTP code and error message if unsuccessful.

Table 689: POST /3/Revoke Request Body

Parameter Name	Parameter Value
Lookup	Criteria to specify the certificate to be revoked. See Table 66: Classic API Certificate Lookup Structure.
Details	Details used to define the revocation operation. See Table 690: Certificate Revocation Details.

Table 690: Certificate Revocation Details

Parameter Name	Parameter Value
Reason	Integer code for certificate revocation reason, as per IETF RFC 5280 ReasonFlags. This field is optional and will default to "0" (zero - unspecified). Allowed values are listed below: **Value** / **Definition** 0 / Unspecified 1 / Key Compromised 2 / CA Compromised 3 / Affiliation Changed 4 / Superseded 5 / Cessation of Operation 6 / Certificate Hold
Comment	Explanation of revocation reason. Optional and will default to the empty string "".
EffectiveDate	Date on which the revocation will take effect. Optional and will default to the current time if not specified.
noCRL	If provided and set to "true", Keyfactor Command will not attempt to have the CA publish a new CRL. Optional and treated as "false" by default.

Example Request

POST http://<host>/CMSApi/Certificates/3/Revoke HTTP/1.1

```
{
       "Lookup": {"Type": "CMSID", "CMSID": 45},
       "Details": {"Reason":4, "EffectiveDate" : "2017-12-29", "Comment": "Reissued 12-27"}
}
```

3.3.4.7 Certificates Search and Count

The Search method will return the set of certificates known to Keyfactor Command that satisfy certain criteria. The criteria that can be searched on and the syntax by which queries are formed is the same as in the Advanced Certificate Search within the Keyfactor Command Management Portal. This is largely consistent with PowerShell comparison notation, but Keyfactor does not publish a complete specification of this query language. Instead, developers are encouraged to examine the query strings formed in the Keyfactor Command Management Portal and model their API queries based on this. The response will contain a JSON body with an array whose entries each represent a single matching certificate. The Count method expects the same parameters as the Search query but simply returns a count of the records that would be returned if the same parameters were provided to the Search endpoint. For Count, the sorting parameters will have no effect.

Table 691: POST /3/Search and /3/Count Request Body

Parameter Name	Parameter Value
IncludeRevoked	Boolean denoting if revoked certificates should be included in the search results.
IncludeExpired	Boolean denoting if expired certificates should be included in the search results.
Query	Search query criteria, as defined above.
SortField	Name of the result field by which the results should be sorted. The field must be one returned within the results. This parameter is optional and the Keyfactor Command certificate id will be used if not provided. The available fields are the same as in Table 692: POST /3/Search Response Body.
SortAscending	Boolean value denoting if the SortField should be sorted in ascending order. This parameter is optional and ascending will be used if not provided.
SkipCount	Number of records that should be skipped in the results, starting from the beginning of the records (for pagination). This field is optional and no records will be skipped if not provided.
ReturnLimit	Numeric value of the limit of records to be returned. This field is optional and 5000 will be used if not provided.

Table 692: POST /3/Search Response Body

Parameter Name	Parameter Value
Id	Certificate ID assigned by Keyfactor Command, which can be used for service chaining to other

<table>
<tr><th>Parameter Name</th><th>Parameter Value</th></tr>
<tr><td></td><td>many other Web API requests by providing this value as a CMSID in the Lookup section of the request. See Table 66: Classic API Certificate Lookup Structure.</td></tr>
<tr><td>IssuedCN</td><td>Issued Common Name</td></tr>
<tr><td>IssuedDN</td><td>Issued Distinguished Name</td></tr>
<tr><td>NotBefore</td><td>Beginning date for certificate validity</td></tr>
<tr><td>NotAfter</td><td>Ending (expiration) date for certificate validity</td></tr>
<tr><td>IssuerDN</td><td>Issuer Distinguished Name</td></tr>
<tr><td>PrincipalName</td><td>Subject Principal Name</td></tr>
<tr><td>RequesterName</td><td>Requester Name</td></tr>
<tr><td>TemplateName</td><td>Certificate Template Name</td></tr>
<tr><td>CertState</td><td>Certificate State. Will take one of the following values:
<table>
<tr><th>Value</th><th>Definition</th></tr>
<tr><td>0</td><td>Unknown</td></tr>
<tr><td>1</td><td>Active</td></tr>
<tr><td>2</td><td>Revoked</td></tr>
<tr><td>3</td><td>Denied</td></tr>
<tr><td>4</td><td>Failed</td></tr>

<tr><td>Thumbprint</td><td>The hexadecimal thumbprint of the certificate.</td></tr>
</table>

Example Request

POST http://<host>/CMSApi/Certificates/3/Search HTTP/1.1

```
{
       "includeRevoked": true,
       "includeExpired": true,
       "query": "(ExpirationDate -eq \"2018-05-10\")"
}
```

Example Response

```
[{
       "Id":<certificate-id>,
       "IssuedCN": "<cn>",
       "IssuedDN": "<dn>",
       "NotBefore": "2017-05-10T18:59:57",
       "NotAfter": "2018-05-10T18:59:57",
       "IssuerDN": "<issuer-dn>",
       "PrincipalName": null,
       "RequesterName": null,
       "TemplateName": null,
       "CertState": 0,
       "KeySize": 4096,
       "KeyType": 1
}]
```

3.3.5 Certstore

The Certstore Web API (formerly known as the Jks API) provides a set of methods to support management of certificate locations. Keyfactor Command currently supports management of certificates in the following remote locations:

- Java Keystore
- PEM file
- F5 BigIP Web Server
- F5 BigIP SSL Profiles
- Windows Machine Personal, Revoked, and Trusted Roots stores
- Citrix NetScaler virtual servers

Keyfactor Command can, through different Keyfactor Command Agents and Orchestrators, inventory, install, and remove certificates for each of these store types. For certain store types, additional actions are supported as well. The certstore API provides a way to programmatically schedule jobs for these stores. For more information about certificate stores and their support within Keyfactor Command, see the Reference Guide on page 2 and Installing Orchestrators on page 2355 guide, or contact your Keyfactor representative. This API component currently has only one version, but for backward-compatibility, it can be accessed through the component name "Certstore" (e.g. /CMSApi/Certstore/1/AddCert) or the legacy name "Jks" (e.g. /CMSApi/Jks/1/AddCert). The set of methods in this API component that can be used to manage certificate stores and their scheduled jobs is listed below in Table 693: Certstore Endpoints.

Table 693: Certstore Endpoints

Endpoint	Method	Description
AddCert	POST	Add given certificate (without private key) to a given certificate store (as well as Keyfactor Command)
AddCertStore	POST	Define a new certstore in Keyfactor Command
AddCertStoreServer	POST	Define a new remote server (e.g. F5, NetScaler) in Keyfactor Command to be managed by a Keyfactor Command agent
AddPFX	POST	Add a PFX file (with private key) to a given certificate store (as well as Keyfactor Command)
AddCertStoreType	POST	Add a Certificate Store Type to be used by a certificate store
CreateJKS	POST	Create a Java Keystore on the file system on target machine
EditCertStore	POST	Update a definition of an existing certificate store in Keyfactor Command
EditCertStoreServer	POST	Update a definition of an existing remote server managed by a Keyfactor Command agent

Endpoint	Method	Description
GetCertStoreTypes	GET	List all certificate store types
Inventory	POST	Retrieve the inventory of a given certificate store
Keystores	GET	Get a list of certificate stores defined in Keyfactor Command
Remove	POST	Remove a certificate from a certificate store
ScheduleInventory	POST	Schedule a certificate store inventory job schedule
ScheduleJob	POST	Schedule a certificate store management job
Status	GET	A synonym for GET /Status, included on this path for backwards-compatibility

3.3.5.1 CertStore AddCert

The POST AddCert method will schedule the addition of the provided certificate to the specified alias/name within the provided certificate stores. The request and response objects will contain the fields shown in Table 694: POST /AddCert Request Body and Table 695: POST /AddCert Response Body.

Table 694: POST /AddCert Request Body

Parameter Name	Parameter Value
Keystores	Array of the certificate stores to which the provided entry should be added, with the same format as the response to GET /Keystores (see Table 709: GET /Keystores Response Body).
Alias	Name of the entry to which the certificate should be added. This parameter can also take a list of Certificate Store Type and Alias entries. If just a name is given, the certificate will have the same alias in all certificate stores it is added to. If a list is given, the certificate will have the same alias for each given store with the same certificate store type.
Overwrite	Boolean denoting if the entry should be overwritten, if one exists. An error will be returned if this is set to false, and an entry with the same alias/name exists.
Contents	PEM of the certificate to be added. This field is optional if a CertificateId is provided.
CertificateId	Database identifier within Keyfactor Command of the certificate to be added. This field is optional if the Contents are provided.

Table 695: POST /AddCert Response Body

Parameter Name	Parameter Value
Result	Numerical code indicating the result of the operation, as described in Table 699: POST /AddCertStoreServer Response Body.
Message	Description of the result of the operation, e.g. "The operation completed successfully".
InvalidKeystores	Array of certstores provided in the request for which the operation could not be completed. Entries will be formatted as follows:

Parameter Name	Parameter Value
KeystoreId	Guid of the certstore
ClientMachine	Machine hosting the certstore
StorePath	File path to the store on its machine
Alias	Alias for certificate to be added
Reason	Numerical code for the failure. Will take one of the following values:

Value	Error Message
0	The certificate store was not found.
1	A job to add this certificate to this alias already exists.
2	No agent is available to perform this job.

Explanation	A description of the failure encountered.

Example Request

Multiple Alias entries

POST http://<host>/CMSApi/CertStore/1/AddCert HTTP/1.1

```
{
       "Keystores":
       [
       {"Id": "", "ClientMachine": "<client-machine>", "StorePath": "<store-path>"},
       {"Id": "", "ClientMachine": "<client-machine>", "StorePath": "<store-path>"}
       ],
```

```
       "Alias": {"<store type Id>":"<alias>","<store type Id":"alias"}
       "Overwrite": true,
       "CertificateId": "<certificate-id>",
       "Contents":  "-----BEGIN CERTIFICATE-----
       <base64-encoded-certificate-contents>
       -----END CERTIFICATE-----"
}
```

Example Request

String Alias

POST http://<host>/CMSApi/CertStore/1/AddCert HTTP/1.1

```
{
       "Keystores":
       [
       {"Id": "", "ClientMachine": "<client-machine>", "StorePath": "<store-path>"},
       {"Id": "", "ClientMachine": "<client-machine>", "StorePath": "<store-path>"}
       ],
       "Alias": "<alias>",
       "Overwrite":true,
       "CertificateId":"<certificate-id>",
       "Contents": "-----BEGIN CERTIFICATE-----
       <base64-encoded-certificate-contents>
       -----END CERTIFICATE-----"
}
```

Example Response

```
{
       "Result": 1,
       "Message" : "The operation completed successfully.",
       "InvalidKeystores": []
}
```

3.3.5.2 CertStore AddCertStore

The AddCertStore method allows a client to define a new certificate store within Keyfactor Command. The structure is as follows:

Table 696: POST /AddCertStore Request Body

<table>
<tr><th>Parameter Name</th><th>Parameter Value</th></tr>
<tr><td>StoreType</td><td>Type of certificate store to be defined. This field is required and allowed values are:
<table>
<tr><th>Parameter Name</th><th>Parameter Value</th></tr>
<tr><td>0</td><td>Java Keystore</td></tr>
<tr><td>2</td><td>PEM file</td></tr>
<tr><td>3</td><td>F5 SSL Profiles</td></tr>
<tr><td>4</td><td>IIS Trusted Root Certificates</td></tr>
<tr><td>5</td><td>NetScaler</td></tr>
<tr><td>6</td><td>IIS Personal Certificates</td></tr>
<tr><td>7</td><td>F5 Web Server</td></tr>
<tr><td>8</td><td>IIS Revoked Certificates</td></tr>
<tr><td>100</td><td>Amazon Web Services</td></tr>
<tr><td>101</td><td>File Transfer Protocol</td></tr>
</table></td></tr>
<tr><td>ClientMachine</td><td>Machine where the certificate store resides (or will reside). Required.</td></tr>
<tr><td>StorePath</td><td>Path on the client machine where the store should be defined. Required for Java Keystore, PEM file, F5 SSL Profiles, and NetScaler (categories 0, 2, 3, and 5).</td></tr>
<tr><td>AgentId</td><td>Identifier of agent that will service the request. Either AgentId or AgentName must be provided for F5 (categories 3 and 7), IIS (categories 4, 6, and 8), and NetScaler stores (category 5).</td></tr>
<tr><td>AgentName</td><td>Machine name of agent that will service the request. Either AgentId or AgentName must be provided for F5 (categories 3 and 7), IIS (categories 4, 6, and 8), and NetScaler stores (category 5).</td></tr>
<tr><td>Container</td><td>Certificate store container that should contain the certificate store. This is optional and no certstore container will be assigned if it is not provided. See the Keyfactor Command Reference Guide for information on certificate store containers.</td></tr>
<tr><td>Password</td><td>Password used to access the store. Required for Java Keystore and optional for PEM file.</td></tr>
<tr><td>PrivateKeyPath</td><td>Path on the client machine where the private key should be stored. Supported only for PEM files, and is optional in that case. If no path is provided for a PEM file, the private key will be stored in the same PEM file as the certificate.</td></tr>
</table>

Table 697: POST /AddCertStore Response Body

Parameter Name	Parameter Value
Message	Description of the result of the operation, e.g. "The operation completed successfully".
Result	Numerical code for the outcome of the operation, as given in Table 699: POST /AddCertStoreServer Response Body.
Id	GUID of the created store, if successful.

Example Request

POST http://<host>/CMSApi/CertStore/1/AddCertStore HTTP/1.1

```
{
	"ClientMachine": "192.168.41.171",
	"StorePath": "/opt/cms-java-agent/config/trust.jks",
	"StoreType": 0,
	"Password": "changeit"
}
```

Example Response

```
{
	"Result": 1,
	"Message": "The operation completed successfully.",
	"Id": "b195c1f9-1957-4bdb-a15d-f45159482611"
}
```

3.3.5.3 CertStore AddCertStoreServer

Some certificate stores are managed by agents accessing the store through a third-party Web API. This currently includes F5 BigIP devices and Citrix NetScaler devices. These stores require the definition of a certstore server before the store itself can be defined in Keyfactor Command. Each server can be configured with a location and user credentials to access the client machine via the appropriate third-party API. This Keyfactor Command Web API method allows such configuration. The structure shown in Table 698: POST /AddCertStoreServer Request Body should be used for requests.

Table 698: POST /AddCertStoreServer Request Body

Parameter Name	Parameter Value
Name	Hostname of the machine the agent will connect to.
ServerType	Platform for this server, defining what certstore types are supported. Allowed values are: **Parameter Name** / **Parameter Value** 0 / F5 1 / NetScaler
UseSSL	Boolean denoting whether the agent should connect to the client API using https or http.
Username	Username to provide to the client API.
Password	Password corresponding to the login for the given Username to access the client API.

Table 699: POST /AddCertStoreServer Response Body

Parameter Name	Parameter Value
Result	Status code for the operation. Will take one of the following values: **Value** / **Description** 1 / Success 2 / Failure 3 / Warning
Message	Description of the operation outcome, e.g. "The operation completed successfully".

Example Request

POST http://<host>/CMSApi/CertStore/1/AddCertStoreServer HTTP/1.1

```
{
       "Name": "192.168.23.100",
       "UseSSL" : true,
       "Username": "nsroot",
       "Password": "nsroot",
```

```
        "ServerType": 1
}
```

Example Response

```
{
        "Result": 1,
        "Message": "The operation completed successfully."
}
```

3.3.5.4 CertStore AddCertStoreType

The POST /AddCertStoreType method will create a certificate store type that will be used for a custom certificate store that extends the Keyfactor Command Agent's Any Agent functionality. The parameters that can be used for this endpoint are shown in Table 700: POST /AddCertStoreType Request Body, while the response format can be found in Table 701: POST /AddCertStoreType Response Body.

Table 700: POST /AddCertStoreType Request Body

Parameter Name	Parameter Value
Name	The name the certificate store type will have in Keyfactor Command. This parameter is **required**.
ShortName	The short name of the certificate store type. This parameter is **required**.
AddSupported	A Boolean that sets if the certificate store of this certificate store type is allowed to be added to. This parameter is **required**.
CreateSupported	A Boolean that sets if the certificate store of this certificate store type is allowed to be created if missing. This parameter is **required**.
DiscoverySupported	A Boolean that sets if the certificate store of this certificate store type is allowed to be discovered in a discovery scan. This parameter is **required**.
RemoveSupported	A Boolean that sets if the certificate store of this certificate store type allows certificates to be removed from it. This parameter is **required**.
EnrollmentSupported	A Boolean that sets if the certificate store of this certificate store type supports reenrollment. This parameter is **required**.
EntryPasswordSupported	A Boolean that sets if the certificate store of this certificate store type supports an entry password. This parameter is **required**.
PrivateKeyAllowed	A parameter that sets requirements on the private key of a certificate being entered into

<table>
<tr><th>Parameter Name</th><th>Parameter Value</th></tr>
<tr><td></td><td>the certificate store. This parameter is required. Valid values are:<table><tr><th>Value</th><th>Name</th></tr><tr><td>0</td><td>Forbidden</td></tr><tr><td>1</td><td>Optional</td></tr><tr><td>2</td><td>Required</td></tr></table></td></tr>
<tr><td>LocalStore</td><td>A Boolean that sets if the certificate store of this certificate store type requires a certificate store server. This parameter is required.</td></tr>
<tr><td>StorePasswordRequired</td><td>A Boolean that sets if the certificate store of this type requires a password. This parameter is required.</td></tr>
<tr><td>StorePathType</td><td>The type used for the certificate store path.<table><tr><th>Option</th><th>Description</th></tr><tr><td>Empty</td><td>Path will be a free form field.</td></tr><tr><td>String</td><td>Path will only be the specified string.</td></tr><tr><td>Comma Separated String</td><td>Path will need to be chosen from the list given.</td></tr></table></td></tr>
<tr><td>CustomAliasAllowed</td><td>A Boolean that sets whether the certificate store of this type allows a custom alias. This parameter is optional.</td></tr>
<tr><td>Powershell</td><td>A Boolean that sets whether the certificate store of this type uses PowerShell. This parameter is optional.</td></tr>
<tr><td>ServerRegistration</td><td>A Boolean that sets whether Keyfactor Command needs to prompt for credentials for each client machine that has that certificate store type. This parameter is optional.</td></tr>
<tr><td>JobProperties</td><td>A comma separated string defining properties that are required when performing management jobs on a certificate store of this type. This parameter is optional.</td></tr>
<tr><td>Properties</td><td>A dictionary of any extra properties a certificate store of this type would need. This parameter is optional. If this property is provided, a type is required. Parameters of a property are:</td></tr>
</table>

Parameter Name	Parameter Value
	<table><tr><th>Field</th><th>Description</th></tr><tr><td>DisplayName</td><td>The name of the property. This parameter is optional.</td></tr><tr><td>Type</td><td>The type of the property. This parameter is **required**. Valid values are: String, Bool, MC, and Secret</td></tr><tr><td>Required</td><td>A Boolean that sets whether the property is required in the certificate store.</td></tr><tr><td>Depends</td><td>If this is not the first property, this property can depend on another property. The property name is used to determine which property is being depended on.</td></tr><tr><td>Value</td><td>A default Value of the property.</td></tr></table>

Table 701: POST /AddCertStoreType Response Body

Parameter Name	Parameter Value
Message	Description of the operation outcome, e.g. "The operation completed successfully".
Result	Status code for the operation. Will take one of the following values:<table><tr><th>Value</th><th>Description</th></tr><tr><td>1</td><td>Success</td></tr><tr><td>2</td><td>Failure</td></tr><tr><td>3</td><td>Warning</td></tr></table>
Data	<table><tr><th>Value</th><th>Description</th></tr><tr><td>Name</td><td>The name of the type.</td></tr><tr><td>ShortName</td><td>The ShortName of the type.</td></tr><tr><td>StoreType</td><td>The Id of the store</td></tr><tr><td>LocalStore</td><td>A Boolean if the certificate store is on the local server of the agent.</td></tr></table>

Parameter Name	Parameter Value

Value	Description
ServerRegistration	Tells whether server registration is needed by Keyfactor Command.
ImportType	A value to indicate the source of a certificate record in the Keyfactor Command audit logs.
InventoryJobType	The GUID of the inventory job type that is used to register with the Any Agent.
ManagementJobType	The GUID of the management job type that is used to register with the Any Agent.
AddSupported	A Boolean stating whether an add job will be supported by the certificate store.
RemoveSupported	A Boolean stating whether a remove job will be supported by the certificate store.
CreateSupported	A Boolean stating whether a create job will be supported by the certificate store.
DiscoverySupported	A Boolean stating whether a discovery job will be supported by the certificate store.
EnrollmentSupported	A Boolean stating whether an enrollment job will be supported by the certificate store.
InventoryEndpoint	The endpoint that will be hit by the agent.
Properties	A list of properties that reflect those given in the request.
EntryPasswordSupported	A Boolean stating whether an entry password will be supported by the certificate store.
StorePasswordRequired	A Boolean stating whether a store password will be required by the certificate store.
PrivatekeyAllowed	An integer notifying the state of the private keys in the certificate store.

<table>
<tr><th>Parameter Name</th><th>Parameter Value</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Name</th></tr>
<tr><td>0</td><td>Forbidden</td></tr>
<tr><td>1</td><td>Optional</td></tr>
<tr><td>2</td><td>Required</td></tr>
</table>
</td></tr>
<tr><td>StorePathType</td><td>The value of the store path. If value is an empty string, the field is free form.</td></tr>
<tr><td>CustomAliasAllowed</td><td>A Boolean stating whether a custom alias will be supported by the certificate store.</td></tr>
<tr><td>JobProperties</td><td>The properties that will be required when performing a management job on the certificate store with this type.</td></tr>
</table>
</td></tr>
</table>

Example Request

POST http://<host>/CMSApi/CertStore/1/AddCertStoreType HTTP/1.1

```
{
       "Name": "<Type Name>",
       "ShortName": "<Type Short Name>",
       "AddSupported": true,
       "CreateSupported": false,
       "DiscoverySupported": true,
       "RemoveSupported": true,
       "EnrollmentSupported": true,
       "EntryPasswordSupported": true,
       "PrivateKeyAllowed": <integer 0-2>,
       "LocalStore": true,
       "StorePasswordRequired": true,
       "Powershell":false,
       "CustomAliasAllowed":false,
       "JobProperties":"<List of Job Properties>",
       "ServerRegistration": false,
       "Properties": {
              “<Property Name>": {
                     "type":"<Property Type>",
```

```
                        “DisplayName”: “<Discplay Name>”
                },
                "<Property Name>":{
                        "type":"<Type>",
                        “displayName”:”<Display Name>”
                        "value": "<Value>"
                }
        },
        "StorePathType": <Path Type>
}
```

Example Response

Status Code: 200

```
{
        "Message": "The operation completed successfully.”,
        "Result": 1,
        "Data": {
                "Name": "<Name>",
                "ShortName": "<Short Name>",
                "StoreType": <Store Type Id>,
                "LocalStore": true,
                "ServerRegistration": null,
                "ImportType": <Import Type>,
                "InventoryJobType": "<Inventory Job Type Guid>",
                "ManagementJobType": "<Management Job Type Guid>",
                "AddSupported": false,
                "RemoveSupported": true,
                "CreateSupported": false,
                "DiscoveryJobType": "<Discovery Job Type Guid>",
                "EnrollmentJobType": "<Enrollment Job Type Guid>",
                "InventoryEndpoint": “<Inventory Endpoint>",
                "Properties": {
                        "<Property Name>": {
                                "Type": "<Type>",
                                "DisplayName": "<Discplay Name>",
                                "Required": false,
                                "Depends": null,
                                "Value": <Value>
                        },
                        "<Property Name>": {
                                "Type": "<Type>",
                                "DisplayName": “<Display Name> ",
```

```
                            "Required": false,
                            "Depends": null,
                            "Value": "<Value>"
                        }
                },
                "EntryPasswordSupported": true,
                "StorePasswordRequired": true,
                "PrivateKeyAllowed": <Integer 0-2>,
                "StorePathType": <Store Path Type>,
                "CustomAliasAllowed": false,
                "JobProperties": "<Job Properties>"
        }
}
```

3.3.5.5 CertStore AddPFX

The POST AddPfx method will schedule the addition of the provided PFX(s) to the specified alias/name within the provided certificate store(s). The request should contain the fields shown in Table 702: POST /AddPfx Request Body, while the response format will be the same as for AddCert (see Table 695: POST /AddCert Response Body).

Table 702: POST /AddPfx Request Body

Parameter Name	Parameter Value
Keystores	Array of certificate stores to which the provided entry should be added, with the same format as the response to GET /Keystores (see Table 709: GET /Keystores Response Body).
Alias	Name of the entry to which the certificate should be added.
Overwrite	Boolean denoting if the entry should be overwritten, if one exists. An error will be returned if this is set to false but an entry with the same alias/name exists.
Contents	PEM of the PFX to be added. Do not include the …BEGIN… AND …END… lines.
PfxPassword	Password of the PFX.
HasEntryPassword	Boolean denoting if the password required for the entry is different than that of the certificate store itself.
EntryPassword	Password for the certificate store entry. Required if the HasEntryPassword is set to true.

Example Request

POST http://<host>/CMSApi/CertStore/1/AddPfx HTTP/1.1

```
{
       "Keystores":
       [{
       "Id": "<keystore-id>",
       "ClientMachine": "<client-machine>",
       "StorePath": "<store-path>"
       },
       {
       "Id": "<keystore-id>",
       "ClientMachine": "<client-machine>",
       "StorePath": "<store-path>"
       }],
       "Alias": "<alias>",
       "Overwrite": "true",
       "HasEntryPassword": "true",
       "EntryPassword": "<entry-password>",
       "PfxPassword": "<pfx-password>",
       "Contents": "<base64-encoded PFX>"
}
```

3.3.5.6 CertStore CreateJKS

In most cases, certificate stores will already exist on the client machine prior to configuration within Keyfactor Command. For example, the IIS Personal Store exists on each windows machine independently of Keyfactor Command installation. In other cases, such as PEM files, the file can be created when a certificate is added. However, with a Java Keystore, creating the store on the file system and adding certificates to it are different operations. The CreateJKS method supports scheduling creation of a Java Keystore as a Keyfactor Command Agent job. The structure of this request is given in Table 703: POST /CreateJKS Request Body while the response is the same as for AddCertStore (see Table 697: POST /AddCertStore Response Body).

Table 703: POST /CreateJKS Request Body

Parameter Name	Parameter Value
ClientMachine	Machine on which the certificate store will reside.
StorePath	Path and filename of the certificate store to be created.
Password	Password to use for the new store.

Example Request

POST http://<host>/CMSApi/CertStore/1/CreateJKS HTTP/1.1

```
{
       "ClientMachine" : "192.168.41.171",
       "StorePath" : "/opt/cms-java-agent/config/trust.jks",
       "Password" : "changeit"
}
```

3.3.5.7 CertStore EditCertStore

The EditCertStore method allows certain aspects of a cert store definition to be updated. Some aspects, such as the store type and client machine, cannot be updated. The format of the request given in Table 704: POST /EditCertStore Request Body, while the response will be as it is for Table 699: POST /AddCertStoreServer Response Body.

Table 704: POST /EditCertStore Request Body

Parameter Name	Parameter Value
Id	Guid – Unique identifier of the certificate store. This field is the most specific, and does not require either the ClientMachine or StorePath fields to be provided.
ClientMachine	Machine on which the store resides. This field is required if the Id field is not provided.
StorePath	Path and filename of the certificate store. This field is required if the Id field is not provided.
NewStorePath	New path on the machine filesystem where the certstore resides.
NewContainer	Reassign the certstore container in Keyfactor Command where this store is configured.
NewPassword	Change the password used by the agent to access the store.
NewPrivateKeyPath	Change the path of a private key stored separately from a PEM file certificate
NewAgentId	Change the agent managing a remote certstore by providing its GUID. Cannot be used with NewAgentName.
NewAgentName	Change the agent managing a remote certstore by providing the name it reports to Keyfactor Command. Cannot be used with NewAgentId.

Example Request

POST http://<host>/CMSApi/CertStore/1/EditCertStore HTTP/1.1

```
{
       "ClientMachine": "192.168.23.100",
       "StorePath" : "/nsconfig/ssl",
       "NewStorePath" : "/nsconfig/ssl/vserver1",
```

```
        "NewContainer": "NetScaler"
}
```

3.3.5.8 CertStore EditCertStoreServer

A cert store server is a machine that hosts a store that is remotely managed by a Keyfactor Command Agent, such as a NetScaler or F5 device. The CertStoreServer configuration contains the data that allows the agent to connect to the host via the host platform's API. This method allows configuration of an existing CertStoreServer to be updated. The request format is shown in Table 705: POST /EditCertStoreServer Request Body, while the response format is the same as for AddCertStoreServer (see Table 699: POST /AddCertStoreServer Response Body).

Table 705: POST /EditCertStoreServer Request Body

Parameter Name	Parameter Value
Name	Hostname of the machine the agent will connect to. Required if Id is not provided.
Id	Identifier of the certstore server to update. Required if Name is not provided.
UseSSL	Boolean denoting whether the agent should connect to the client API using https or http.
NewUsername	Username to provide to the client API. Required if NewPassword is provided.
NewPassword	Password corresponding to the login for the given Username to access the client API. Required if NewUsername is provided.

Example Request

POST http://<host>/CMSApi/CertStore/1/EditCertStoreServer HTTP/1.1

```
{
        "Name": "192.168.23.100",
        "UseSSL" : true,
        "newUsername" : "myNetScalerAdmin",
        "newPassword": "S1deways-Grassh0pper4979"
}
```

3.3.5.9 CertStore GetCertStoreTypes

The GET CertStoreTypes method returns a list of all certificate store types. The format for each element in the list can be found in Table 706: GET /GetCertStoreTypes Response Body.

Table 706: GET /GetCertStoreTypes Response Body

Parameter Name	Parameter Value
Name	The name of the type.
ShortName	The short name of the type.
StoreType	The Id of the type.
LocalServer	A Boolean stating if the certificate store server is the same machine as the agent.
ServerRegistration	A Boolean stating whether Keyfactor Command needs to prompt for credentials for each client machine that has this certificate store type.
InventoryJobType	The GUID of the Inventory Job.
ManagementJobType	The GUID of the management job.
DiscoveryJobType	The GUID of the discovery job.
EnrollmentJobType	The GUID of the enrollment job.
InventoryEndpoint	The server endpoint to which the agent publishes its inventory results.
Properties	The added properties of the certificate store that uses this type.
EntryPasswordSupported	A Boolean stating if an entry password is supported by the certificate store that uses this type.
StorePasswordRequired	A Boolean stating if a store password is required by the certificate store that uses this type.
PrivateKeyAllowed	A Boolean stating if a private key is allowed by the certificate store that uses this type.
StorePathType	The value for the store path. Can be null, a string or a comma-separated string for free form, the specified path or a list of paths to choose from respectively.

3.3.5.10 CertStore Inventory

The POST Inventory method returns a list of the entries within the provided certificate store. The request body is formatted the same as the response to GET /Keystores (see Table 709: GET /Keystores Response Body).

Table 707: POST /Inventory Response Body

Parameter Name	Parameter Value
Alias	Alias/name of the certificate store entry.

Parameter Name	Parameter Value
PrivateKeyEntry	Boolean value denoting if the entry has an associated private key.
Certificates	Array of the certificates contained within the certificate store (see Table 708: POST /Inventory Response Certificates Fields).

Table 708: POST /Inventory Response Certificates Fields

Parameter Name	Parameter Value
ChainLevel	Position of the certificate within the chain. This is only applicable for private key entries.
CertificateId	Database identifier of the certificate within Keyfactor Command.
Thumbprint	Thumbprint of the certificate.

Example Request

POST http://<host>/CMSApi/CertStore/1/Inventory HTTP/1.1

```
{
       "Id": "<certificate-store-id>",
       "ClientMachine": "<client-machine>",
       "StorePath": "<store-path>"
}
```

Example Response

```
[
       {
       "Alias": "<alias1>",
       "PrivateKeyEntry": false,
       "Certificates": [{"ChainLevel":0,"CertificateId":<id>,"Thumbprint":"<thumbprint>"}]
       },
       {
       "Alias": "<alias2>",
       "PrivateKeyEntry": true,
       "Certificates":
       [
       {"ChainLevel": 0,"CertificateId": <id>,"Thumbprint": "<thumbprint>"},
       {"ChainLevel": 1,"CertificateId": <id>,"Thumbprint": "<thumbprint>"},
```

```
        {"ChainLevel": 2,"CertificateId": <id>,"Thumbprint": "<thumbprint>"}
        ]
        }
]
```

3.3.5.11 CertStore Keystores

The GET Keystores method returns a list of the certificate stores within Keyfactor Command. This method requires no parameters. An array of the certificate stores is returned. The information shown in Table 709: GET /Keystores Response Body is returned for each certificate store in the array.

Table 709: GET /Keystores Response Body

Parameter Name	Parameter Value
Id	The Keyfactor Command request database identifier of the certificate store.
ClientMachine	Host name of the machine on which the certificate store resides.
StorePath	Path or other identifier of the certificate store (e.g. "IIS Personal" for IIS Personal stores).

Example Request

GET http://<host>/CMSApi/Certstore/1/Keystores

Example Response

```
[
        {
        "Id": "<certificate-store-id>",
        "ClientMachine": "<client-machine>",
        "StorePath": "<store-path>"
        },
        {
        "Id": "<certificate-store-id>",
        "ClientMachine": "<client-machine>",
        "StorePath": "<store-path>"
        }
]
```

3.3.5.12 CertStore Remove

The POST Remove method will schedule the removal of the provided entry associated with the specified alias/-name within the provided certificate store(s). The request should contain the fields shown in Table 710: POST /Remove Request Body, while the response will be formatted as it is for AddCert and AddPfx (see Table 695: POST /AddCert Response Body).

Table 710: POST /Remove Request Body

Parameter Name	Parameter Value
Keystores	Array of the certificate stores from which the provided entry should be removed, formatted as with the GET /Keystores response (see Table 709: GET /Keystores Response Body).
Alias	Name of the entry from which the certificate should be removed.
Thumbprint	Thumbprint of the certificate to be removed. This field is optional if the CertificateId is provided.
CertificateId	Database identifier within Keyfactor Command of the certificate to be removed. This field is optional if the Thumbprint is provided.

Example Request

POST http://<host>/CMSApi/CertStore/1/Remove HTTP/1.1

```
{
       "Keystores":
       [{
       "Id": "<keystore-id>",
       "ClientMachine": "<client-machine>",
       "StorePath": "<store-path>"
       },
       {
       "Id": "<keystore-id>",
       "ClientMachine": "<client-machine>",
       "StorePath": "<store-path>"
       }],
       "Alias": "<alias>",
       "CertificateId": "<certificate-id>",
       "Thumbprint": "<thumbprint>"
}
```

3.3.5.13 CertStore ScheduleInventory

Keyfactor Command Agents typically monitor the contents of cert stores they manage on a pre-configured interval, either once per day or every n minutes. The ScheduleInventory endpoint allows this interval configuration to be updated or switched on and off. Requests are formatted as follows, while the response is formatted as for AddCertStoreServer (see Table 699: POST /AddCertStoreServer Response Body):

Table 711: POST /ScheduleInventory Request Body

Parameter Name	Parameter Value
Id	Guid – Unique identifier of the certificate store. This field is the most specific, and does not require either the ClientMachine or StorePath fields to be provided.
ClientMachine	Machine on which the certificate store resides. This field is optional if the Id field is provided. It is required if used in conjunction with the ClientMachine field.
StorePath	Path and filename of the certificate store. This field is optional if the Id field is provided. It is required if used in conjunction with the ClientMachine field.
ScheduleType	Value indicating whether inventory should be off, on an interval, or daily. Possible values are: **Parameter Name** / **Parameter Value** 0 – Off 1 – Interval 2 – Daily
ScheduleTime	Time of day (hour and minute) that the inventory should run. Used for ScheduleType "Daily".
ScheduleInterval	Integer number of minutes that should elapse between inventories. Used for ScheduleType "Interval".
Overwrite	Boolean indicating whether a previous schedule configuration, if it exists, should be overwritten with the provided schedule configuration.

Example Request

POST http://<host>/CMSApi/CertStore/1/ScheduleInventory HTTP/1.1

```
{
       "ID": "832f87c7-0af7-4043-9840-3022faeeae45",
       "ClientMachine": "192.168.41.171",
       "StorePath": "/home/pi/cherry/cherrystore",
       "ScheduleType": 2,
```

```
        "ScheduleTime: "23:00",
        "Overwrite": true
}
```

Example Response

Status Code: 200

```
{
        "Message": "The operation completed successfully.",
        "Result": 1
}
```

3.3.6 Metadata

Metadata in Keyfactor Command allows dynamic information about a certificate, or other data associated with a certificate that isn't included in the cert itself, to be associated with the certificate within Keyfactor Command. A metadata field can be defined within Keyfactor Command of a given type with a variety of other attributes, such as default values and security constraints. Currently, the supported metadata types are:

- String
  Alphanumeric text field limited to 400 characters.
- Integer
  Supports whole numbers only.
- Date
- Multiple Choice
- Big Text
  Big Text fields are limited to 4000 characters. String fields support additional indexing, and so may be preferable to Big Text fields for large databases where possible.
- Boolean
  True/False

Every certificate in Keyfactor Command can be assigned a value for each metadata field defined. The Metadata Web API component supports assignment, retrieval, and comparison of metadata values associated with a certificate, as well as retrieval of metadata field definitions. The supported methods are listed in Table 712: Metadata Endpoints.

NOTE: Since the Certificates/1/Metafield endpoint (see Certificates Metafield on page 2129) is considered "Version 1" of this API component, version numbering here starts at 2.

Table 712: Metadata Endpoints

Endpoint	Method	Description
/2/Compare	POST	Compare the stored value for a metadata field associated with a given certificate against the value given in the request, and return a Boolean indicating whether the values match.
/2/Get	POST	Return the value for a metadata field associated with a given certificate.
/2/Set	POST	Assign a value for a metadata field to a given certificate.
/3/Get	POST	Return the value for a metadata field associated with a given certificate.
/3/GetDefinition	POST	Return the definition for the metadata field with given name.
/3/Set	POST	Assign a value for a metadata field to a given certificate.

3.3.6.1 Metadata V2

The *Metadata/2/…* calls all have a common request format and set of response codes. The request body is always a JSON-formatted string containing a set of fields used to identify the certificate the operation is to be performed on and a list of key-value pairs defining the metadata fields of interest. In the case of the Set method, the values to which each field should be set must also be provided.

Table 713: POST Metadata/2/ Request Body*

Parameter Name	Parameter Value
Key	The key value can either be "Thumbprint" or "Serial" to identify the certificate. If you choose serial, you must include both the SerialNumber and the IssuerDN fields.
SerialNumber	The serial number of the certificate. Required only if Key is set to "Serial".
IssuerDN	The issuer of the certificate. Required only if Key is set to "Serial".
Thumbprint	The thumbprint of the certificate. Required only if Key is set to "Thumbprint".
metadatalist	Metadata field/value entries in one of the following forms: • [{"MetadataFieldTypeName" : "<field1-name>", "Value" : "<field1-value>"}, {…}, {…}] • {"<field1-name>" : "<field1-value>", "<field2-name>" : "<field2-value>"}

Metadata V2 Set

The Metadata V2 Set POST method is used to set metadata value on a certificate in Keyfactor Command. The POST request body must consist of a JSON string containing the parameters used to set a certificate's metadata. If the

request is successful, a 200 OK will be returned with "true" in the message body. If it is not, an appropriate 4xx HTTP status code is returned, and the body will contain a JSON object with a message about the error.

Example Request

Using thumbprint

POST http://<host>/CMSApi/Metadata/2/Set

```
{
       "Key": "Thumbprint",
       "Thumbprint": "<thumbprint>",
       "metadatalist" : [{"EmailAddress":"bob.smith@example.com"}]
}
```

Example Request

Using serial

POST http://<host>/CMSApi/Metadata/2/Set HTTP/1.1

```
{
       "Key": "Serial",
       "SerialNumber": "<serial-number>",
       "SerialIssuer": "<issuing-ca>",
       "metadatalist": [{"EmailAddress": "bob.smith@example.com"}]
}
```

Example Response

(Unsuccessful)

```
{
       "Message": "The following metadata errors were found: 'myInvalidField' was not a valid
MetadataFieldTypeName."
}
```

Metadata V2 Get

The Metadata V2 Get POST method is used to get metadata value on a certificate in Keyfactor Command. Despite the "Get" in the Keyfactor Command method name, the HTTP method must be POST and not GET. As with metadata/2/set (see Metadata V2 Set on the previous page), the POST request body must consist of a JSON string

containing the parameters used to get a certificate's metadata. The "value" attribute for each entry in the metadatalist is not used, but must be present and can be set to null or an empty string.

Example Request

Using thumbprint

POST http://<host>/CMSApi/Metadata/2/Get HTTP/1.1

```
{
       "Key": "Thumbprint",
       "Thumbprint": "<thumbprint>",
       "metadatalist": [{"MetadataFieldTypeName": "EmailAddress", "Value": ""}]
}
```

Example Response

```
{
       "EmailAddress" : "bob.smith@example.com"
}
```

Metadata V2 Compare

The Metadata V2 Compare method takes a collection of metadata and returns a true/false response depending on whether the values for the fields provided match the values stored in Keyfactor Command. This can be used to prevent exposing sensitive data while still providing functionality. For example, with this method a metadata attribute can be used along with the certificate itself as a second authentication factor to third-party applications.

Example Request

POST http://<host>/CMSApi/Metadata/2/Compare HTTP/1.1

```
{
       "Key": "Thumbprint",
       "Thumbprint": <Thumbprint>
       "metadatalist": [{"MetadataFieldTypeName": "EmailAddress",
       "Value": "example@example.com"}]
}
```

3.3.6.2 Metadata V3

Version 3 of the metadata API allows more flexibility in certificate lookup and security measures than version 2, while allowing more to be done in a single API call and with a more concise JSON representation. Requests to metadata v3 API methods include 3 parts as shown in Table 714: Metadata V3 Request Body.

Table 714: Metadata V3 Request Body

Parameter Name	Parameter Value
Lookup	Given in Table 66: Classic API Certificate Lookup Structure.
Security	Given in Table 715: Metadata V3 Security Bitflags
Metadata	Dictionary of key-value pairs, where the key represents the metadata field and (for the set method) the value represents the value to be associated to the certificate referenced in the "Lookup" value. For Get and GetDefinition methods, the same structure is used but the value is not considered.

The security parameter includes a set of required flags, certain of which necessitate the inclusion of other parameters. The flags should be passed as integers, combined together using bitwise OR. The flags defined in Keyfactor Command are described in Table 715: Metadata V3 Security Bitflags.

Table 715: Metadata V3 Security Bitflags

Value	Definition
00000001	Fail if certificate has been revoked or denied.
00000010	Fail if certificate has expired.
00000100	Fail if certificate status is pending or unknown.
00001000	Fail if metadata values provided for authentication do not match the values stored in Keyfactor Command. Must be paired with an "authmetadata" field, the value of which is a dictionary formatted with {"MetadataFieldName" : "AssociatedCertificateValue" pairs}. This effectively supplants the "Compare" method found in v2.
00100000	Overwrite flag – update value even if field is configured to require explicit overwrites and a value has been associated with the certificate (applies to Set method only).

The metadata argument is a JSON dictionary containing 0 or more key-value pairs. In each pair, the key must correspond to the name of a metadata field. The value, if present, must be of a data type matching the type of the field. For Boolean and integer metadata field values, this is the JSON Boolean or integer type, respectively, while all other metadata field types are to be represented as strings. Dates should be passed in the "YYYY-M-D" format. Multi-valued entries should have a value that exactly matches one of the pre-defined values. For the Get method, values need not be provided and the empty string can be used as the value for each key. In the case where there

are 0 metadata arguments, the "Metadata" key must still be present and mapped to an empty object "{}". Note that this syntax is different than previous Metadata API versions, and uses a more concise format. An example is:

```
"Metadata" : {"Email-Contact" : "user@example.com", "Contact-Name" : "John Doe", "ID-number" : 738}
```

Metadata V3 Set

The Metadata V3 Set POST method is used to set metadata value on a certificate in Keyfactor Command. It returns a "200 OK" response with no further content on success.

Example Request

Using thumbprint

POST http://<host>/CMSApi/Metadata/3/Set HTTP/1.1

```
{
       "Lookup":
       {
              "Type": "Thumbprint",
              "Thumbprint": "<thumbprint>"
       },
       "Security": {"Flags": 3},
       "Metadata": {"Email-Contact": "bob.smith@example.com"}
}
```

Example Request

Using serial

POST http://<host>/CMSApi/Metadata/3/Set HTTP/1.1

```
{
       "Lookup":
       {
              "Type": "Serial",
              "SerialNumber": "<serial-number>",
              "IssuerDN": "<issuer-dn>"
       },
       "Security": {"Flags" : 3},
       "Metadata": {"Email-Contact": "bob.smith@example.com"}
}
```

Metadata V3 Get

The Metadata V3 Get POST method is used to get metadata value on a certificate in Keyfactor Command. Despite the "Get" in the Keyfactor Command method name, the HTTP method must be POST and not GET. As with metadata/3/set (see Metadata V3 Set on the previous page), the POST request body must consist of a JSON string containing the parameters used to get a certificate's metadata. The "value" attribute for each metadata entry is not used, but must be present and can be set to null or an empty string. The method returns a JSON dictionary in a format identical to the metadata parameter, with key-value pairs containing the fields and values requested.

Example Request

POST http://<host>/CMSApi/Metadata/3/Get HTTP/1.1

```
{
	"Lookup":
	{
		"Type": "Serial",
		"SerialNumber": "<serial-number>",
		"IssuerDN": "<issuer-dn>"
	},
	"Security": {"Flags": 3},
	"Metadata ": {"Email-Contact": ""}
}
```

Example Response

```
{
	"Email-Contact": "bob.smith@example.com"
}
```

Metadata V3 GetDefinition

The Metadata V3 GetDefinition API endpoint will return the definition of a metadata field. Note that, while this does not operate on a certificate, the same request structure is used so the fields must be supplied, but the value will not be used. The structure of the response is given below.

Table 716: POST /GetDefinition Response Body

Parameter Name	Parameter Value
Name	Name of the metadata field.

Parameter Name	Parameter Value
Description	Purpose or intended usage of the field.
Hint	Sample value to be shown when users enter a value for this field in the Keyfactor Command Management Portal.
Validation	Regular Expression string capturing acceptable values for this field.
Required	Boolean indicating whether certificates added to Keyfactor Command must include a value for this field.
Message	Error message to be returned for values that do not conform to the regular expression.
Options	Comma-separated list of allowed values for "multi-valued" metadata fields.
DefaultValue	Initial value to be assigned for new certificates if a value is not provided at addition time.
AllowAPI	Boolean indicating whether values for this field are exposed through API Get and Set requests.
ExplicitUpdate	Boolean indicating whether updates require an appropriate flag to overwrite previous values.

Example Request

POST http://<host>/CMSApi/Metadata/3/GetDefinition HTTP/1.1

```
{
       "Lookup": { "Type": "CMSID", "CMSID" : 1},
       "Security": {"Flags": 0},
       "Metadata ": {"Email-Contact": ""}
}
```

Example Response

```
{
       "Name": "Email-Contact",
       "Description": "Email contact for the certificate.",
       "Hint": "contact@domain.com",
       "Validation": null,
       "Required": false,
       "Message": null,
       "Options": null,
       "DefaultValue": null,
       "AllowAPI": true,
```

```
        "ExplicitUpdate": true
}
```

3.3.7 Security

The Security component of the Keyfactor Web APIs includes all methods necessary to programmatically add, get and delete security identities as well as get, add, edit and delete the security roles defined in Keyfactor Command. The complete set of methods in the component is given in 3.3.7 Security.

Table 717: Security Endpoints

Endpoint	Method	Description
/1/GetIdentities	GET	Return a list of the identities in Keyfactor Command, the roles they are assigned to and their validity
/1/AddIdentity	POST	Add an identity to Keyfactor Command
/1/DeleteIdentities	POST	Remove an identity from Keyfactor Command
/1/GetRoles	GET	Retrieve all the security roles currently defined in Keyfactor Command with all of their permissions, a description and who they are assigned to
/1/AddRole	POST	Add a security role to Keyfactor Command
/1/EditRole	POST	Edit a security role in Keyfactor Command
/1/DeleteRole	POST	Delete a security role from Keyfactor Command

3.3.7.1 Security GetIdentities

The GET GetIdentities request returns a list of identities known to Keyfactor Command with the type of identity (user or group), whether the identity is valid or not and the roles associated with the identity. No parameters or extra headers are necessary for this method.

Example Request

GET http://<host>/CMSApi/Security/1/GetIdentities HTTP/1.1

Example Response

Status Code: 200

```
[
	{
		"Id": <Id>,
		"AccountName": "<Domain>\\<Identity>",
		"Type": "<Identity Type>",
		"Roles": "<List of Roles>",
		"Valid": true
	}
]
```

3.3.7.2 Security AddIdentity

The POST AddIdentities request adds an identity to Keyfactor Command. The POST request must contain a JSON string containing the AD account name. This method returns a 200 with the Id, account name, type, roles, and validity of the identity. The request parameters can be found in Table 718: POST AddIdentity Request Parameter.

Table 718: POST AddIdentity Request Parameter

Parameter Name	Parameter Value
Account	The name of the account that is to be added to CMS. This parameter is required.

Example Request

For a user

POST http://<host>/CMSApi/Security/1/AddIdentity HTTP/1.1

```
{
	"Account": "<Domain>\\<User>"
}
```

Example Request

For a group

POST http://<host>/CMSApi/Security/1/AddIdentity HTTP/1.1

```
{
	"Account": "<Domain>\\<Group>"
}
```

Example Response

Status Code: 200

```
{
       "Id": <Id>,
       "AccountName": "<Domain>\\<Identity>",
       "Type": "<Identity Type>",
       "Roles": "<List of Roles>",
       "Valid": true
}
```

3.3.7.3 Security DeleteIdentity

The POST AddIdentities request removes an identity from Keyfactor Command. The POST request must contain a JSON string containing the identity Id. This method returns a 200 a message stating the identity was deleted successfully. The request parameters can be found in Table 719: POST DeleteIdentity Request Parameter

Table 719: POST DeleteIdentity Request Parameter

Parameter Name	Parameter Value
Id	The Id of the identity that is to be deleted

Example Request

POST http://<host>/CMSApi/Security/1/DeleteIdentity HTTP/1.1

```
{
       "Id": <Id>
}
```

Example Response

Status Code: 200

```
{
       "Message": "ADIdentity deleted successfully"
}
```

3.3.7.4 Security GetRoles

The GET GetRoles endpoint retrieves all the current security roles defined in Keyfactor Command and returns the Id, name, description, validity, permissions and associated identities. The response parameters can be found in

Table 720: POST /GetRoles Response Body.

Table 720: POST /GetRoles Response Body

Parameter Name	Parameter Value
Id	The Id of the security role.
Name	The name of the security role.
Description	The description of the security role.
Valid	The validity of the security role.
Permissions	The permissions of the security role.
Identities	The security identities of the security role.

Example Request

GET http://<host>/CMSApi/Security/1/GetRoles HTTP/1.1

Example Response

Status Code: 200

```
[
	{
		"Id": <Id>,
		"Name": "<Name>",
		"Description": "<Description>",
		"Valid": true,
		"Permissions": "<List of Permissions>",
		"Identities": "<List of Identities>"
	},
]
```

3.3.7.5 Security AddRole

The POST AddRole endpoint creates a security role in Keyfactor Command. This endpoint can be used to assign a role to an identity and permissions to a role.

The list of available permissions can be found in Table 721: Keyfactor Command Permissions List.

Request parameters can be found in Table 722: POST /AddRole Request Parameters.

Response parameters can be found in Table 720: POST /GetRoles Response Body.

Table 721: Keyfactor Command Permissions List

Permission Name	Permission Value
AgentAutoRegistrationModify	Permission to modify agent auto registrations.
AgentAutoRegistrationRead	Permission to read agent auto registrations.
AgentManagementModify	Permission to modify agents.
APIRead	Permission to use the Keyfactor Web APIs.
CertificateCollectionsModify	Permission to modify certificate collections.
CertificateMetadataTypesModify	Permission to modify metadatatypes.
CertificateMetadataTypesRead	Permission to read metadata types.
CertificatesImport	Permission to import certificates.
CertificatesModify	Permission to modify certificates' metadata.
CertificatesRead	Permission to read certificates.
CertificatesRecover	Permission to recover certificates.
CertificatesRevoke	Permission to revoke certificates.
CertificateStoreManagementModify	Permission to modify certificate stores.
CertificateStoreManagementRead	Permission to read certificate stores.
CertificateStoreManagementSchedule	Permission to schedule certificate stores.
MacAutoEnrollManagementModify	Permission to modify Mac auto enrollment settings.
MacAutoEnrollManagementRead	Permission to read Mac auto enrollment settings.
ManagementPortalRead	Permission to read the Keyfactor Command Management Portal.
MonitoringModify	Permission to modify monitoring settings.
MonitoringRead	Permission to read monitoring settings.
MonitoringTest	Permission to test monitoring.
PKIManagementModify	Permission to modify PKI management settings.
PKIManagementRead	Permission to read PKI management settings.
ReportsModify	Permission to modify reports.

Permission Name	Permission Value
ReportsRead	Permission to read reports.
SecuritySettingsModify	Permission to modify security settings.
SecuritySettingsRead	Permission to read security settings.
SSLManagementModify	Permission to modify SSL management settings.
SSLManagementRead	Permission to read SSL management settings.
SystemSettingsModify	Permission to modify system settings.
SystemSettingsRead	Permission to read system settings.
WorkflowModify	Permission to modify alert definitions.
WorkflowParticipate	Permission to approve/deny pending certificates.
WorkflowRead	Permission to read certificates in a pending state and alert definitions.
WorkflowTest	Permission to test alerts.

Table 722: POST /AddRole Request Parameters

Parameter Name	Parameter Value
Name	The name of the security role. This parameter is **required**.
Description	A description of the security role. This parameter is **required**.
Permissions	A list of permissions for the security role. This parameter is optional.
Identities	A list of security identities that will be associated with the security role. This parameter is optional.

Example Request

POST http://<host>/CMSApi/Security/1/AddRole

```
{
       "Name":"<Name>",
       "Description":"<Description>",
       "Permissions": ["<Permission>","<Permission>"],
```

```
        "Identities": ["<Domain>\\<Identity>", "<Domain>\\<Identity>"]
}
```

Example Response

Status Code: 200

```
{
        "Id": <Id>, “Name": "<Name>",
        "Description": "<Description>",
        "Valid": true,"Permissions": "<List of permissions>",
        "Identities": "<List of identities>"
}
```

3.3.7.6 Security EditRole

The POST EditRole endpoint modifies existing security roles. The parameters for the EditRole endpoint can be found in Table 723: POST /EditRole Request Parameters. The administrator role’s name, description and permissions cannot be changed.

Table 723: POST /EditRole Request Parameters

Parameter Name	Parameter Value
Id	The Id of the security role to be edited. This parameter is **required**.
Name	The name to which the security role will be changed. This parameter is optional.
Description	The description of which the security role will be changed. This parameter is optional.
Permissions	The permissions to which the security role will be changed. This parameter is optional.
Identities	The identities to which the security role will be changed. This parameter can take either the Id of a security identity or the identity name. This parameter is optional.

Example Request

POST http://<host>/CMSApi/Security/1/EditRole

```
{
        "Id":<Id>,
```

```
      "Identities":[<List of Identities>]
}
```

Example Response

Status Code: 200

```
{
       "Id": <Id>,
       "Name": "<Name>",
       "Description": "<Description>",
       "Valid": true,
       "Permissions": "<List of Permissions>",
       "Identities": "List of Identities>"
}
```

3.3.7.7 Security DeleteRole

The POST DeleteRole endpoint can be used to delete a security role from Keyfactor Command. A role can be deleted by name or Id. The administrator role cannot be deleted.

Example Request

POST http://<host>/CMSApi/Security/1/DeleteRole

```
{
       "Id": <Id>
}
```

Example Response

Status Code: 200

```
{
       "Message": "Successfully deleted Role: <Name of Role>"
}
```

3.3.8 SSL

Keyfactor Command allows, through the Keyfactor Command Windows Agent, various network segments to be scanned for endpoints serving SSL certificates as well as endpoints presenting a certificate to be monitored for changes in status. An SSL scan is executed against an Endpoint Group, which is a collection of network endpoints, along with a scan schedule. Two types of endpoint groups exist:

- Discovery
  A Discovery endpoint group contains endpoints to be scanned for certificates.
- Monitoring
  A Monitoring group allows endpoints that presented a certificate in a discovery scan to be repeatedly scanned for changes.

The SSL Web API component allows SSL scan configuration to be retrieved and updated in order to facilitate rapid configuration of large numbers of network endpoints. The methods included in this component are given in Table 724: SSL Endpoints. As with the Certstore API component, the SSL component only has 1 version and all endpoints can be accessed through a URL path including */SSL/1/*.

Table 724: SSL Endpoints

Endpoint	Method	Description
AddEndpoint	POST	Add a new endpoint to an endpoint group
AddEndpointGroup	POST	Add a new endpoint group to an agent.
Agents	GET	Return a list of Agents that can perform SSL scans.
EndpointGroups	GET	Returns a list of established endpoint groups for a particular agent

3.3.8.1 SSL AddEndpoint

The AddEndpoing method allows an endpoint to be added to an endpoint group. It returns HTTP 200 OK with response body "true" for successful requests or an appropriate 4xx error with a message on a failure.

Table 725: POST /AddEndpoint Request Body

Parameter Name	Parameter Value
EndpointGroupId	GUID of the endpoint group to which the endpoint should be added, which can be obtained through a combination of the GET SSL/1/Agents and GET SSL/1/EndpointGroups methods.
ItemType	Format in which the network endpoint is defined. Possible values are:

<table>
<tr><th>Parameter Name</th><th>Parameter Value</th></tr>
<tr><td></td><td>
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>1</td><td>IPAddress</td></tr>
<tr><td>2</td><td>DnsName</td></tr>
<tr><td>3</td><td>NetworkNotation</td></tr>
</table>
</td></tr>
<tr><td>Value</td><td>String representing the endpoint. Should be formatted to match the expected format of the ItemType, e.g. "192.168.41.171:443" for IPAddress, "www.example.com:443" for DnsName, or "192.168.0.0/16:443" for NetworkNotation (corresponding to the IP address range 192.168.0.1-192.168.255.254, on port 443 for all endpoints).</td></tr>
</table>

Example Request

POST http://<host>/CMSApi/SSL/1/AddEndpoint HTTP/1.1

```
{
       "EndpointGroupId": <GUID>,
       "ItemType": 3,
       "Value": "192.168.0.0/24:443"
}
```

3.3.8.2 SSL AddEndpointGroup

The AddEndpoint Group method allows a new endpoint group to be added for an agent. This requires the two fields shown in Table 726: POST /AddEndpointGroup Request Body. When successful, the GUID and Name of the created endpoint group are returned.

Table 726: POST /AddEndpointGroup Request Body

Parameter Name	Parameter Value
AgentId	GUID of the Agent that will scan endpoints in this group.
FriendlyName	Name of the group to be created.

Table 727: POST /AddEndpointGroup Response Body

Parameter Name	Parameter Value
Guid	Identifier for this endpoint group within Keyfactor Command.
Name	Name of the endpoint group used by Keyfactor Command.

Example Request

POST http://<host>/CMSApi/SSL/1/AddEndpointGroup HTTP/1.1

```
{
       "AgentId": <GUID>,
       "FriendlyName": "local-endpoints"
}
```

Example Response

```
{
       "Guid": "0a44f8af-6808-40ad-9816-d08c2c45d45a",
       "Name": "local-endpoints"
}
```

3.3.8.3 SSL Agents

The Agents HTTP Get method takes no parameters and returns a list of agents that can perform SSL scans. The result will be an array of structures, each with a GUID and name.

Table 728: GET /Agents Response Body

Parameter Name	Parameter Value
Guid	Identifier for this agent within Keyfactor Command.
Name	Hostname of the agent used by Keyfactor Command.

Example Request

GET http://<host>/CMSApi/SSL/1/Agents

Example Response

```
[
	{
		"Guid": "956282ef-f01b-4ae3-8cd2-57327749e15c",
		"Name": "Dev1.jdk.com"
	}
]
```

3.3.8.4 SSL EndpointGroups

The EndpointGroups method returns the list of endpoint groups that have been defined for a particular agent. Unlike most methods in the Keyfactor Web APIs, this is a GET request that takes a parameter as part of the URL query string. The "agentId" required argument is the GUID of the agent for the endpoint groups that should be listed. This value can be retrieved from the GET /CMSApi/SSL/1/Agents response (see SSL Agents on the previous page). The response returned from this method will be an array of endpoint groups with the same structure as the response to AddEndpointGroup (see Table 727: POST /AddEndpointGroup Response Body).

Example Request

GET http://<host>/CMSApi/SSL/1/EndpointGroups?agentId=956282ef-f01b-4ae3-8cd2-57327749e15c HTTP/1.1

Example Response

```
[
	{
		"Guid": "bbf3c3ce-9d7f-48b1-ae5c-c8d38f41d2f1",
		"Name": "MyDiscoveryGroup"
	}
]
```

3.3.9 Workflow

Workflow in Keyfactor Command refers to the process through which pending certificate requests are approved or denied. The Workflow API provides the ability to obtain a list of pending certificate enrollment requests, and approve or deny current requests. This component, like several others, currently encompasses only one version, and methods can all be accessed with the */Workflow/1/* prefix. The methods within this component are listed in Table 729: Workflow Endpoints

Table 729: Workflow Endpoints

Endpoint	Method	Description
Approve	POST	Approve a given pending certificate request

Endpoint	Method	Description
Deny	POST	Deny a given pending certificate request
PendingList	POST	Retrieve a list of outstanding pending certificate requests
Status	GET	Synonym for GET CMSApi/Status (see Status on page 2196)

3.3.9.1 Workflow Approve and Deny

The Approve POST method will attempt to approve the provided pending certificate enrollment request(s), while POST Deny will attempt to deny the request(s). In both cases, the structure of the pending request(s) is the same—an array of pending certificate enrollment requests must be provided in the format given in Table 731: POST /Approve and /Deny PendingRequests Details. If only one request is to be sent, it should be provided as a list with one element. The one difference between the request formats for the two methods is that Deny supports an optional "Comments" field, which provides an opportunity to describe the reason for the request denial, shown in Table 730: POST /Approve and /Deny Request Body. In both cases, an array of successful, failed and forbidden requests will be returned. The method will accept various inputs used to qualify the request to be approved, as shown in Table 731: POST /Approve and /Deny PendingRequests Details.

Table 730: POST /Approve and /Deny Request Body

Parameter Name	Parameter Value
PendingRequests	Array of requests to be approved or denied. Required for both methods.
Comments	String describing the reason for the request denial. Optional for Deny and not permitted for Approve.

Table 731: POST /Approve and /Deny PendingRequests Details

Parameter Name	Parameter Value
CMSRequestId	The Keyfactor Command request database identifier. This parameter is the most specific, and can be used without any other parameters provided. An exception will be returned if this identifier is not found within Keyfactor Command.
CAHost	Host name of the certificate authority against which the certificate enrollment request was submitted. This parameter also requires the CALogicalName and CARequestId parameters to be provided in the request. An exception will be returned if a certificate authority with this host, logical name and request ID is not found within Keyfactor Command.
CALogicalName	Logical name of the certificate authority against which the certificate enrollment request was submitted. This parameter also requires the CAHost and CARequestId parameters to be provided in the request. An exception will be returned if a certificate authority with this host, logical name and

Parameter Name	Parameter Value
	request ID is not found within Keyfactor Command.
CARequestId	Request/row identifier of the request for certificate authority defined by CAHost and CALogicalName. This parameter also requires the CALogicalName and CAHost parameters to be provided in the request. An exception will be returned if a certificate authority with this host, logical name and request ID is not found within Keyfactor Command.

Table 732: POST /Approve and /Deny Response Body

Parameter Name	Parameter Value
Successes	An array of the successful approval response details (see table below in this section).
Failures	An array of the failed approval response details (see table below in this section). Failures of this type are generally exceptions.
Denials	An array of the approval requests that were denied (see table below in this section). Denials are usually created by insufficient user permissions required to perform the approval.

Table 733: POST /Approve and /Deny Result Details

Parameter Name	Parameter Value
CAHost	Host name of the certificate authority against which the certificate enrollment request was submitted.
CALogicalName	Logical name of the certificate authority against which the certificate enrollment request was submitted.
CMSRequestId	The Keyfactor Command request database identifier.
CARequestId	Request/row identifier of the request for certificate authority defined by CAHost and CALogicalName.
Comment	Brief description of the reason for the failure or denial, or simply ‘Success’ if the request succeeded.

Example Request

Providing only a CMSRequestId

POST http://<host>/CMSApi/Workflow/1/Approve HTTP/1.1

```
{
       "PendingRequests":
       [
       {"CMSRequestId": <cms-request-id1>},
       {"CMSRequestId": <cms-request-id2>}
       ]
}
```

Example Request

Providing the certificate authority information

POST http://<host>/CMSApi/Workflow/1/Approve HTTP/1.1

```
{
       "PendingRequests":
       [{
       "CAHost":"<ca-host>","CALogicalName":"<ca-name>","CARequestId":<ca-request-id>
       }]
}
```

Example Request

Providing both types of information

POST http://<host>/CMSApi/Workflow/1/Approve HTTP/1.1

```
{
       "PendingRequests":
       [
       {"CMSRequestId":<cms-request-id1>},
       {"CAHost":"<ca-host>","CALogicalName":"<ca-name>","CARequestId":<ca-request-id>}
       ]
}
```

Example Response

(Successful)

```
{
       "Successes":
       [{
```

```
        "CAHost": "<ca-host>",
        "CALogicalName": "<ca-name>",
        "CARequestId": <ca-request-id>,
        "Comment": "Successful"
        }],
        "Failures": [],
        "Denials": []
}
```

Example Response

(Invalid identifier)

```
{
        "Successes": [],
        "Failures": [{
        "CAHost": "<ca-host>",
        "CALogicalName": "<ca-name>",
        "CARequestId": <ca-request-id>,
        "CMSRequestId": <cms-request-id>,
        "Comment": "Unable to approve the request: <ca request id> for the certificate authority: '<ca-host-
name>\<ca-logical-name>' \r\nfor the current user: '<requester>': No request for: CMS Request Id: 0,
CA Host: <ca-host>, CA Logical Name: <ca-name>, CA Request Id: <ca-request-id>"
        }],
        "Denials": []
}
```

3.3.9.2 PendingList

The POST PendingList method will return the current set of pending certificate enrollment requests stored within Keyfactor Command matching the provided parameters. The response will be a JSON object with a single field , PendingRequests, mapped to an array where each entry represents a single pending certificate request that matches the parameters provided in the HTTP request. Each of these entries will have the format given in Table 735: POST /PendingList Response Body.

Table 734: POST /PendingList Request Body

Parameter Name	Parameter Value
CAHost	Host name of the certificate authority against which the certificate enrollment request was submitted. This parameter also requires the CALogicalName parameter to be provided in the request. An exception will be returned if a certificate authority with this host and logical name is not found within Keyfactor Command.

Parameter Name	Parameter Value
CALogicalName	Logical name of the certificate authority against which the certificate enrollment request was submitted. This parameter also requires the CAHost parameter to be provided in the request. An exception will be returned if a certificate authority with this host and logical name is not found within Keyfactor Command.
LowerDate	Any pending requests prior to this date should be ignored. Optional.
UpperDate	Any pending requests after this date should be ignored. Optional.

Table 735: POST /PendingList Response Body

Parameter Name	Parameter Value
CAHost	Host name of the certificate authority against which the certificate enrollment request was submitted.
CALogicalName	Logical name of the certificate authority against which the certificate enrollment request was submitted.
CARequestId	Identifier associated with the request within the certificate authority.
CertificateAuthority	Combination of the CAHost and CALogicalName (CAHost\\CALogicalName).
CMSRequestId	Database identifier associated with the request within Keyfactor Command.
CommonName	Common name requested for the certificate.
DistinguishedName	Distinguished name requested for the certificate.
TemplateName	Certificate template for which the certificate was requested.
KeySize	Number of bits in the certificate's private key.
Requester	User or principal who requested the certificate, generally formatted "DOMAIN\\user".
SubmissionDate	ISO-8601 formatted timestamp at which the certificate request was received.
SubjectAlternativeName	Array of SANs requested for the certificate. The entries each correspond to one requested SAN element, and each one will be in the form given in Table 736: POST /PendingList SubjectAlternativeName Details

Table 736: POST /PendingList SubjectAlternativeName Details

<table>
<tr><th>Parameter Name</th><th>Parameter Value</th></tr>
<tr><td>Type</td><td>Type of this SAN element on the certificate request. Will take one of the following values:
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>0</td><td>Other</td></tr>
<tr><td>1</td><td>RFC 822 name (e-mail address)</td></tr>
<tr><td>2</td><td>DNS name</td></tr>
<tr><td>3</td><td>X400 address</td></tr>
<tr><td>4</td><td>Directory Name</td></tr>
<tr><td>5</td><td>Edi Party Name</td></tr>
<tr><td>6</td><td>URI</td></tr>
<tr><td>7</td><td>IP address</td></tr>
<tr><td>8</td><td>Registered ID</td></tr>
<tr><td>100</td><td>Microsoft NT Principal Name</td></tr>
<tr><td>101</td><td>Microsoft NTDS Replication</td></tr>
<tr><td>999</td><td>Unknown</td></tr>
</table></td></tr>
<tr><td>Value</td><td>String representation of the value requested for this SAN element.</td></tr>
</table>

Example Request

POST http://<host>/CMSApi/Workflow/1/PendingList HTTP/1.1

```
{
       "CAHost": "<ca-host>",
       "CALogicalName": "<ca-name>",
       "LowerDate": <date or null or left out completely>,
       "UpperDate": <date or null or left out completely>
}
```

Example Response

```
{
        "PendingRequests":
        [{
        "CAHost":"<ca-host>",
        "CALogicalName":"<ca-name>",
        "CARequestId":<ca-request-id>,
        "CMSRequestId":<cms-request-id>
        }]
}
```

3.3.10 Workflow Expiration Alerts

Workflow in Keyfactor Command refers to the process through which pending certificate requests are approved or denied. The Workflow Expiration Alert APIs provides the ability to manage expiration alerts, event handlers, registered event handlers and schedules.

3.3.10.1 Workflow Expiration Alerts Endpoints

The Workflow Expiration Alert API provides the ability to list, create, update and delete expiration alerts for Keyfactor Command via the Keyfactor API. The methods within this component are listed in Table 737: Workflow Expiration Alerts Endpoints

Table 737: Workflow Expiration Alerts Endpoints

Endpoint	Method	Description
ExpirationAlerts	GET	List all Expiration Alerts or a get a single expiration alert definition.
ExpirationAlerts	POST	Create a new expiration alert definition.
ExpirationAlerts	PUT	Update an existing expiration alert definition.
ExpirationAlerts	DELETE	Delete an existing expiration alert definition.

Workflow Expiration Alerts

Note: For the GET (single), PUT, and DELETE methods you will need the expiration alert ID. You will need to run the GET (list) method to acquire the ID in order to proceed with those methods.

Note: For the POST and PUT methods, if you are using Registered Event Handlers, you will need to run the Event handler GET (list) method to acquire the ID prior to issuing the expiration alert method (see Workflow Expiration Alert Handler Parameters Endpoints on page 2191).

Table 738: Workflow Expiration Alert Parameters

Parameter Name	Parameter Value
Id/Alert ID	The database ID of the Alert
DisplayName	Alert display name
Subject	The subject field of the alert
Message	The message field of the alert
UseHandler	True/False, whether or not the Use Handler checkbox is checked for the alert
Days	The number of days to alert before expiration
RegisteredEventHandlerId	Id of the Event Handler to use. See (Workflow Expiration Alert Handler Parameters Endpoints on page 2191)
CertificateQuery	Name, and/or Id, of the certificate collection of the alert
ExpirationAlertRecipients	Id and/or Recipient email address in a comma separated list of objects. So there could be multiple addresses chunks in curly brackets{}, comma separated in the array in the square brackets []

LIST all expiration alerts:

Example Request

GET ~/ExpirationAlerts/1/List?page=<page number>&returnlimit=<max results to get>&sortname=<field to sort by>&sortorder=<asc or desc>

```
no body
```

Example Response

```
[
  {
    "Id": <id>,
    "DisplayName": "Alert display name",
    "QueryName": "Certificate query name",
    "Days": <number of days to alert before expiration>,
    "HandlerName":  "Name of the Event Handler if any"
```

```
  }
]
```

Get a single alert definition

Example Request

GET ~/ExpirationAlerts/1/<Alert Id>

```
no body
```

Example Response

```
[
  {
    "Id": <id>,
    "DisplayName": "Alert display name",
    "Subject": "Alert Subject",
    "Message": "Alert message body",
    "UseHandler":  <true/false>,
    "Days": <number of days to alert before expiration>,
    "RegisteredEventHandlerId":  <Id of the Event Handler to use>,
    "CertificateQuery": { "Id": <Cert query id>, "Name": "Cert query name" },
    "ExpirationAlertRecipients": [ { "Id": <recipient Id>, "Email": "Recipient email address" } ]
  }
]
```

Create New Expiration Alert

Example Request

POST ~/ExpirationAlerts/1/

```
 {
    "DisplayName": "Alert display name",
    "Subject": "Alert Subject",
```

```
  "Message": "Alert message body",
  "UseHandler":  <true/false>,
  "Days": <number of days to alert before expiration>,
  "RegisteredEventHandlerId":  <Id of the Event Handler to use>,
  "CertificateQuery": { "Id": <Cert query id> },
  "ExpirationAlertRecipients": [ { "Email": "Recipient email address" } ]
}
```

Example Response

```
{
  "Id": <id>,
  "DisplayName": "Alert display name",
  "Subject": "Alert Subject",
  "Message": "Alert message body",
  "UseHandler":  <true/false>,
  "Days": <number of days to alert before expiration>,
  "RegisteredEventHandlerId":  <Id of the Event Handler to use>,
  "CertificateQuery": { "Id": <Cert query id>, "Name": "Cert query name" },
  "ExpirationAlertRecipients": [ { "Id": <recipient Id>, "Email": "Recipient email address" } ]
}
```

Update Existing Expiration Alert

Example Request

PUT ~/ExpirationAlerts/1/<Alert Id>

```
{
   "DisplayName": "Alert display name",
   "Subject": "Alert Subject",
   "Message": "Alert message body",
   "UseHandler":  <true/false>,
   "Days": <number of days to alert before expiration>,
   "RegisteredEventHandlerId":  <Id of the Event Handler to use>,
   "CertificateQuery": { "Id": <Cert query id> },
   "ExpirationAlertRecipients": [ { "Email": "Recipient email address" } ]
 }
```

Example Response

```
{
  "Id": <id>,
  "DisplayName": "Alert display name",
  "Subject": "Alert Subject",
  "Message": "Alert message body",
  "UseHandler":  <true/false>,
  "Days": <number of days to alert before expiration>,
  "RegisteredEventHandlerId":  <Id of the Event Handler to use>,
  "CertificateQuery": { "Id": <Cert query id>, "Name": "Cert query name" },
  "ExpirationAlertRecipients": [ { "Id": <recipient Id>, "Email": "Recipient email address" } ]
}
```

Delete Expiration Alert

Example Request

DELETE ~/ExpirationAlerts/1/<Alert Id>

```
no body
```

Example Response

204 No Content

3.3.10.2 Workflow Expiration Alert Event Handler Parameters API

The Workflow Expiration Alert Event Handler Parameter API provides the ability to list, create, update and delete expiration alert event handler parameters for specific Keyfactor Command expiration alerts via the Keyfactor API. The methods within this component are listed in Table 739: Workflow Expiration Alerts Event Handler Parameters Endpoints

Table 739: Workflow Expiration Alerts Event Handler Parameters Endpoints

Endpoint	Method	Description
HandlerParameters	GET	List all, or a given, expiration alert Handler Parameter(s) for an expiration alert.
HandlerParameters	POST	Create a new handler parameter for an expiration alert.
HandlerParameters	PUT	Update an existing expiration alert handler parameter for an expiration alert.
HandlerParameters	DELETE	Delete an existing expiration alert handler parameter for an expiration alert.

Workflow Expiration Alert Handler Parameters Endpoints

Note: For the GET (single), PUT, and DELETE methods you will need the handler parameter ID. You will need to run the GET (list) method to acquire the ID in order to proceed with those methods.

Table 740: Workflow Expiration Alert Handler Parameters

Parameter Name	Parameter Value
Id/Alert ID	The database ID of the handler parameter
Key	The parameter name
DefaultValue	The given value for the handler parameter
ParameterType	The event handler parameter type number Special Text: 0 Static Value: 1 PowerShell Script Name: 2 Logging Target Machine: 3 Renewal URL: 4 Renewal Template: 5 Renewal Certificate Authority: 6
ExpirationAlertDefinitionId	The database ID of the expiration alert definition

List All Handler Parameters for an Expiration Alert:

Example Request

GET ~/ExpirationAlerts/1/<Alert Id>/HandlerParameters/List?page=<page number>&returnlimit=<max results to get>&sortname=<field to sort by>&sortorder=<asc or desc>

```
no  body
```

Example Response

```
[
  {
    "Id": <id>,
    "Key": "Parameter Key name",
    "DefaultValue": "default value for parameter",
    "ParameterType": <Event Handler Parameter Type number>,
    "ExpirationAlertDefinitionId":  <alert Id>
  }
]
```

Get Handler Parameter by Id

Example Request

GET ~/ExpirationAlerts/1/<Alert Id>/HandlerParameters/<handler param Id>

```
no body
```

Example Response

```
[
  {
    "Id": <id>,
    "Key": "Parameter Key name",
    "DefaultValue": "default value for parameter",
    "ParameterType": <Event Handler Parameter Type number>,
    "ExpirationAlertDefinitionId":  <alert Id>
  }
]
```

Create New Handler Parameter

Example Request

POST ~/ExpirationAlerts/1/<Alert Id>/HandlerParameters

```
  {
    "Key": "Parameter Key name",
    "DefaultValue": "default value for parameter",
    "ParameterType": <Event Handler Parameter Type number>,
   }
```

Example Response

```
{
    "Id": <id>,
    "Key": "Parameter Key name",
    "DefaultValue": "default value for parameter",
    "ParameterType": <Event Handler Parameter Type number>,
   }
```

Update Existing Handler Parameter

Example Request

PUT ~/ExpirationAlerts/1/<Alert Id>/HandlerParameters/<handler param Id>

```
  {
    "Key": "Parameter Key name",
    "DefaultValue": "default value for parameter",
    "ParameterType": <Event Handler Parameter Type number>,
   }
```

Example Response

```
{
    "Id": <id>,
    "Key": "Parameter Key name",
    "DefaultValue": "default value for parameter",
    "ParameterType": <Event Handler Parameter Type number>,
   }
```

Delete Handler Parameter

Example Request

DELETE ~/ExpirationAlerts/1/<Alert Id>/HandlerParameters/<handler param Id>

```
no  body
```

Example Response

204 No Content

3.3.10.3 Workflow Expiration Alert Registered Event Handlers API

The Workflow Expiration Alert Registered Event Handlers API provides the ability to list expiration alert registered event handlers: for Keyfactor Command via the Keyfactor API. The methods within this component are listed in Table 741: Workflow Expiration Alerts Registered Event Handlers Endpoints

Table 741: Workflow Expiration Alerts Registered Event Handlers Endpoints

Endpoint	Method	Description
RegisteredEventHandlers	GET	Get list of Registered Event Handlers

Workflow Expiration Alert Registered Event Handlers Parameters

Table 742: Workflow Expiration Alert Registered Event Handlers Parameters

Parameter Name	Parameter Value
Id	The database ID of the registered event handler
Classname	Fully qualified class name of the registered event handler implementation in the associated assembly
DisplayName	The display name of registered event handler
Enabled	True/False, whether or not the Use Handler checkbox is checked for the alert
RegisteredEventAssemblyId	The Id of the registered event handler assembly

LIST all Registered Event Handlers:

Example Request

GET ~/ExpirationAlerts/1/RegisteredEventHandlers/List?page=<page number>&returnlimit=<max results to get>

```
no body
```

Example Response

```
{
  "Id": <registered event handler Id>,
  "ClassName": "class name of event handler",
  "DisplayName": "display name of event handler",
  "Enabled": <true/false>,
  "RegisteredEventAssemblyId":  <id of the registered event assembly>
}
```

3.3.10.4 Workflow Expiration Alert Schedule API

The Workflow Expiration Alert Schedule API provides the ability to list, create, and set expiration alert schedules for Keyfactor Command via the Keyfactor API. The methods within this component are listed in Table 743: Workflow Expiration Alerts Schedule Endpoints

Table 743: Workflow Expiration Alerts Schedule Endpoints

Endpoint	Method	Description
Schedule	GET	Get the schedule set for all expiration alerts.
Schedule	POST	Create a new schedule for an expiration alert.

Workflow Expiration Alert Schedule Parameters

Table 744: Workflow Expiration Alert Schedule Parameters

Parameter Name	Parameter Value
Daily	The display name of registered event handler
Time	The ISO string of time to schedule run

LIST Expiration Alert Schedule

Example Request

GET ~/ExpirationAlerts/1/Schedule

```
no body
```

Example Response

```
{
  "Daily": {
    "Time":"ISO string of time to schedule run"
   }
}
```

Set Alerts Schedule

Example Request

POST ~/ExpirationAlerts/1/Schedule

```
{
  "Daily": {
    "Time":"ISO string of time to schedule run"
   }
}
```

Example Response

204 No Content

3.3.11 Status

The Status Web API component provides a single method to retrieve various aspects of the Keyfactor Command server state. This method is an HTTP GET Status request with no parameters required. As of Keyfactor Command 5.0, the Status endpoint generally is not needed by a Web API client application, as the Keyfactor Command version is passed back in an HTTP header with every response to every Web API request. However, it is included to preserve compatibility with applications already using it or applications requiring more information.

Example Request

GET http://<host>/CMSApi/Status HTTP/1.1

Example Response

Status Code: 200

```
{
	"ApiMajorRev": 2,
	"ApiMinorRev": 0,
	"ProductMajorVersion": 5,
	"ProductMinorVersion": 0,
	"ProductBranchVersion": 0,
	"ProductBuildVersion": 1,
	"LicenseStatus": "Licensed",
	"Modules": [{
		"Name": "CertEnroll",
		"Versions": [1, 2, 3]
	},
	{
		"Name": "Certificates",
		"Versions": [1, 2, 3]
	},
	{
		"Name": "CertStore",
		"Versions": [1]
	},
	{
		"Name": "Metadata",
		"Versions": [2, 3]
	},
	{
		"Name": "Ssl",
		"Versions": [1]
	},
	{
		"Name": "Status",
		"Versions": null
	},
	{
		"Name": "Workflow",
		"Versions": [1]
	}]
}
```

3.3.12 vSCEP

The vSCEP API method supports enrollment through the Keyfactor Command implementation of the SCEP protocol. The single method—GET CMSValidation/api/vSCEP—is used to retrieve a SCEP challenge, while also associating that challenge with the specified certificate subject information. This method differs from the other Web API methods in that it is not included in the CMSApi virtual directory, but in the separate "CMSValidation/api" directory. It also differs in that, while it is a GET method, it does take request parameters, which means that these parameters must be URL-encoded in the query string. Like the other Web API methods, however, it requires the Accept and Authorization headers, and returns a 200 OK status if a connection was successfully made to the vSCEP server or an appropriate 4XX status if a connection could not be made. The request and response formats are given in the below tables and example. All fields in the request are optional, and all but the Subject parameter may be submitted multiple times (for example, to include two different DNS SANs in the same certificate).

Table 745: GET /CMSValidation/api/vSCEP Query String Parameters

Parameter Name	Parameter Value
Subject	Distinguished Name that should be used as the certificate subject.
DNS	Subject Alternative Name representing a DNS record.
IP	Subject Alternative Name representing an IP address.
RFC822	Subject Alternative Name representing an RFC822 Name (email address).
NTPrincipal	Subject Alternative Name representing an NT Principal Name.

Table 746: GET /CMSValidation/api/vSCEP Response Body

Parameter Name	Parameter Value
Status Code	HTTP Status Code vSCEP received from the SCEP server. This will be 200 if the request was successful.
Message	Status message for the request. In the case of an error retrieving a SCEP challenge, this will provide more detailed error information.
Challenge	SCEP Challenge represented as a hex string. In the case of an error, this will be null.
Hash	MD5 hash of the CA certificate associated with the SCEP server. In the case of an error, this will be null.

Example Request

GET http://<host>/CMSValidation/api/vSCEP?subject=CN%3DBob%20Smith%2CO%3DExample%20Company&RFC822=bob.smith%40mail.example.com HTTP/1.1

Example Response

Status Code: 200

```
{
        "Challenge":"247FAFEEABA1F9B7",
        "Hash":"01940B86 9C6C03DC 79BF2E5B 741779DF",
        "StatusCode":200,
        "Message":"Request stored successfully"
}
```

3.4 API Change Log

In this section you will find the change history for the Keyfactor Command API endpoints from version 9.0 on.

/SSH/Keys/Unmanaged	DELETE	Add	
/SSH/ServiceAccounts	DELETE	Add	
/SSH/Users/Access	POST	Add	
/SSL/Networks/{id}/Scan	POST	Add	

3.4.1.2 API Change Log v9.1

API changes for Keyfactor Command version 9.1 incremental release

Table 748: API Change Log v9.1

Endpoint	Methods	Action	Notes
/CertificateStores/{id}/Inventory	GET	Add	
/Enrollment/PFX/Replace	POST	Fix	SuccessfulStores collection now only includes Ids of stores that were successfully processed.
/Enrollment/PFX/Deploy	POST	Update	Now allows for multiple stores of the same type with different parameters.
/CertStoreTypes	POST/PUT	Update	EntryParameters can now be set via these methods.
/CertificateStores/Certificates/Add	POST	Update	Now allows for multiple stores of the same type with different parameters.
/CertificateStores/Certificates/Remove	POST	Update	Now allows for multiple stores of the same type with different parameters.
/CertificateCollections/{id}/Permissions	GET	Deprecate	

3.4.1.3 API Change Log v9.2

API changes for Keyfactor Command version 9.2 incremental release

Table 749: API Change Log v9.2

Endpoint	Methods	Action	Notes
/Certificates	GET	Fix	No longer fails if a collection id is not provided.
/OrchestratorJobs/JobHistory	GET	Fix	Request no longer fails for 'Dynamic' job types.
/Reports/Schedules/{id}	DELETE	Fix	Response code is now 200 when the user role does not have *Modify – Report* permission.

3.4.1.4 API Change Log v9.3

API changes for Keyfactor Command version 9.3 incremental release

Table 750: API Change Log v9.3

Endpoint	Methods	Action	Notes
/JobTypes/Custom	POST	Fix	No longer requires default field values.

3.4.1.5 API Change Log v9.4

API changes for Keyfactor Command version 9.4 incremental release

Table 751: API Change Log v9.4

Endpoint	Methods	Action	Notes
/Workflow/Certificates/Pending	GET	Update	Now returns the associated metadata.

3.4.1.6 API Change Log v9.5

API changes for Keyfactor Command version 9.5 incremental release

Table 752: API Change Log v9.5

Endpoint	Methods	Action	Notes
/Enrollment/PFX	POST	Update	No longer requires a certificate authority name to be provided.

3.4.1.7 API Change Log v9.6

API changes for Keyfactor Command version 9.6 incremental release.

No API endpoint changes were made in this release.

3.4.1.8 API Change Log v9.7

API changes for Keyfactor Command version 9.7 incremental release

Table 753: API Change Log v9.7

Endpoint	Methods	Action	Notes
/KeyfactorAPI/License	GET	Add	

3.4.1.9 API Change Log v9.8

API changes for Keyfactor Command version 9.8 incremental release.

No API endpoint changes were made in this release.

3.4.1.10 API Change Log v9.9

API changes for Keyfactor Command version 9.9 incremental release

Table 754: API Change Log v9.9

Endpoint	Methods	Action	Notes
/Reports/<any>	GET	Fix	Spaces within the sortField no longer results in an exception.
/Reports/{id}/Schedules	GET	Fix	An invalid sortField no longer results in an exception.
/Agents	GET	Update	New query parser to support the AgentId GUID.

3.4.2 v10 API Change Log

Find the version 10 change log for Keyfactor API below.

Link to Change Logs
API Change Log v10.0 below

3.4.2.1 API Change Log v10.0

API changes for Keyfactor Command version 10.0 Major release

Table 755: API Change Log v10.0

Endpoint	Methods	Action	Notes
/Agents/{id}	GET	Add	
/Agents/Reset	POST	Add	
/AgentBlueprint	GET	Add	
/AgentBlueprint/{id}	GET, DELETE	Add	
/AgentBlueprint/{id}/Jobs	GET	Add	
/AgentBlueprint/{id}/Stores	GET	Add	
/AgentBluePrint/ApplyBlueprint	POST	Add	
/AgentBluePrint/GenerateBluePrint	POST	Add	
/Alerts/Denied	GET, PUT, POST	Add	
/Alerts/Denied/{id}	GET, DELETE	Add	
/Alerts/Expiration	GET, PUT, POST	Add	
/Alerts/Expiration/{id}	GET, DELETE	Add	
/Alerts/Expiration/Schedule	GET, PUT	Add	
/Alerts/Expiration/Test	POST	Add	
/Alerts/Expiration/TestAll	POST	Add	
/Alerts/IssuedAlerts	GET, PUT, POST	Add	
/Alerts/IssuedAlerts/{id}	GET, DELETE	Add	
/Alerts/Issued/Schedule	GET, PUT	Add	
/Alerts/KeyRotation	GET, PUT, POST	Add	
/Alerts/KeyRotation/{id}	GET, DELETE	Add	
/Alerts/KeyRotation/Schedule	GET, PUT	Add	

Endpoint	Methods	Action	Notes
/Alerts/KeyRotation/Test	POST	Add	
/Alerts/KeyRotation/TestAll	POST	Add	
/Alerts/Pending	GET, PUT, POST	Add	
/Alerts/Pending/{id}	GET, DELETE	Add	
/Alerts/Pending/Schedule	GET, PUT	Add	
/Alerts/Pending/Test	POST	Add	
/Alerts/Pending/Test/{id}	POST	Add	
/CertificateAuthorities	GET	Update	Schedules are now included in the results.
/CertificateAuthorities	POST	Update	Ability to turn off schedules, sessions are abandoned properly, and threshold monitoring schedule is included.
/CertificateAuthorities/{id}	PUT	Update	Ability to turn off schedules, sessions are abandoned properly, and threshold monitoring schedule is included.
/CertificateAuthorities/{id}	DELETE	Update	Deletion is now prevented if schedules are associated.
/CertificateCollections	POST	Update	Query parameter no longer needed when a valid CopyFromId is provided.
/CertificateCollections/{id}/Permissions	POST	Deprecated	Replaced by /Security/Roles/{id}/Permissions/Collection.
/Certificates/Analyze	POST	Add	
/Certificates/IdentityAudit/{id}	GET	Add	
/CertificateStoreContainers	POST	Add	
/CertificateStoreContainers/{id}	PUT, DELETE	Add	
/CertificateStores/Server	GET, POST, PUT	To Be Deprecated	Server usernames, server passwords, and the UseSSL flag are managed by

Endpoint	Methods	Action	Notes
			the /CertificateStores API endpoints directly as JobProperties using the Properties parameter, replacing the deprecated /CertificateStores/Server API endpoints.
/CertificateStores	GET, POST, PUT	Updated	Server usernames, server passwords, and the UseSSL flag are managed by the /CertificateStores API endpoints directly as JobProperties using the Properties parameter, replacing the deprecated /CertificateStores/Server API endpoints.
/Enrollment/PFX (v2)	POST	Add	
/Enrollment/Settings/{id}	GET	Add	
/JobTypes/Custom	POST	Update	DefaultValue property is no longer required, validation is now performed on the JobTypeFields/DefaultValue property, validation prevents names containing spaces.
/JobTypes/Custom/{id}	DELETE	Update	Includes validation so that deletion is prevented if at least one associated approved orchestrator implements the capability.
/MacEnrollment	GET, PUT	Add	
/Monitoring/Revocation	GET, POST	Update	Renamed from /Workflow/RevocationMonitoring
/Monitoring/Revocation/{id}	GET, PUT, DELETE	Update	Renamed from /Workflow/RevocationMonitoring/{id}
/Monitoring/Revocation/Test	POST	Add	
/Monitoring/Revocation/TestAll	POST	Add	
/Orchestrators/JobHistory	GET	Update	Added JobId field.
/Orchestrators/ScheduledJobs	GET	Add	
/OrchestratorJobs/Reschedule	POST	Add	

Endpoint	Methods	Action	Notes
/OrchestratorJobs/Unschedule	POST	Add	
/OrchestratorJobs/Acknowledge	POST	Add	
/Security/Identities/{id}	GET	Add	
/Security/Roles/{id}/Identities	GET, POST	Add	
/Security/Roles/{id}/Containers	GET, POST	Add	
/Security/Roles/{id}/Copy	POST	Add	
/Security/Roles/{id}/Permissions	GET	Add	
/Security/Roles/{id}/Permissions/Global	GET, POST, PUT	Add	
/Security/Roles/{id}/Permissions/Collections	GET, POST, PUT	Add	Replaced the /CertificateCollections/{id}/Permissions endpoint functionality.
/Security/Roles/{id}/Permissions/Containers	GET, POST, PUT	Add	Returns only containers that have a permission set for the selected security role.
/SMTP	GET, PUT	Add	
/SMTP/Test	POST	Add	
/Templates	GET, PUT	Update	Includes template-specific policy information.
/Templates/{id}	GET	Update	Includes template defaults.
/Templates/Settings	GET, PUT	Update	Includes global template policies.
/Template/SubjectParts	GET	Add	
/Templates/Global/Settings	GET, PUT	Add	
/Templates/Import	POST	Add	
/Workflow/Certificates/Pending	GET	Update	Now supports query fields of Requester and RequestType.
/Workflow/Definitions/Steps/{extensionName}	GET	Add	

Endpoint	Methods	Action	Notes
/Workflow/Definitions/{definitionId}	GET, PUT, DELETE	Add	
/Workflow/Definitions	GET, POST	Add	
/Workflow/Definitions/Steps	GET	Add	
/Workflow/Definitions/Types	GET	Add	
/Workflow/Definitions/{definitionId}/Steps	PUT	Add	
/Workflow/Definitions/{definitionId}/Publish	POST	Add	
/Workflow/Instances/{instanceId}	GET, DELETE	Add	
/Workflow/Instances	GET	Add	
/Workflow/Instances/My	GET	Add	
/Workflow/Instances/AssignedToMe	GET	Add	
/Workflow/Instances/{instanceId}/Stop	POST	Add	
/Workflow/Instances/{instanceId}/Signals	POST	Add	
/Workflow/Instances/{instanceId}/Restart	POST	Add	

3.4.2.2 API Change Log v10.1

API changes for Keyfactor Command version 10.1 incremental release

Table 756: API Change Log v10.1

Endpoint	Methods	Action	Notes
/Templates	PUT, GET	Update	Ed448 and Ed25519 keys are now supported for certificate enrollment, policy, import and search.
/Templates/{id}	GET	Update	Ed448 and Ed25519 keys are now supported for certificate enrollment, policy, import and search.
/Templates/Settings	PUT, GET	Update	Ed448 and Ed25519 keys are now supported for certificate enrollment, policy, import and search.

3.4.2.3 API Change Log v10.2

API changes for Keyfactor Command version 10.2 incremental release

Table 757: API Change Log v10.2

Endpoint	Methods	Action	Notes
/Security/My	GET	Add	Returns all the security roles and global permissions for the requesting user.
/Enrollment/CSR	POST	Update	The workflow instance ID has been added to the response.
/Enrollment/CSR	POST	Update	A new PrivateKey input field has been added to support private key retention on CSR enrollment.
/Enrollment/PFX	POST	Update	The workflow instance ID has been added to the response.
/Certificates/Analyze	POST	Update	The endpoint requires Global Certificates-Read or Certificates-Import permissions.

4.0 Installing Servers

The Keyfactor Command solution by Keyfactor allows you to issue and manage certificates across enterprise infrastructures to allow you to achieve end-to-end visibility, control, and automation across all your machine identities so you can turn the impossible into the possible. It includes a web-based Management Portal running on a SQL backend providing the command and control center for managing certificates in the enterprise.

Keyfactor Command provides:

- Visibility

  Identify risks and prevent outages more effectively with a complete and continuous inventory of all your cryptographic assets.

- Control

  Have ultimate flexibility to make all certificates trusted, compliant, and up-to-date—and keep them that way.

- Automation

  Replace manual, error-prone tasks with automated key and certificate discovery, management, and renewal.

- Orchestration

  Move from DevOps to DevSecOps by orchestrating and expanding cryptography to secure software delivery pipelines.

In addition to the Management Portal, Keyfactor also offers:

- Several agents and orchestrators for managing certificates in certificates stores via the Management Portal (see Installing Orchestrators on page 2355 in the *Keyfactor Orchestrators Installation and Configuration Guide*).
- Several certificate authority gateways to support management of and enrollment for certificates from remote and cloud-based certificate providers via the Management Portal.
- APIs that integrate with the product to provide for customization (see Web APIs Reference on page 717 in the *Keyfactor Web APIs Reference Guide*).
- A certificate authority policy module with several policy handlers to provide policy control at the Microsoft CA level (see Keyfactor CA Policy Module on page 2318).
- An SSH Key Manager that extends beyond certificate management and traditional PKI to give security and network teams a simple, centralized solution to discover and manage SSH keys across their server and cloud infrastructure (see SSH on page 479 in the *Keyfactor Command Reference Guide*).

Uniquely designed for PKI administrators to operate an enterprise PKI, it's never been easier to issue, revoke, renew, or replace a digital certificate. With exceptionally robust reporting and management capabilities for all the certificates in an IT environment, the PKI administrator has a truly scalable and entirely secure system for operating an enterprise PKI.

4.1 Logical Architecture

Keyfactor Command is an n-tier application, consisting of a web/presentation layer, application tier, and database tier. In addition, Keyfactor Command optionally includes a number of enrollment and management components to help facilitate secure and/or automated certificate issuance and delivery to various server, client, and mobile platforms. The following sections provide views of the Keyfactor Command architecture from a logical and physical standpoint.

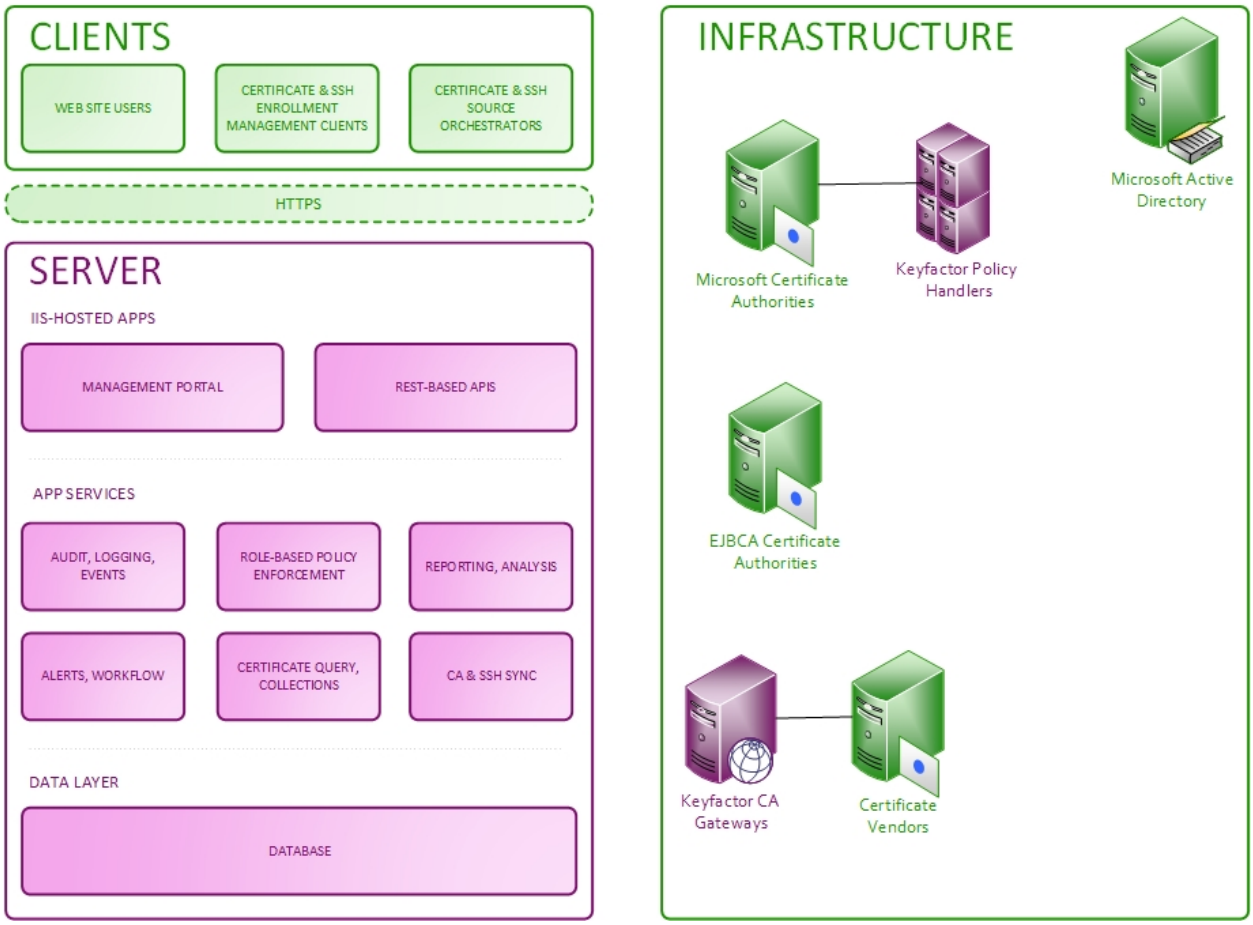

Figure 432: Keyfactor Command Logical Architecture Diagram

The Keyfactor Command solution includes the following logical components:

- Client / Orchestrator Tier:
  - Certificate Enrollment and Management Tools—While many certificate management functions can be performed in a completely agentless fashion, Keyfactor Command provides a number of enrollment and management tools to enable enhanced functionality where needed.
  - Certificate Source Orchestrators (aka Agents) and Gateways—Keyfactor Command gathers information about an enterprise's certificates and SSH keys from a number of different sources, including Microsoft and EJBCA CA databases, SSL scans, SSH key scans, API-based import, Java keystores, PEM certificate

stores, F5 devices, NetScaler devices, Amazon Web Services (AWS) locations, select certificate vendor certificates via gateways, and manual import through the Keyfactor Command Management Portal.

- Web Tier:
  - Management Portal—Keyfactor Command includes a web-based Management Portal that provides a PKI operations dashboard for administrators. It also enables certificate officers to easily search for and locate certificates and then perform management functions on them such as revocation or recovery. In addition, Keyfactor Command allows every certificate to be tagged with additional customer-defined metadata about the certificate, such as points of contact, certificate/app owners, etc. From within the Management Portal, administrators can inventory and manage secure shell (SSH) keys across the enterprise, while users can issue new SSH keys.
  - Enrollment Web Pages—Keyfactor Command includes issuance capabilities to a wide array of platforms, including Mac auto-enrollment, PKCS#12-based certificate issuance, and web-based CSR submission for administrator enrollment. PKCS#12 (PFX) and CSR enrollment are supported against Microsoft CAs in the local forest, remote CAs—with or without trust relationships—and non-domain-joined Microsoft and EJBCA CAs.
  - Web APIs—Keyfactor Command is implemented with a robust and continually growing set of APIs that allow integration of Keyfactor Command functionality with the set of Keyfactor Command clients and orchestrators, as well as third-party or customer-created software or scripts.
- App Tier:
  - Event History and Audit Logging—Keyfactor Command maintains a record of operations that are performed on a certificate and the individual who performed the operation. This includes information such as initial synchronization date, additions to and removals from certificate stores, certificate recovery, and certificate revocation.
  - Role-Based Policy Enforcement—Keyfactor Command offers a rich, role-based permissions model that allows you to create your own roles as needed within the Keyfactor Command Management Portal. Users can be assigned to roles based upon Active Directory group memberships or individually, and then each role can be assigned granular Keyfactor Command permissions such as report creation, certificate revocation or renewal, or metadata update.
  - Dashboard and Report Engine—Keyfactor Command contains a dynamic dashboard along with several built-in reports generated using the Logi Analytics Platform.
  - Certificate Query & Collections—Keyfactor Command allows certificate administrators to query the certificate database using various search criteria. In addition, the bulk of Keyfactor Command's reporting and automated notification functionality can be driven through certificate collections, which are a user-definable mechanism that allows organizations to report on groups of certificates based on selection criteria.
  - Validation Service—The Keyfactor Command Validation Service implements a Keyfactor-patented vSCEP™ technology to validate the certificate request subject and, optionally, SAN(s) in a certificate requested based on a SCEP challenge.
  - Workflow Builder—The workflow builder in Keyfactor Command allows you to easily automate event-driven tasks when a certificate is requested or revoked. The workflows can be configured with multiple steps between the start and end of the operation that offer a simple way to configure notifications, approvals, and end-to-end automation. This provides for operational agility in an intuitive and easy-to-configure manner. The workflow builder is highly customizable with options to execute PowerShell

scripts, invoke REST requests, send email messages, and require one or more approvals built in, and facilities to build custom steps to allow many more functions to be built as needed.

  - Alert Notice Generator—Keyfactor Command allows you to configure customized email notifications for impending certificate expiration, revocation expiration, pending certificate requests, issued certificate requests and denied certificate requests. These notifications can be sent at configurable intervals, and may contain ASCII or HTML content, along with relevant information about the certificate or request in question (e.g. subject DN, issuer, thumbprint, template, custom metadata, etc.)
  - Certificate Request Alerting—Keyfactor Command provides interfaces through which administrators can request certificates that require CA-level manager approval, interfaces where the approvers can either issue or deny the certificate request, and interfaces where the requesters can then download the certificates. This, along with the notice generator, provides an end-to-end flow for certificate requests that require CA-level manager approval.
  - Alert Handlers—In addition to the notice generator that provides email alerts for SSH key and certificate expiration and enrollment workflow, Keyfactor Command also provides optional handlers that can be used in the certificate request and expiration alerts to output the information to the event log rather than sending it via email, run a PowerShell script, or automatically renew expiring certificates that are found in certificate store locations.
  - Keyfactor Command Service—The Keyfactor Command Service (a.k.a. the timer service) is designed to continually keep the Keyfactor Command SQL database synchronized with the contents of every configured Microsoft and EJBCA CA database in the organization as well as external certificates located on servers it can scan. The service can perform full or partial scans of different CAs at user-defined intervals. This enables a rapidly-accessible, easily queried mirror of CA database information that can then be put to use via Keyfactor Command. Synchronization of CA information is supported for Microsoft CAs joined to the local forest, remote domain-joined Microsoft CAs—with or without trust relationships—and non-domain-joined Microsoft and EJBCA CAs. The Keyfactor Command Service is also responsible for executing a variety of periodic tasks, including scheduled reports, alerts and cleanup jobs.

- Data Tier:
  - SQL Database—Keyfactor leverages a Microsoft SQL Server database to store the information that Keyfactor Command uses.
- Microsoft Certification Authority Components:
  - RFC 2818 Policy Handler—The RFC 2818 Policy Handler integrates with the Microsoft CA to allow you to automate the addition of a DNS SAN matching the CN of the requested certificate for selected templates.
  - SAN Attribute Policy Handler—The SAN Attribute Policy Handler allows the addition of SANs not included in the CSR when making a CSR enrollment request. The added SANs will overwrite any existing SANs in the CSR. This functionality is the same as that seen with the Microsoft default policy module for the CA as a whole when the CA EDITF_ATTRIBUTESUBJECTALTNAME2 flag is set except the SAN Attribute Policy Handler provides the ability to control SAN addition on a template-by-template basis without the need to enable the Microsoft CA EDITF_ATTRIBUTESUBJECTALTNAME2 flag.
  - vSCEP™ Policy Handler—The vSCEP™ Policy Handler integrates with the Microsoft CA and facilitates the enforcement of the Keyfactor-patented vSCEP™ technology mentioned above. This component is used to validate certificate request information for certificate requests submitted to the vSCEP API.
  - Whitelist Policy Handler—The Whitelist Policy Handler integrates with the Microsoft CA to allow you to restrict certificate enrollment on that CA for a configured certificate template or templates to only

designated client machines. This allows you, for example, to force certificate enrollment for web server certificates to be accepted only via the Keyfactor Command Management Portal and denied when coming from the Microsoft certificates MMC or IIS on the target servers for web server certificates.

- Enterprise Infrastructure:
  - Certification Authorities—Keyfactor Command has been built from the ground up to make it easier to operate organizational PKIs. This allows you to benefit from Keyfactor Command's extended features around Microsoft CA capabilities such as certificate templates, enrollment and recovery agents, and private key recovery. Keyfactor Command's integration with EJBCA provides support for capabilities such as certificate profiles, end entity profiles, enrollment, and revocation.
  - Microsoft Active Directory—Keyfactor Command is integrated with Microsoft Active Directory, using AD for authentication, supporting group memberships for Keyfactor Command Role assignments, using AD for Microsoft CA and certificate template enumeration, and for the inclusion of AD account attributes in the content of issued certificates.

4.2 Physical Architecture

Figure 433: Keyfactor Command Physical Architecture Diagram shows the physical architecture of the Keyfactor Command solution.

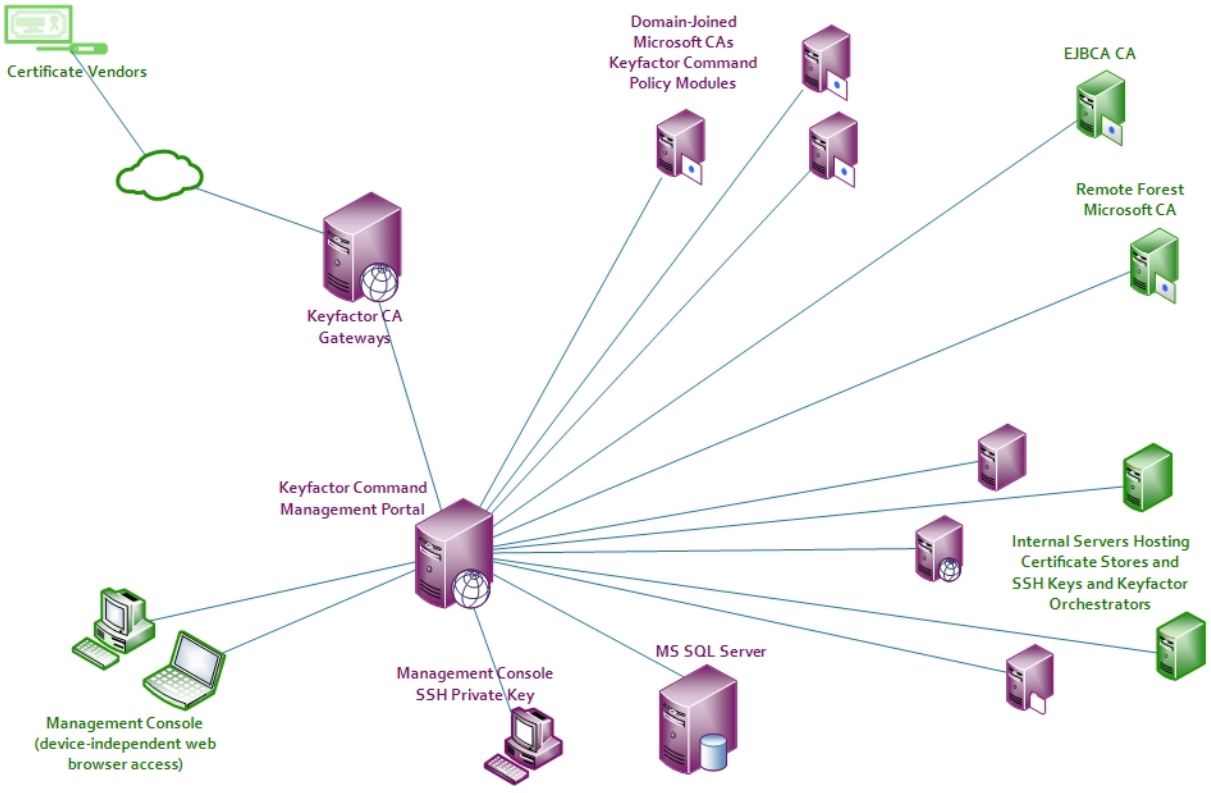

Figure 433: Keyfactor Command Physical Architecture Diagram

For simplicity, the servers in Figure 433: Keyfactor Command Physical Architecture Diagram are shown as single physical instances. In practice, these servers may be virtual machines and may be load balanced or clustered to

meet availability or performance requirements. The diagram includes some optional components—including the Keyfactor vendor gateways and Keyfactor orchestrators—which are not covered in this guide. For more information about these components, see the Installing Orchestrators on page 2355 guide and the documentation for each of the gateways.

- Keyfactor Command-Dedicated Servers[1]:
  - Keyfactor Command Server—This server hosts the Keyfactor Command Management Portal, the Keyfactor Command vSCEP™ and Services roles, and the Logi Analytics Platform for report generation. These roles run as ASP.NET (4.5 or higher) applications on IIS. Both Windows Server 2019 and 2022 are supported.
- Enterprise-Shared Servers:
  - Microsoft SQL Server—Keyfactor Command supports Microsoft SQL Server 2016 with cumulative update (CU) 2 or higher, 2017, 2019 and 2022 all with TLS encryption enabled for its primary database. While a dedicated SQL deployment is certainly an option, many organizations maintain a well-established SQL server farm to support multiple applications within the organization; if preferred, Keyfactor Command can easily make use of such a service. Keyfactor does not recommend locating the Keyfactor Command roles on the SQL server in a production deployment.
  - Web Reverse Proxy—If Internet-based access is required, the Keyfactor Command services can be published through a variety of reverse proxy products such as Microsoft UAG/TMG, F5, SiteMinder, or NetScaler.
  - Network-based Hardware Security Module (HSM not pictured)—In certain configurations, Keyfactor Command requires the use of Enrollment Agent (EA) and/or Key Recovery Agent (KRA) certificates. To provide additional security over these certificates' private keys, Keyfactor strongly recommends the use of a Hardware Security Module (HSM) such as the Thales NetHSM if these features will be used.

4.3 Solution Design

Keyfactor Command supports a number of different deployment architectures to help provide for different needs from small and simple to highly available. The solution can be as simple as one Keyfactor Command server hosting all the Keyfactor Command roles (other than the policy handlers, which are installed on a Microsoft CA) or the roles can be separated onto different machines to provide increased security or distribute the load. Redundant servers can be added to provide for high availability—either within the same data center or across data centers. Keyfactor expects that the specifics of a high availability deployment plan would be finalized as part of the project rollout.

[1]The roles described in this section may be co-located on a single physical or virtual server or may be further separated to multiple machines.

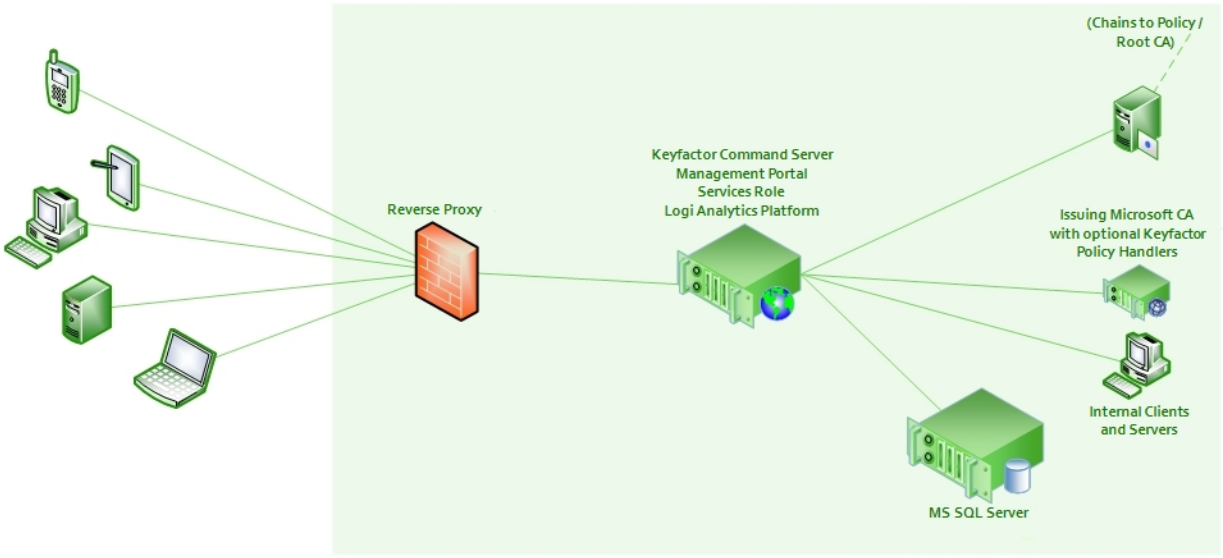

Figure 434: Simple Keyfactor Command Solution Design

4.4 Keyfactor Command Server

The Keyfactor Command solution by Keyfactor allows you to issue and manage certificates across enterprise infrastructures to allow you to achieve end-to-end visibility, control, and automation across all your machine identities so you can turn the impossible into the possible.

4.4.1 System Requirements

Table 758: System Requirements provides the recommendations for minimum system specifications used by Keyfactor Command components. All servers may be deployed as virtual machines and may be part of a clustering or load-balanced architecture, if desired. If the Keyfactor Command roles are co-located, the specifications may need to be scaled accordingly. All Microsoft-supported methods for making SQL Server highly available are supported. For most high availability requirements, Keyfactor recommends using always on availability groups (see SQL Server on page 2220).

As of Keyfactor Command version 10.0, connectivity to the SQL server requires TLS encryption. For information about configuring TLS for SQL server, see:

> https://docs.microsoft.com/en-us/sql/database-engine/configure-windows/enable-encrypted-connections-to-the-database-engine?view=sql-server-ver15

As of Keyfactor Command version 10.0, Windows Server 2016 is no longer supported. The installer will not check your server version nor prevent installation, but the product will not function properly. If you choose to use Server 2016, any PFXs will need to be configured to use SHA1 and 3DES for encryption for use by Keyfactor Command.

Table 758: System Requirements

Component	Minimum Requirements
Keyfactor Command Server (Management Portal, vSCEP™ and Services roles)	Windows Server 2019 or 2022 Internet Information Services (IIS) with Basic Authentication, Windows Authentication, ASP.NET 4.7 or greater, and the Active Directory Module for Windows PowerShell (see Install IIS and .NET on the Keyfactor Command Server on page 2241) .NET Framework 4.7.2 or greater 4 GB RAM, 2 GHz CPU, 40 GB disk
Microsoft SQL Database	Microsoft SQL Server 2016 with cumulative update (CU) 2 or higher, 2017, 2019, 2022 all with TLS encryption enabled and compatibility level 130 or higher. 8 GB RAM, 2+ GHz CPU (>= 2 cores), 500 GB disk
Browser to Access the Management Portal	Chrome 65.0.3325+, Firefox 59.0+, or Microsoft Edge 42.17134+
Keyfactor Command Server Upgrade	Keyfactor Command version 6.1.0 or later is required to upgrade to Keyfactor Command version 9.0 or later.
EJBCA CA	EJBCA Enterprise version 7.8.1 or later is supported. The EJBCA REST API must be enabled to interoperate with Keyfactor Command (see System Configuration -> Protocol Configuration in the EJBCA administration portal).

Tip: To check the compatibility level of the database, run the query:

```
SELECT name, compatibility_level FROM sys.databases
```

The value returned for compatibility_level should match the version of SQL server you are using for your Keyfactor Command database(s). If this needs to be updated, take a backup before updating the compatibility level via SQL query. For example, to update to compatibility_level 150 (SQL 2019):

```
ALTER DATABASE [KeyfactorDB] SET COMPATIBILITY_LEVEL = 150
```

Where [KeyfactorDB] is the name of your Keyfactor Command database and the compatibility_level value matches the version of SQL server you are using.

For more information, see:

https://docs.microsoft.com/en-us/sql/t-sql/statements/alter-database-transact-sql-compatibility-level?view=sql-server-ver15

4.4.2 Planning & Preparing

Before you install Keyfactor Command, you need to consider the components that make it up and its dependencies and decide where you want each role to reside, which roles—if any—you want to be highly available, and which features you're going to enable. It's possible to start with a non-redundant implementation and then add redundancy at a later time, but it's best to plan ahead for this if it's the desired goal.

Your license for Keyfactor Command may not include all the roles described in this document, so some sections of this guide may not apply to your implementation.

Once you've made these planning decisions, you then need to follow the steps outlined in this section that need to be taken prior to a Keyfactor Command implementation to install the prerequisites, create the required supporting components, and gather the necessary information to complete the Keyfactor Command installation and configuration process.

4.4.2.1 Certificate Authorities

In most cases, if you are installing Keyfactor Command then you have at least one Microsoft or EJBCA Certificate Authority (CA) in your environment. As you're planning for Keyfactor Command, you'll need to make the following decisions about the CA(s) and certificate templates for your environment:

- Which CAs should be synchronized to the Keyfactor Command database?

  Your license may not allow you to synchronize all of your CAs. Certificates belonging to offline root or policy CA "chain" certificates can be monitored without impacting your license.

  > **Note:** As of version 9.0, Keyfactor Command has implemented a constraint that prevents any two certificate authorities from having the same logical name and host name combination. Think about the logical name and host name configuration of the CAs that will be implemented with Keyfactor Command and check for duplicates.

- If you have Microsoft CAs, what authorization method will you use to configure the CAs (see Grant the Keyfactor Command Users and Service Account(s) Permissions on the CAs on page 2308)?
- If your Keyfactor Command license includes certificate enrollment:
  - Which CA(s) will be used to issue certificates based on CSRs through the Keyfactor Command Management Portal?
  - Which CA(s) will be used to issue PFXs through the Keyfactor Command Management Portal?
  - Which certificate template(s) will be configured for CSR enrollment in the Keyfactor Command Management Portal? In most cases, these templates will already exist.
  - Which certificate template(s) will be configured for PFX enrollment in the Keyfactor Command Management Portal? In most cases, these templates will already exist.
- If your Keyfactor Command license includes Mac auto-enrollment, which CA(s) will be used to automatically issue certificates to Macs running the Mac auto-enrollment agent?

  As part of the Keyfactor Command installation preparation, you may need to create a certificate template for this purpose.

Tip: This information is not needed to complete the initial installation and configuration, but will be needed to do post-installation configuration in the Keyfactor Command Management Portal.

4.4.2.2 SQL Server

Keyfactor Command uses a Microsoft SQL Server[1] database to store configuration and synchronized certificate information. Standard edition or above of SQL Server is required. In a production implementation, Keyfactor recommends that SQL Server be installed on a separate server from the Keyfactor Command roles.

Although you can implement a SQL server especially for Keyfactor Command, in many environments an existing shared SQL server or cluster is used. Keyfactor Command creates one database with a user-defined name and can successfully co-exist with other databases in the same SQL instance.

SQL should be installed with a case-insensitive collation setting.

Note: Microsoft SQL 2016 CU2, 2017, 2019, and 2022 all with TLS encryption enabled are supported.

Connecting to SQL over SSL

By default, Keyfactor Command connects to SQL using an encrypted connection. This requires configuration of an SSL certificate on your SQL server.

If your SQL server is not configured correctly for SSL, you'll see an error message similar to the following when you try to make a connection from Keyfactor Command:

```
Unable to establish a connection to the database server. Please ensure that the server name
is correct and sufficient privileges have been granted to the connection account.:
Encountered an invalid or untrusted certificate and could not connect to the database.
TLS encryption is enabled by default. Please visit 'Planning and Preparing --> SQL Server'
In the Keyfactor Installing Server guide to resolve this.
```

Log message will look something like:

```
2022-09-09 11:35:13.0142 CSS.CMS.Install.ConfigurationWizard.ViewModels.DatabaseViewModel [Error] -
Unable to establish a connection to the database server.  Please ensure that the server name is
correct and sufficient privileges have been granted to the connection account.
2022-09-09 11:35:13.0142 CSS.CMS.Install.ConfigurationWizard.ViewModels.DatabaseViewModel [Error] -
Encountered an invalid or untrusted certificate and could not connect to the database. TLS encryption
is enabled by default. Please visit 'Planning and Preparing --> SQL Server' in the Keyfactor
Installing Server guide to resolve this.
at CSS.CMS.Install.ConfigurationWizard.ViewModels.DatabaseViewModel.a(Object A_0, RunWork-
erCompletedEventArgs A_1)
A connection was successfully established with the server, but then an error occurred during the
```

[1]Microsoft SQL Server 2016 with cumulative update (CU) 2 or higher, 2017, 2019, 2022 all with TLS encryption is supported.

```
login process. (provider: SSL Provider, error: 0 - The certificate chain was issued by an authority
that is not trusted.)
```

To acquire a new SSL certificate or check for an existing certificate, see Using SSL to Connect to SQL Server on the next page.

If you would prefer not to use an encrypted channel for your connection to SQL, see Configurable SQL Connection Strings on page 2226.

Database Encryption

Keyfactor Command uses Microsoft SQL Server column encryption with the ENCRYPTBYKEY and DECRYPTBYKEY cryptographic functions to protect sensitive data. The type of data protected in this way includes:

- Service account credentials
- SMTP credentials
- Certificate store passwords
- Certificate and pending certificate request private keys
- API secrets
- The 64-byte key used to sign audit log records

SQL encryption is built in to the product and cannot be disabled. In addition to SQL encryption, Keyfactor Command offers optional application-level encryption. This option allows you to encrypt select sensitive data stored in the Keyfactor Command database using a separate encryption methodology utilizing a Keyfactor Command-defined certificate on top of the SQL server encryption. This additional layer of encryption protects the data in cases where the SQL Server master keys cannot be adequately protected. For more information, see Application-Level Encryption on page 2239.

Database Backup

Backup of the SQL server Database Master Key (DMK) for the Keyfactor Command database is of critical importance in database backup and recovery operations. The backup file of the DMK and the password for it should be stored in a safe, well-documented location. Without the file and password created with this process, some data that is encrypted within the Keyfactor Command database will be unrecoverable in a disaster recovery scenario. For more information, see SQL Encryption Key Backup on page 666 in the *Keyfactor Command Reference Guide*.

High Availability

For a highly available solution, Keyfactor recommends using always on availability groups. The availability groups feature of SQL Server sits on top of Windows Server failover clustering and provides the ability to automatically synchronize multiple copies of databases across geographically dispersed SQL Servers. Although the availability groups feature relies on Windows clustering, it does not require shared storage, so it is appropriate for a geo-redundant deployment. The availability groups feature is the current recommended solution from Microsoft. Because Keyfactor Command makes use of SQL database encryption, when availability groups are configured, the

Keyfactor Command service master key (SMK) must be synchronized between all participating nodes in the availability group. This can be accomplished by backing up the SMK from one SQL server and restoring it to the other servers in the availability group. For more information, see SQL Encryption Key Backup on page 666 in the *Keyfactor Command Reference Guide*.

Using SSL to Connect to SQL Server

By default, Keyfactor Command connects to SQL using an encrypted connection using an SSL certificate configured on your SQL server.

You can check whether your SQL server has been configured with an SSL certificate in one of two ways:

SQL Server Configuration Manager

1. On the SQL server, open the SQL Server Configuration Manager and drill down under SQL Server Network Configuration to find *Protocols for [YOUR INSTANCE NAME]*.
2. Right-click on Protocols for [YOUR INSTANCE NAME] and choose **Properties**.
3. Check the Certificate tab of the Properties dialog to see if a certificate has been configured and is still valid. If your certificate has a friendly name, it will appear here listed in the dropdown by its friendly name.

Important: A certificate will only appear here if it has a CN[1], usually the FQDN of the SQL server. If a certificate has been configured without this, it will not appear to be configured through this UI.

[1]The Subject property of the certificate must indicate that the common name (CN) is the same as the host name or fully qualified domain name (FQDN) of the server computer or it must match the DNS suffix if using a wildcard certificate. When using the host name, the DNS suffix must be specified in the certificate. If SQL Server is running on a failover cluster, the common name must match the host name or FQDN of the virtual server and the certificates must be provisioned on all nodes in the failover cluster.

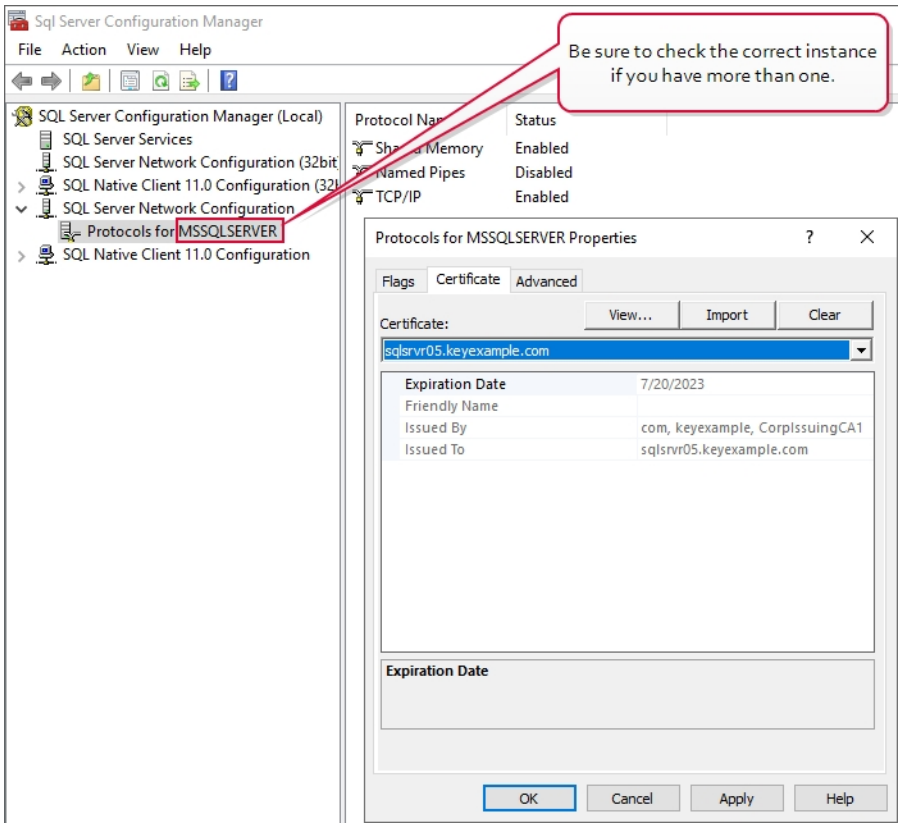

Figure 435: SQL Server Configuration Manager View Active SSL Certificate

Registry

1. On the SQL server, open the registry editor and browse to (where *[MSSQL15.MSSQLSERVER]* is the correct version of SQL server for your server):

   ```
   HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Microsoft SQL Server\
   [MSSQL15.MSSQLSERVER]\MSSQLServer\SuperSocketNetLib
   ```

2. In the SuperSocketNetLib registry key, look for a Certificate value.

3. Validate that the Certificate value has a thumbprint configured. This should match the thumbprint of an active certificate with a Server Authentication EKU in the Local Machine certificate store.

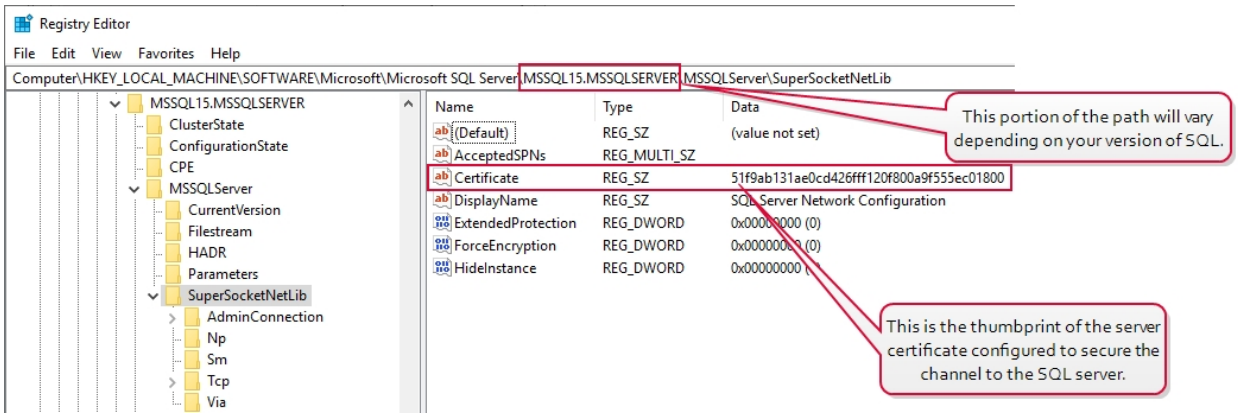

Figure 436: Registry View Active SSL Certificate

To acquire a new certificate for your SQL server:

1. On the SQL server open the Services.msc MMC and scroll down to locate the *SQL Server ([YOUR INSTANCE NAME])* service.

2. Check the *Log On As* column for the name of the service account that the service is running as.

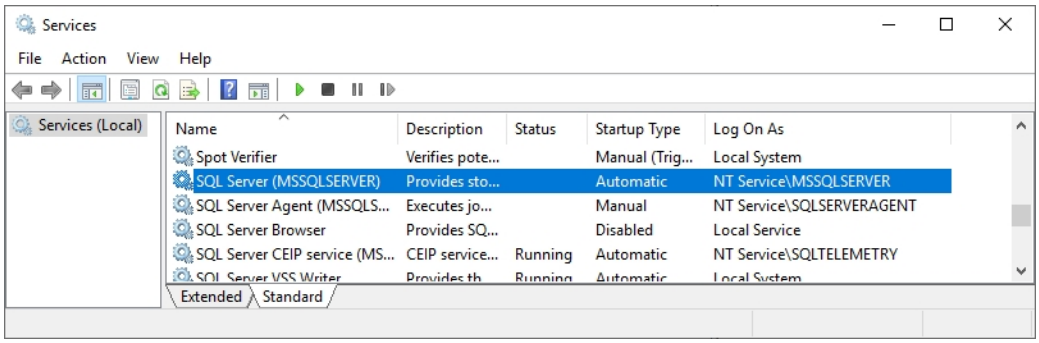

Figure 437: View SQL Server Services

3. Identify a template with a Server Authentication EKU (a typical web server template).

4. On the SQL server, do one of following:
    - Using the GUI:
        a. Open an empty instance of the Microsoft Management Console (MMC).
        b. Choose **File->Add/Remove Snap-in…**.
        c. In the *Available snap-ins* column, highlight **Certificates** and click **Add**.
        d. In the Certificates snap-in popup, choose the radio button for Computer account, click **Next**, accept the default of Local computer, and click **Finish**.
        e. Click **OK** to close the Add or Remove Snap-ins dialog.

- Using the command line:
    a. Open a command prompt using the "Run as administrator" option.

    b. Within the command prompt type the following to open the certificates MMC:
    certlm.msc

5. Enroll for the certificate using your preferred method, being sure to give the certificate a CN (it will not appear in the configuration tool without this) and add subject alternative names (SANs) to it for all the IP addresses, server names, and FQDNs that you might use to reference the SQL server when communicating with it, including DNS aliases. Install it, along with its private key, into the Local Machine certificate store on the SQL server. One way to do this is in the certificates MMC:
    a. Drill down to the Personal folder under **Certificates** for the Local Computer, right-click, and choose **All Tasks->Request New Certificate…**.

    b. Follow the certificate enrollment wizard, selecting the template you identified for this purpose, and providing appropriate SANs along with any required information.

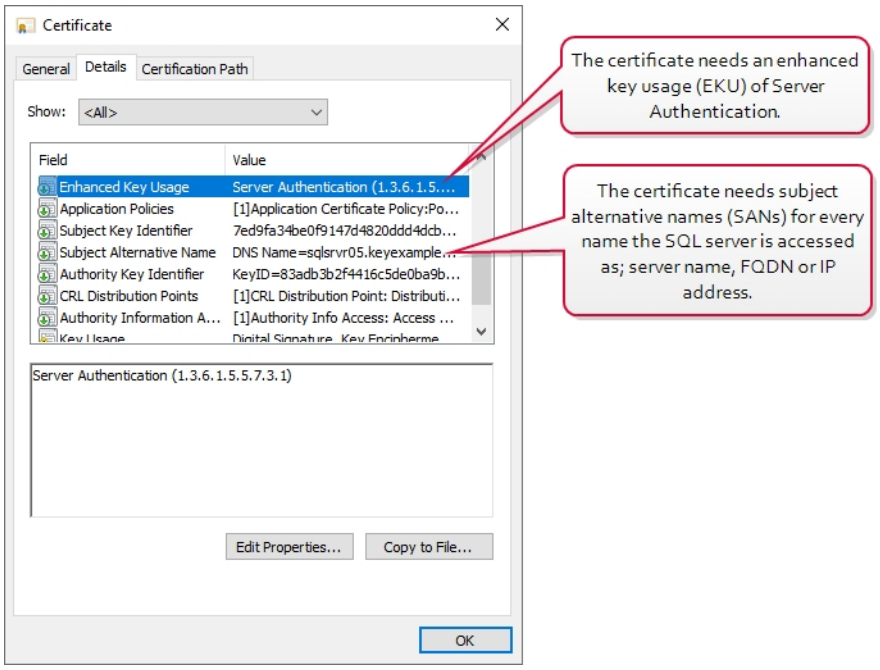

Figure 438: SQL Server SSL Certificate Details

6. Drill down to the Personal folder under **Certificates** for the Local Computer, locate your certificate, right-click, and choose **All Tasks->Manage Private Keys…**.

7. In the Permissions for private keys dialog, click **Add**, add the SQL service account, and grant that service account **Read** but not **Full control** permissions. If the SQL server is running as *NT Service\ [YOUR INSTANCE NAME]* as shown in Figure 437: View SQL Server Services, be sure to change the location to your local machine and enter the object name as "NT SERVICE\[YOUR INSTANCE NAME]" as shown in Figure 439: Grant Private Key Permissions for SQL Server.

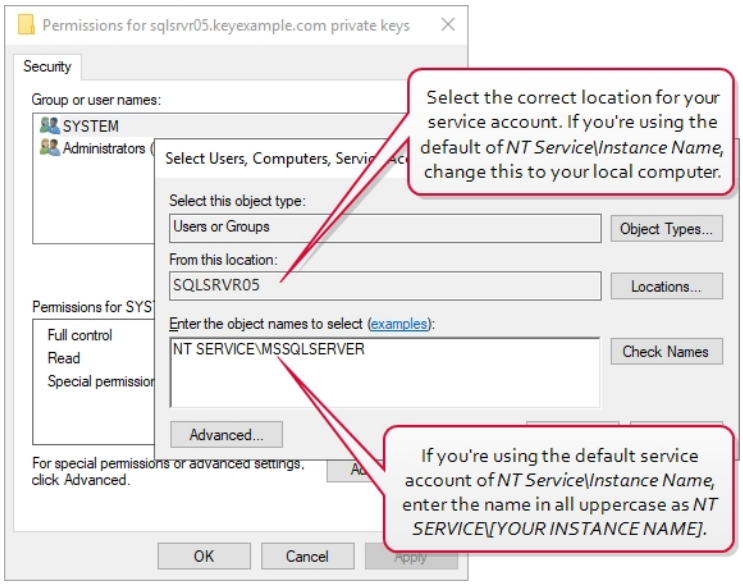

Figure 439: Grant Private Key Permissions for SQL Server

8. Click **OK** to save.
9. Configure the SSL certificate in SQL using either the SQL Server Configuration Manager or registry as shown above for checking whether there is an existing certificate configured (see SQL Server Configuration Manager on page 2222).
10. After you've acquired a new certificate, made the private key permission changes, and associated it in SQL, you'll need to restart the *SQL Server (Instance Name)* service (see Figure 437: View SQL Server Services) before these changes will take effect.

Configurable SQL Connection Strings

Keyfactor Command supports using a "template" SQL connection string that can be created to fit the needs of the overall deployment. This template will be used as a starting point and will not be overwritten by the configuration wizard. For instance, you can set the timeout setting in one place, and once the configuration wizard is run, this is reflected in all places where a connection string is used. The template can be changed at any time to update the connection strings.

To create a customized connection string, after installing the Keyfactor Command software but before running the configuration wizard, modify both the EFModels and SqlDirect connection strings in the **SharedSqlConnectionStrings.config** file found in the*Configuration* folder under your installation directory. By default, this is:

C:\Program Files\Keyfactor\Keyfactor Platform\Configuration

The settings that can be modified are described in the following Microsoft article:

https://docs.microsoft.com/en-us/dotnet/api/system.data.sqlclient.sqlconnection.connectionstring?view=dotnet-plat-ext-6.0

Note: The *Data Source*, *Initial Catalog*, *Integrated Security*, *User ID* and *Password* settings are reserved for the configuration wizard to use to configure and save the authentication for the connection string, but other settings found in the template string are left as-is.

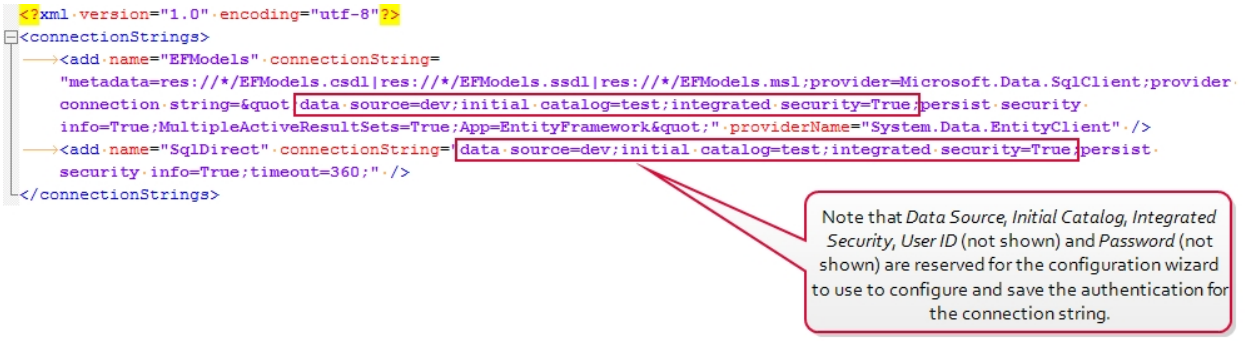

Figure 440: Default SQL Connection Strings

If you prefer to connect to your SQL server over a non-encrypted channel (and thus avoid configuring an SSL certificate for your SQL server), you can use the *Encrypt* keyword in the connection strings with a value of *False*.

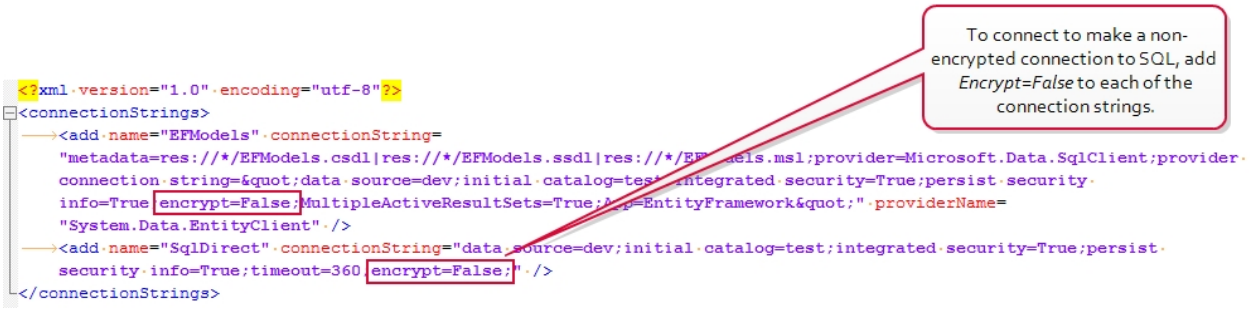

Figure 441: SQL Connection Strings with Encrypt Channel Disabled

4.4.2.3 Keyfactor Command Server(s)

A Keyfactor Command server implementation is made up of several Keyfactor Command roles:

Keyfactor Command Management Portal

The server with this role provides the web-based administration interface that is used to view and report on certificates issued in the environment and enroll for certificates. This role runs under Microsoft IIS. Configuration for the Keyfactor Command implementation as a whole is also done through the Keyfactor Command Management Portal. The Logi Analytics Platform for reporting is hosted on the server with this role.

This role is required on all Keyfactor Command servers.

Keyfactor Command Windows Services

The server with this role hosts back-end services required to support Keyfactor Command. This includes the Keyfactor Command Service, which is used for all periodic tasks throughout Keyfactor Command, including CA synchronization, monitoring alerts, and report automation.

This role is required on all Keyfactor Command servers.

Keyfactor Command Web API

The server with this role hosts the Web APIs—the newer Keyfactor API and the older Classic API. The newer Keyfactor API is also included in the Management Portal role, since the Management Portal makes extensive use of this API.

This role is optional. If you choose not to install this role, you will not be able to use the older Classic API. Only users with existing applications written using the Classic API typically need to install the Classic API.

Keyfactor Command Orchestrator Service API

The server with this role hosts the back-end service for receiving requests from and sending requests to Keyfactor agents and orchestrators.

This role is optional. If you choose not to install this role, you will not be able to use agents and orchestrators with Keyfactor Command.

Keyfactor Command vSCEP Validation Service

The server with this role hosts the back-end service for validating SCEP requests.

This role is optional. If you choose not to install this role, you will not be able to use Keyfactor's vSCEP validation technology to validate the certificate request subject and, optionally, SAN(s) in a certificate requested based on a SCEP challenge.

In many environments, the Keyfactor Command Management Portal, Windows Services, Web API, and Orchestrator Service API roles are collocated on a single server (or pair of servers if redundancy is desired). The vSCEP Validation Service is an optional role that is only installed in environments where SCEP validation is required. Both physical and virtual servers are supported.

Tip: See Install: Select Components on page 2255 for related information.

For a high availability (HA) solution using the same roles on all nodes, note that the following conditions apply:

- All servers must point to the same Keyfactor Command SQL database.
- All servers must be configured with the same encryption certificate AND the corresponding private key (see Database Tab on page 2260).
- Keyfactor recommends that the Keyfactor Command Service be configured to run all services on each node. This allows the service to manage the jobs most efficiently—the service will check out jobs via a locking mechanism that will enforce that any jobs are running on only one service at a time. However, you do have the

option to manually tune the jobs on the servers if desired (such that server A always does jobs 1, 2 and 3 and server B always does jobs 4, 5 and 6).

- Review load balancing rules and configuration, if applicable. Load balancing configuration is beyond the scope of this guide.

Keyfactor does not recommend installing the Keyfactor Command Management Portal, Windows Servers, Web API, Orchestrator Service API, or vSCEP Validation Service role on a CA or on a SQL server in a production environment.

As you plan for Keyfactor Command, you need to decide upon an architecture for the implementation and prepare servers with sufficient resources accordingly. See System Requirements on page 2217 for more information about planning for servers with sufficient resources to support the planned roles.

Licensing

The Keyfactor Command product is licensed by component. Your license for Keyfactor Command may not include all the features described in this guide. If you choose to add additional components to your Keyfactor Command license in the future, these features can generally be configured without the need to reinstall Keyfactor Command.

4.4.2.4 Create Active Directory Service Accounts for Keyfactor Command

Several of the Keyfactor Command roles operate under an Active Directory service account. You can either create a single Active Directory service account for all these roles or create separate service accounts for each role. If multiple Keyfactor Command roles will be installed on the same server, some of the below roles will be redundant. The roles that require a service account are:

Keyfactor Command Installer

The user who runs the Keyfactor Command installation must have local administrator permissions on the Keyfactor Command server(s) and must be granted permissions in SQL if Windows authentication for SQL will be used during the installation (see Grant Permissions in SQL on page 2241). You can either grant these permissions to an existing user or you can create a Keyfactor Command installer account and grant the appropriate permissions to this account.

Additionally, the user installing Keyfactor Command must have the SeBackupPrivilege and SeRestorePrivilege rights on the Keyfactor Command server. Normally, administrators are granted these permissions by default, but you should confirm the permissions prior to starting the install. These permissions can be set through Group Policy or Local Security Policy, and can be found under "Local Policies\User Rights Assignment" as "Back up files and directories" and "Restore files and directories".

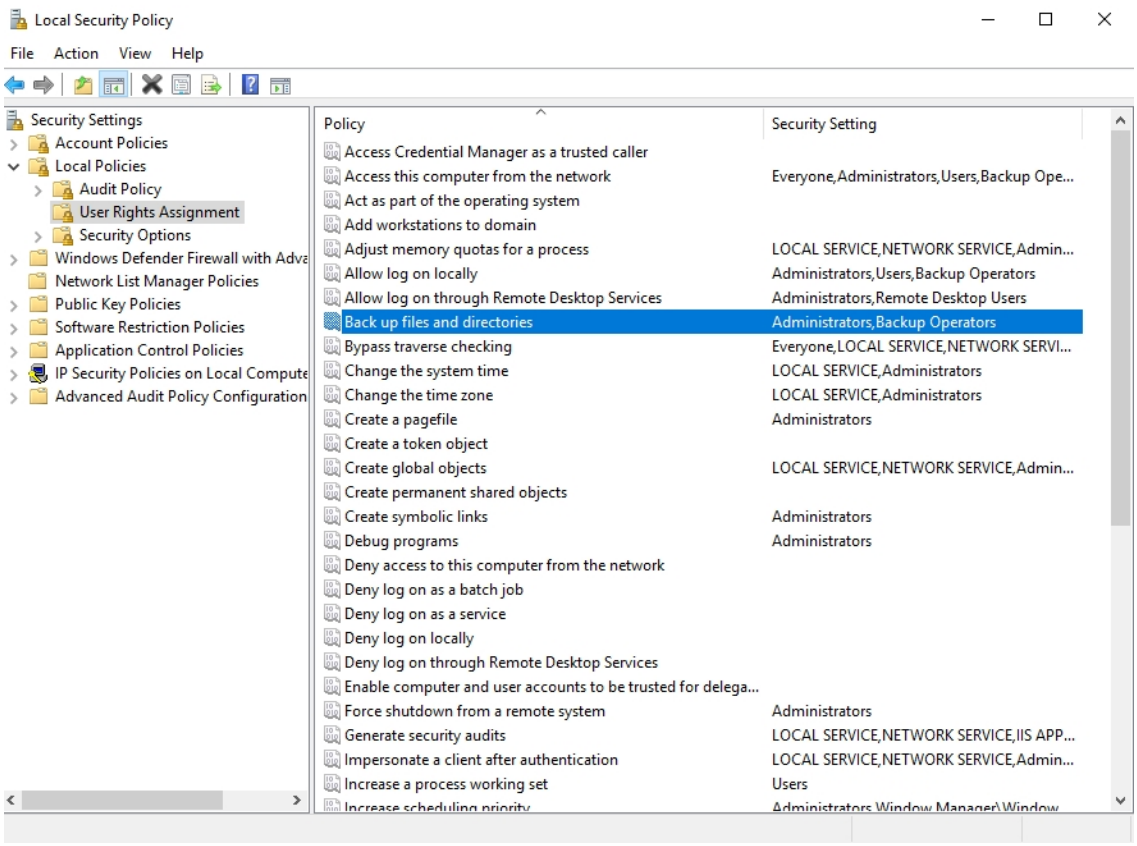

Figure 442: Local Security Policy

For more information on this from Microsoft, see:

https://docs.microsoft.com/en-us/windows/win32/api/userenv/nf-userenv-loaduserprofilea#remarks

Keyfactor Command Service

The Keyfactor Command Service (a.k.a. the timer service) runs on the Keyfactor Command services server. It synchronizes certificates to the SQL database and initiates notification and reporting tasks. This service runs in the context of an Active Directory Service account.

The user with this role will be granted permission on each of the SQL schemas (dbo, ssl, ssh, cms_agents, etc.) and permission on the encryption certificate in SQL through the keyfactor_db_role which is created during configuration.

The user with this role must have the "Log on as a service" right on the Keyfactor Command server. Normally, this permission is granted automatically as part of the installation process. You can confirm the permissions through Group Policy or Local Security Policy in "Local Policies\User Rights Assignment". Validate that the user associated with the Keyfactor Command Service has been added to "Log on as a service" directly or indirectly (via group membership).

The user with this role needs to be able to create log files and write to them. During installation, this permission is granted by granting "Create files / write data" and "Create folders / append data" permissions on the log directory

(C:\Keyfactor\logs) to the local users group on the assumption that the local users group will contain either "NT AUTHORITY\authenticated users" or "DOMAIN\Domain Users" and that the service account user will be granted permissions via at least one of these. If this is not the case, permissions for the service account user will need to be granted manually to the log directory.

The user with this role needs to be granted permissions on any certificate authorities from which certificates will be synchronized. Additional certificate authority permission may be needed depending on the features that will be used. For more information, see Grant the Keyfactor Command Users and Service Account(s) Permissions on the CAs on page 2308.

Keyfactor Command Management Portal (Application Pool)

The Keyfactor Command Management Portal uses an application pool under IIS to operate. This application pool runs in the context of an Active Directory service account.

The user with this role will be granted permission on each of the SQL schemas (dbo, ssl, ssh, cms_agents, etc.) and permission on the encryption certificate in SQL through the keyfactor_db_role which is created during configuration.

The user with this role must have the "Log on as a batch job" and "Impersonate a client after authentication" rights on the Keyfactor Command server. In a typical IIS installation, these rights are granted to the IIS_IUSRS group and the user running any application pool created in IIS inherits these rights without being added to the IIS_IUSRS group. For more information about the IIS_IUSRS group, see:

> https://learn.microsoft.com/en-us/iis/get-started/planning-for-security/understanding-built-in-user-and-group-accounts-in-iis

You can confirm the permissions or set them manually for the application pool user through Group Policy or Local Security Policy in "Local Policies\User Rights Assignment". Validate that either the IIS_IUSRS group or the user associated with the Keyfactor Command application pool has been added to "Log on as a batch job" and "Impersonate a client after authentication" directly or indirectly (via group membership).

The user with this role needs to be able to create log files and write to them. During installation, this permission is granted by granting "Create files / write data" and "Create folders / append data" permissions on the log directory (C:\Keyfactor\logs) to the local users group on the assumption that the local users group will contain either "NT AUTHORITY\authenticated users" or "DOMAIN\Domain Users" and that the service account user will be granted permissions via at least one of these. If this is not the case, permissions for the service account user will need to be granted manually to the log directory.

The user with this role needs to be granted permissions on any certificate authorities from which certificates will be synchronized. Additional certificate authority permission may be needed depending on the features that will be used. For more information, see Grant the Keyfactor Command Users and Service Account(s) Permissions on the CAs on page 2308.

Note: The Application Pool account must have read permission on any groups being created. This will allow Keyfactor Command to query for group membership on the groups.

Logi Report Access

If Basic authentication will be used to access the Keyfactor Command Management Portal, the Logi Analytics Platform uses a service account to allow Logi to connect to Keyfactor Command via the Keyfactor API to display the dashboard information. This service account is not required if integrated Windows authentication will be used for the Management Portal. The Keyfactor Command analytics application for dashboard and reporting uses an application pool under IIS to operate. This application pool runs in the context of an Active Directory service account. This role is collocated with the Management Portal; a separate service account for this role is not needed as a single application pool will be used for both.

Keyfactor Command Orchestrators API

The Keyfactor Command Orchestrators API IIS application accepts connections from Keyfactor Command orchestrators and uses an application pool under IIS to operate. This application pool runs in the context of an Active Directory service account. If this role will be installed on the server hosting the Keyfactor Command Management Portal role, a separate service account for this role is not needed as a single application pool will be used for both.

Keyfactor Command Keyfactor API

The Keyfactor Command Keyfactor API uses an application pool under IIS to operate. This application pool runs in the context of an Active Directory service account. The Keyfactor API is an integral part of Keyfactor Command and is not an optional installation. The Keyfactor API can be configured to support custom applications. If the Keyfactor Command Keyfactor API role will be installed on the server hosting the Keyfactor Command Management Portal role, a separate service account for this role is not needed as a single application pool will be used for both.

Keyfactor Command Classic API

The Keyfactor Command Classic API (the classic or legacy API) uses an application pool under IIS to operate. This application pool runs in the context of an Active Directory service account. The Keyfactor Command Classic API may have been configured to support custom applications in previous versions of Keyfactor Command. If the Keyfactor Command Classic API role will be installed on the server hosting the Keyfactor Command Management Portal role, a separate service account for this role is not needed as a single application pool will be used for both.

EJBCA End Entity for EJBCA CA Access

Keyfactor Command supports synchronization of certificates and certificate enrollment from EJBCA certificate authorities by configuring a client certificate issued from the EJBCA CA on the CA record in the Management Portal. This client certificate needs to be associated with an end entity in EJBCA that can be assigned sufficient permissions to perform all necessary CA tasks from Keyfactor Command.

Explicit Credentials for Microsoft CA Access

Keyfactor Command supports synchronization of certificates and certificate enrollment from Microsoft certificate authorities in remote forests (forests other than the forest in which Keyfactor Command is installed which are not in a two-way trust with the Keyfactor Command forest) by configuring a service account from the forest in which the CA resides on the CA record in the Management Portal. All communication to retrieve existing certificates, enroll for new certificates, revoke certificates, and recover certificate keys from the remote CA is done in the context of this service account. Explicit credentials for remote CA access is configured in the Keyfactor Command

Management Portal after installation is complete rather than in the configuration wizard.

You may need additional service accounts to support the use of Keyfactor Command orchestrators and/or gateways in your environment. Please see:

- Create Service Accounts for the Universal Orchestrator on page 2362 in the *Keyfactor Orchestrators Installation and Configuration Guide*
- Create a Service Account for the Keyfactor Bash Orchestrator on page 2435 in the *Keyfactor Orchestrators Installation and Configuration Guide*
- Create Service Accounts for the Java Agent on page 2412 in the *Keyfactor Orchestrators Installation and Configuration Guide*
- The installation guide for each gateway.

The service account(s) need to be created in Active Directory prior to installation of the Keyfactor Command software, and the person installing the Keyfactor Command software needs to know the service account(s) domain, username and password. The same service account may be used for multiple roles, if desired. For example, you might have one service account for orchestrators, another for gateways, and a third for all server roles.

Table 759: Typical Service Accounts

Account	Uses
Keyfactor Command Service Account	Keyfactor Command Service, Keyfactor Command Management Portal (Application Pool), Keyfactor Command APIs, Keyfactor Command Logi Report Access
Keyfactor Orchestrator Service Account	Keyfactor Orchestrator access to Keyfactor Command Server and Keyfactor Orchestrator on-machine operations, where applicable

4.4.2.5 Create Active Directory Groups to Control Access to Keyfactor Command Features

Keyfactor Command uses Active Directory groups to control access to the various Keyfactor Command features. The Keyfactor Command Management Portal supports multiple groups with different levels of access to the portal. During the installation, at least one group or user must be entered to grant full administrative access to the portal. After installation, additional groups can be configured through the Keyfactor Command Management Portal to grant more limited access to the portal.

Important: The built-in Active Directory groups Domain Admins and Enterprise Admins cannot be used directly to grant access to the Management Portal due to how these groups function within Windows. You can create a custom Active Directory group, reference that group in the Management Portal, and add the built-in Domain Admins or Enterprise Admins group to that custom group, if desired.

Groups that you may find it useful to identify or add following the initial installation include:

Keyfactor Command Enrollment

Users who are a member of this group or groups may use PFX and/or CSR enrollment through the Keyfactor Command Management Portal. Access control for enrollment is configured in the Keyfactor Command Management Portal after installation is complete.

Keyfactor Command My SSH Key

Users who are a member of this group or groups may acquire SSH keys through the Keyfactor Command My SSH Key portal. Access control for the My SSH Key portal is configured in the Keyfactor Command Management Portal after installation is complete.

Keyfactor Java Agents

Service accounts that are a member of this group are allowed to auto-register as Java agents in Keyfactor Command, if auto-registration is configured, providing for more hands-free management of Java and PEM certificate stores. This group is not required if auto-registration with user validation will not be used.

Keyfactor Bash Orchestrators

Service accounts that are a member of this group are allowed to auto-register as Bash orchestrators in Keyfactor Command, if auto-registration is configured, providing for more hands-free management of Bash orchestrators. This group is not required if auto-registration with user validation will not be used.

Keyfactor Mac Auto-Enrollment Users

Users who are members of this group are allowed to auto-register for Mac auto-enrollment in Keyfactor Command, if auto-registration is configured, providing for more hands-free management of Mac auto-enrollment. The same group may be used to grant users permissions on the template that will be used for Mac auto-enrollment. This group is not required if auto-registration with user validation will not be used and a different group will be used to grant permission on the template.

Note: The same group may be used for multiple roles. Existing groups may be used. For example, if all employees of your organization are members of the Active Directory Domain Users group and you wish to allow all employees to acquire SSH keys, you may use the Domain Users group for the Keyfactor Command My SSH Key function.

Tip: To grant access in the Management Portal to users from trusted forests, create a domain local group in the Active Directory domain in which Keyfactor Command is installed, put the cross-forest users and groups in this local group and grant access in Keyfactor Command to this domain local group.

4.4.2.6 Configure Certificate Chain Trusts for CAs

The Keyfactor Command server needs to trust the chain certificates for all the CAs you will reference within Keyfactor Command in order for all operations to complete successfully. In many environments, root and intermediate trusts for domain-joined Microsoft CAs are pushed out automatically. If this is not the case in your

environment or if you are using EJBCA CAs, you will need to configure these chain trusts on the Keyfactor Command server manually.

The certificate for each root CA must be installed in the Trusted Root Certification Authorities store under Local Computer on the Keyfactor Command server. If your public key infrastructure (PKI) also has issuing CAs, the issuing CA certificates must be installed in the Intermediate Certification Authorities store under Local Computer on the Keyfactor Command server.

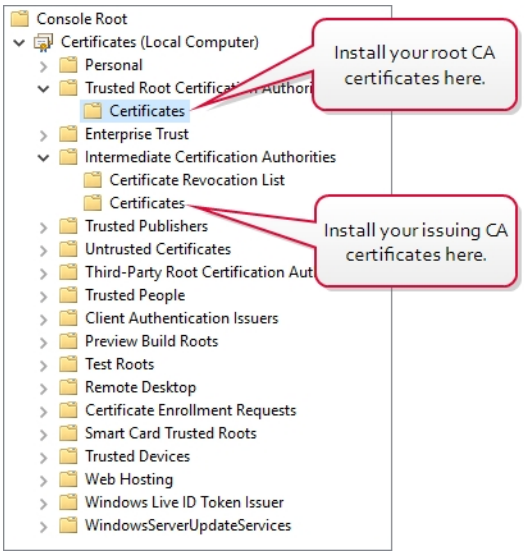

Figure 443: Install CA Chain Certificates on the Keyfactor Command Server

4.4.2.7 Hostname Identification and Resolution

Prior to the installation of Keyfactor Command, you need to determine the DNS alias(es) by which the Keyfactor Command roles will be accessed, if any, and configure them in your hostname resolution solution so that they will be resolvable prior to installation. For example, if you're licensed for SSH key management and wish to publish the My SSH Key portal externally to support SSH key acquisition by users outside the company firewall, you will probably wish to reference the server by a DNS alias rather than its actual hostname. For example, you may wish to use keyfactor.keyexample.com rather than websrvr23.keyexample.local. This is particularly significant if you will be using redundant servers with load balancing. For DNS aliases used internally, you will need to consider whether the servers to be accessed will be authenticated using Kerberos authentication. Out of the box, the Keyfactor Command Management Portal uses integrated Windows authentication and will default to Kerberos authentication in most environments. Although some features of the Keyfactor Command Management Portal may support NTLM authentication in some environments, the dashboard and enrollment functions do not support NTLM. If you will be using Kerberos authentication, your DNS aliases need to be configured as "A" records rather than CNAME records because Kerberos does not function well with CNAME records under Microsoft IIS.

The roles for which you need hostnames during the Keyfactor Command installation are:

SQL Server

For a small environment you may choose to use the server's actual name. If you plan to use SQL clustering, you will need an alias that represents the cluster. Using an alias for the SQL server allows for database portability in the future.

Email

During the Keyfactor Command installation you configure the email server that will be used to send email notifications.

Keyfactor Command Management Portal

This is the primary management server and may hold all Keyfactor Command roles in a small implementation.

Keyfactor Command Logi Dashboard and Reports

This hostname must match the hostname entered for the Management Portal.

Keyfactor Command vSCEP Service

This hostname is only required if your Keyfactor Command license includes vSCEP™. If all Keyfactor Command roles are combined on one server, this will be the same hostname as used for the Keyfactor Command Management Portal.

Keyfactor Command Orchestrators API

This hostname is only required if your Keyfactor Command license includes orchestrator functionality. If all Keyfactor Command roles are combined on one server, this will be the same hostname as used for the Keyfactor Command Management Portal.

Keyfactor Command Keyfactor API

This hostname must match the hostname entered for the Management Portal unless you are installing a secondary instance of the Keyfactor API.

Keyfactor Command Classic API

This hostname is only required if you choose to enable this option for legacy support. Out of the box, the Keyfactor Command API PowerShell Client use the Classic API role. If all Keyfactor Command roles are combined on one server, this will be the same hostname as used for the Keyfactor Command Management Portal.

Centralized Logging Solution

This hostname is only required if you choose to enable the option to copy Keyfactor Command audit logs entries in real time, as they are generated, to a separate server for collection and analysis by a centralized logging solution (e.g. rsyslog, Logstash).

Prior to beginning the Keyfactor Command installation, ensure that the selected hostnames resolve successfully.

4.4.2.8 Firewall Considerations

Keyfactor Command needs to be able to communicate internally between the various Keyfactor Command components installed on different servers, if applicable, and to the SQL server, certificate authorities, centralized logging server (if applicable), and Active Directory. If there are any firewalls in the environment that control internal traffic, these may need to be updated to allow the appropriate level of communication. Table 760: Protocols Keyfactor Command Uses for Communication shows each Keyfactor Command component and the protocols they use to communicate. In addition, all Keyfactor Command components require a healthy Active Directory environment with the ability to use Kerberos, LDAP, and DNS.

Table 760: Protocols Keyfactor Command Uses for Communication

Keyfactor Command Component	Protocols and Ports	Target
Keyfactor Command Management Portal	HTTP/HTTPS (TCP 80/443)	Client browser (e.g. Microsoft Edge)
Keyfactor Command Management Portal	HTTP/HTTPS (TCP 80/443)	Certificate revocation list (CRL) distribution points
Keyfactor Command Management Portal	HTTP/HTTPS (TCP 80/443)	EJBCA Certificate Authorities
Keyfactor Command Management Portal	RPC/DCOM (TCP 135 plus random high ports typically in the range 49152 – 65535)	Microsoft Certificate Authorities
Keyfactor Command Management Portal	RPC/DCOM (TCP 135 plus random high ports typically in the range 49152 – 65535)	Keyfactor vendor gateways to cloud CAs (e.g. Entrust, Symantec)
Keyfactor Command Management Portal	MS SQL (default TCP 1433)	SQL Server
Keyfactor Command Management Portal	Varies depending on the implemented solution (TCP 514 for rsyslog, TCP 5000 for Logstash are some standard defaults)	Centralized logging solution
Keyfactor Command	Active Directory (TCP/UDP 389)	Microsoft Active Directory queries
Keyfactor Command SSH Management	Active Directory Web Services (TCP 9389)	Microsoft Active Directory for group membership enumeration
All Orchestrators and Agents	HTTP/HTTPS (TCP 80/443)	Keyfactor Command Orchestrator API endpoint
Keyfactor Windows	PowerShell Remoting (default TCP 5985 and 5986)	IIS Servers to which PFX files will

Keyfactor Command Component	Protocols and Ports	Target
Orchestrator (IIS Certificate Stores)		be distributed
Keyfactor Universal Orchestrator (IIS Certificate Stores)	PowerShell Remoting (default TCP 5985 and 5986)	IIS Servers to which PFX files will be distributed
Keyfactor Windows Orchestrator (SSL Endpoint Management)	Any configured for scanning	The SSL endpoint being scanned by the SSL discovery or monitoring job
Keyfactor Universal Orchestrator (SSL Endpoint Management)	Any configured for scanning	The SSL endpoint being scanned by the SSL discovery or monitoring job
Keyfactor Windows Orchestrator (F5 and NetScaler Certificate Store Management)	HTTP/HTTPS (TCP 80/443)	F5 or NetScaler Devices
Keyfactor Windows Orchestrator (Remote Certificate Authority)	RPC/DCOM (TCP 135 plus random high ports typically in the range 49152 – 65535)	Microsoft Certificate Authorities
Keyfactor Universal Orchestrator (Remote Certificate Authority)	RPC/DCOM (TCP 135 plus random high ports typically in the range 49152 – 65535)	Microsoft Certificate Authorities
Keyfactor Windows Orchestrator (FTP)	FTP (TCP 21)	FTP Servers
Keyfactor Universal Orchestrator (FTP)	FTP (TCP 21)	FTP Servers
Keyfactor Bash Orchestrator	SSH (TCP 22 by default)	Remote control targets for SSH management

Keyfactor Command Component	Protocols and Ports	Target
Keyfactor Gateways to Cloud CAs	HTTP/HTTPS (TCP 80/443)	Cloud providers (e.g. Entrust, Symantec)
Keyfactor Cloud Gateway	Active Directory Web Services (TCP 9389)	Microsoft Active Directory for group membership enumeration

4.4.2.9 Acquire a Public Key Certificate for the Keyfactor Command Server

Keyfactor recommends using HTTPS to secure the channel between clients and the Keyfactor Command server(s). This requires at least one SSL certificate. You will need an SSL certificate or certificates for each of the hostnames you have identified (see Hostname Identification and Resolution on page 2235).

Acquire the certificate(s) using the Fully Qualified Domain Name (FQDN) of the server or alias used for the Keyfactor Command server(s). For example:

```
keyfactor.keyexample.com
```

The certificate(s) may be installed on the Keyfactor Command server(s) prior to installation of the Keyfactor Command software or may be installed at the time of Keyfactor Command installation. See Configure SSL for the Default Web Site on the Keyfactor Command Server on page 2247 for more information.

If installed ahead of time, the certificate(s) should be placed in the Personal Certificate store of the Local Computer using the Certificates MMC Snap-In.

Application-Level Encryption

Keyfactor Command uses data encryption for sensitive data—such as private keys for certificates—stored in the Keyfactor Command database (see SQL Server on page 2220). This option encrypts only the data in the database deemed to be of a sensitive nature, not the entire database. By default, the data is encrypted using SQL encryption, but you have the option to add another level of security with application-level encryption. If you choose to enable this option, you will need a certificate for this purpose installed in the Personal Certificate store of the Local Computer on each Keyfactor Command server. The certificate must have a key usage of either key encipherment or data encipherment enabled. Microsoft certificate templates only allow you to configure data encipherment ("Allow encryption of user data") as a suboption to key encipherment ("Allow key exchange only with key encryption"). You do not need to enable both. You may use the certificate acquired in the name of the Keyfactor Command web site (assuming it supports the appropriate key usage) or you may enroll for a separate certificate for this purpose. The same certificate must be used on all Keyfactor Command servers and the certificate must be available in the certificate store on the machine when you run the Keyfactor Command installation. A hardware security module (HSM) may be used, if desired. To support the use of an HSM, the Windows CSP driver for the HSM must be installed on the Keyfactor Command server. Be aware that transactions accessing the encrypted data—such as enrolling for PFX certificates, downloading PFX certificates, running inventory, and adding certificates to certain types of certificate stores (e.g. F5, NetScaler)—will require accessing the HSM. A slow HSM will slow down these processes.

Note: In an environment where there are multiple copies of Keyfactor Command pointing to the same database, each server running a Keyfactor Command instance will need to have the same encryption certificate AND the corresponding private key.

Note: The thumbprint of the certificate used for application-level encryption is stored in the registry on the Keyfactor Command server(s)—rather than in the Keyfactor Command database—to provide a further level of separation from SQL.

Warning: If the certificate used for application-level encryption or the private key for this certificate are removed from the Keyfactor Command server while data in the database is encrypted with this certificate, access to this data will be lost. Take care to ensure that this certificate and its private key remain in place or that there are backups of both the certificate and private key (with any necessary password) that can be accessed in the event that the certificate needs to be restored.

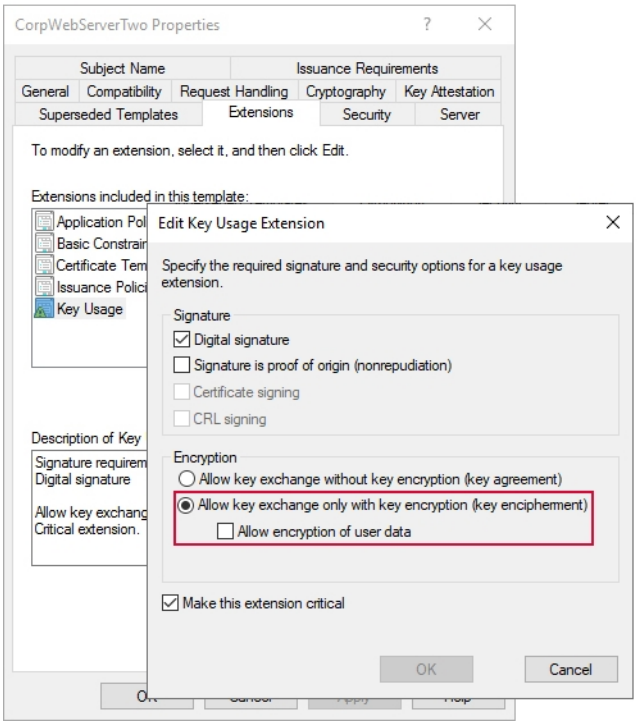

Figure 444: Certificate Template with Key Encipherment Key Usage

4.4.2.10 Grant Permissions in SQL

If you opt to use Windows authentication for the Keyfactor Command connection to SQL during the installation, the user who installs Keyfactor Command must have permissions to administer the SQL server and add databases and users (logins). To grant this, add the user who will install Keyfactor Command to the SQL server login list:

1. On the SQL server open the SQL Server Management Studio, connect to the database, and open **Security**.
2. Right-click on **Logins** and choose **New Login**.
3. Enter the domain name and user name of the administrative user who will be installing Keyfactor Command.
4. On the Login Properties page for this user, open Server Roles and check either the sysadmin role or the dbcreator, public and securityadmin roles. The full sysadmin permissions are needed if you're upgrading from a previous version of Keyfactor Command and the user running the install is not the same user who installed the previous version of Keyfactor Command.
5. Accept the remainder of the defaults and click **OK**.

If you opt to use SQL authentication, these permissions need to be granted to the SQL user.

Once Keyfactor Command has been deployed, the Windows user or SQL user used for the install can be removed from the Logins under Security in the SQL Server Management Studio. Ongoing connectivity to the database is maintained using accounts created specifically for the purpose during the installation.

Note: From Keyfactor Command version 9.0, service accounts will not be created with the db_owner role. Instead, a new keyfactor_db_role will be created and granted to the service accounts. This role has permission on each of the schemas (dbo, ssl, ssh, cms_agents, etc.) and permission on the encryption certificate.

4.4.2.11 Install IIS and .NET on the Keyfactor Command Server

Internet Information Services (IIS) and .NET 4.7.2 or greater must be installed on the Keyfactor Command server(s) prior to installation of the Keyfactor Command software.

IIS is a standard Windows role added through the Windows Server Manager tool and .NET is a standard Windows feature added through the Windows Server Manager tool. You may need to update to .NET 4.7.2 or greater with a downloadable update package or through Windows update.

Important: IIS needs to be configured to allow requests using the HTTP verbs DELETE, GET, POST and PUT to reach the Default Web Site (or other web site if you choose to install to an alternate web site). These are enabled by default. To check whether any of these have been disabled, open the IIS Management console, drill down to highlight the Default Web Site, double-click **Request Filtering** in the center pane, and review the information on the **HTTP Verbs** tab.

To verify the version of .NET installed, either:

1. Open the Registry Editor:

   ```
   regedit
   ```

2. Navigate to:

   ```
   HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\NET Framework Setup\NDP\v4\Full
   ```

3. Validate that the **Release** attribute value indicates a version of .NET Framework that is 4.7.2 or higher is installed, as shown in Table 761: .NET Framework Release Values.

Or:

1. Open a command prompt or PowerShell window and type the following command:

   ```
   reg query "HKLM\Software\Microsoft\NET Framework Setup\NDP\v4\Full"
   ```

2. Validate that the **Release** attribute value indicates a version of .NET Framework that is 4.7.2 or higher is installed, as shown in Table 761: .NET Framework Release Values.

Table 761: .NET Framework Release Values

.NET Framework	Release Value (Decimal)	Release Value (Hexadecimal)
.NET Framework 4.6.2	394802 or 394806	60632 or 60636
.NET Framework 4.7	460805	70805
.NET Framework 4.7.1	461308 or 461310	709FC or 709FE
.NET Framework 4.7.2	461808 or 461814	70BF0 or 70BF6
.NET Framework 4.8	528040, 528049, 528372, or 528449	8oEA8, 80EB1, 80FF4, 81041

Windows Server 2019 and 2022

The following figures show the components of IIS and .NET necessary to support Keyfactor Command on Windows Server 2019 and 2022. Your Keyfactor Command server may have additional roles or features installed that are not shown in these figures.

Important: Do not install the IIS *WebDAV Publishing* feature. Keyfactor Command will not operate correctly if this feature is installed.

Keyfactor Command makes use of the Active Directory tools for PowerShell to do group membership queries in Active Directory in some functions (e.g. when using a group to create a mapping between a Linux logon for SSH and one or more SSH keys). The *Active Directory module for Windows PowerShell* is installed as a feature as part of the *Remote Server Administrator Tools*.

Note that it is possible to install IIS and the necessary features using PowerShell rather than the below-referenced GUI-based installation method. The correct PowerShell command for this is:

```
Install-WindowsFeature Web-Server, Web-Asp-Net45, Web-Default-Doc, Web-Dir-Browsing, Web-Http-Errors,
Web-Static-Content, Web-Http-Logging, Web-Stat-Compression, Web-Filtering, Web-Basic-Auth, Web-
Windows-Auth, Web-Net-Ext45, Web-ISAPI-Ext, Web-ISAPI-Filter, Web-Mgmt-Console, RSAT-AD-PowerShell
```

Tip: To check and see if all the required roles and features have been installed, use Get-WindowsFeature with the same list of roles and features like so:

```
Get-WindowsFeature Web-Server, Web-Asp-Net45, Web-Default-Doc, Web-Dir-Browsing, Web-Http-
Errors, Web-Static-Content, Web-Http-Logging, Web-Stat-Compression, Web-Filtering, Web-Basic-
Auth, Web-Windows-Auth, Web-Net-Ext45, Web-ISAPI-Ext, Web-ISAPI-Filter, Web-Mgmt-Console,
RSAT-AD-PowerShell
```

Output from this command will look something like the following, which shows some required features installed and some missing. Make sure all roles and features in the query output are marked *Installed* before continuing.

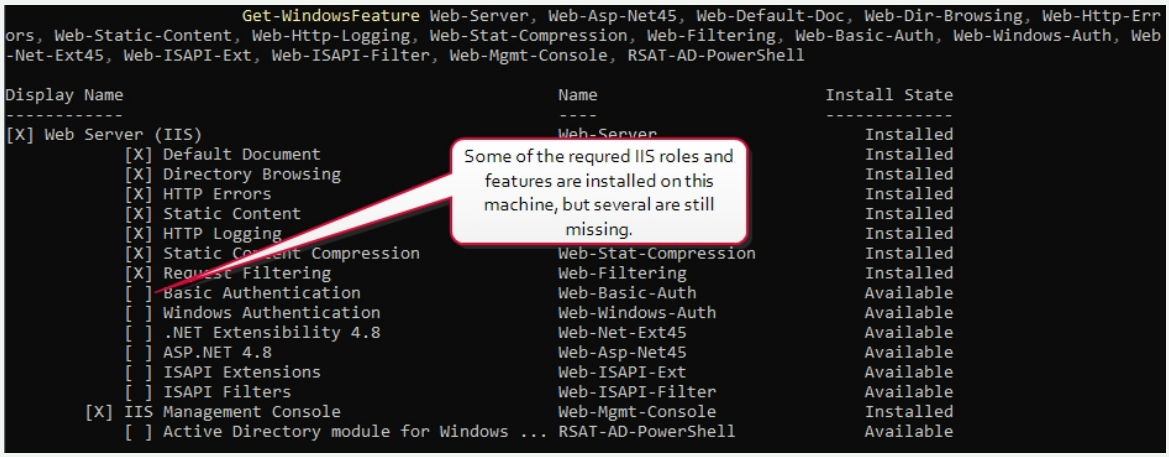

Figure 445: Use Get-WindowsFeature to Determine if All Required Roles and Features are Installed

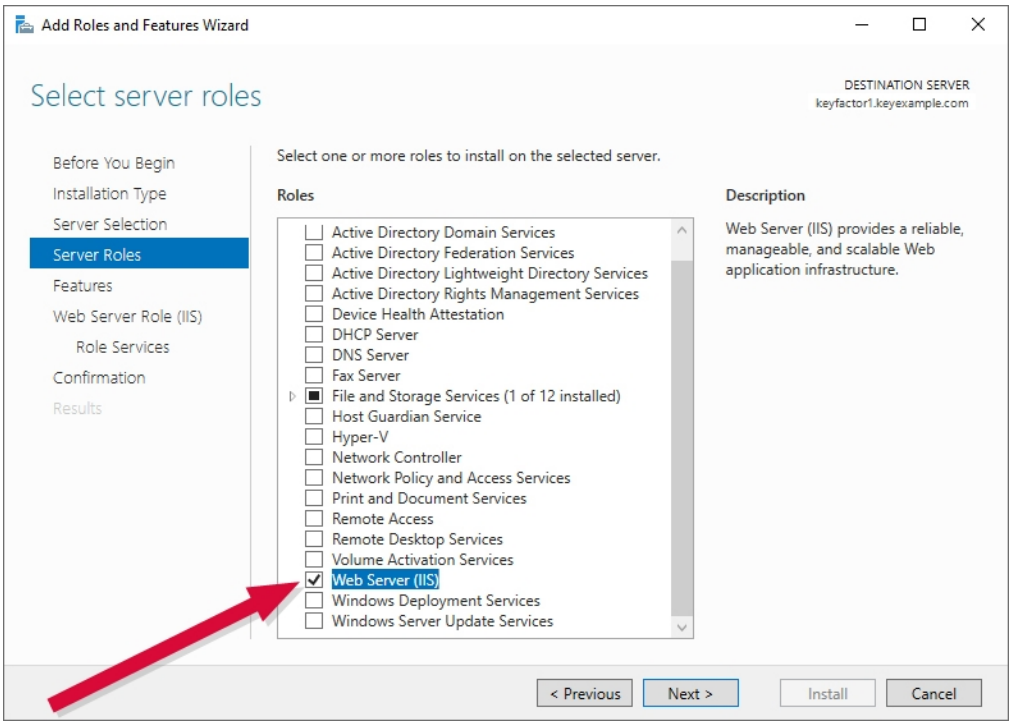

Figure 446: Web Server Role

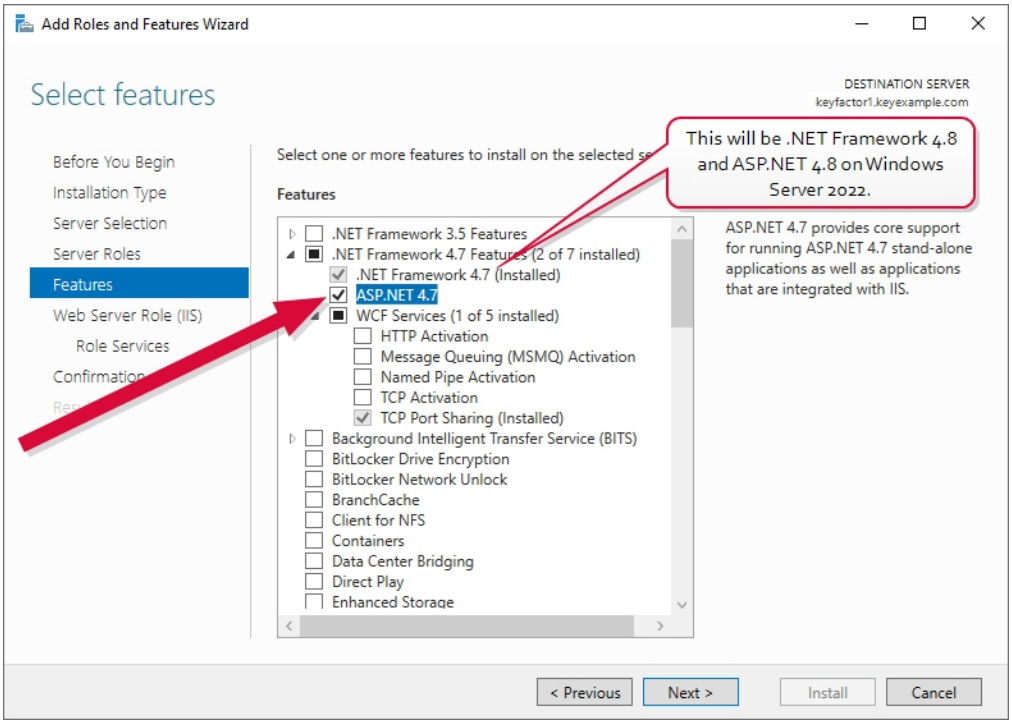

Figure 447: .NET 4.7 Feature

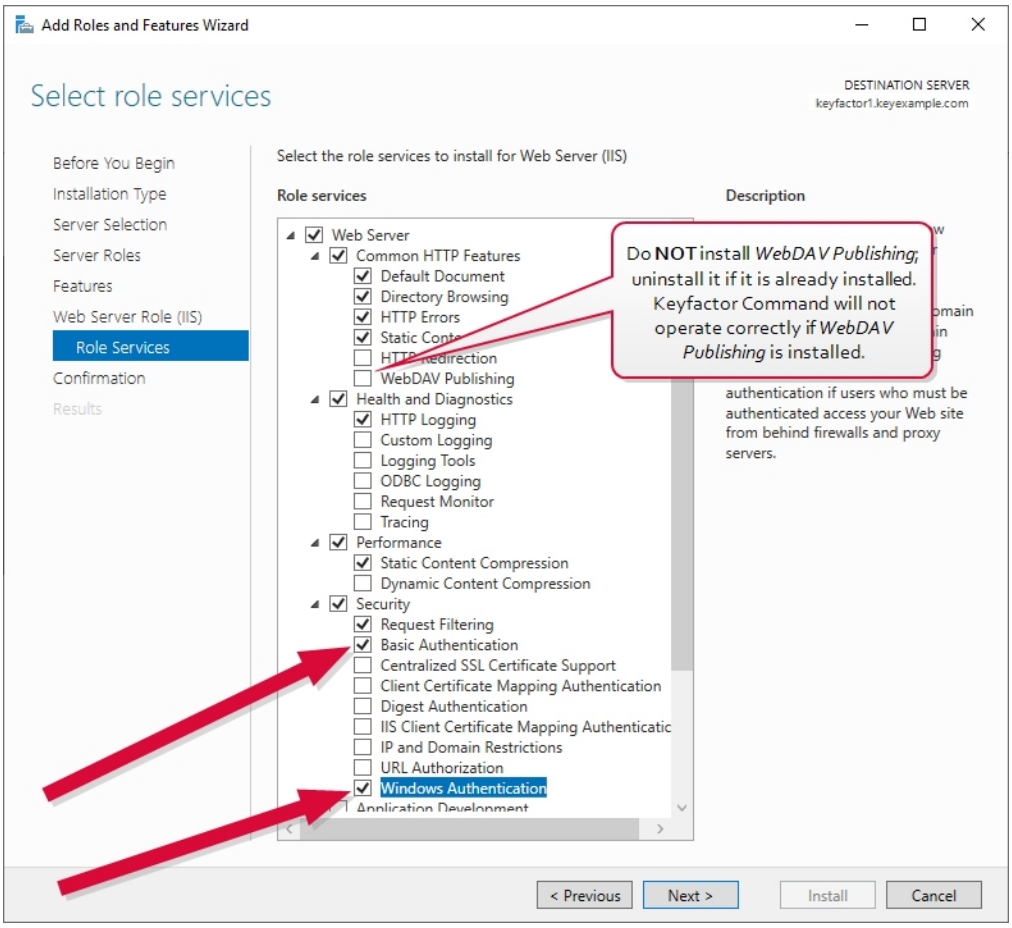

Figure 448: Role Services Page One

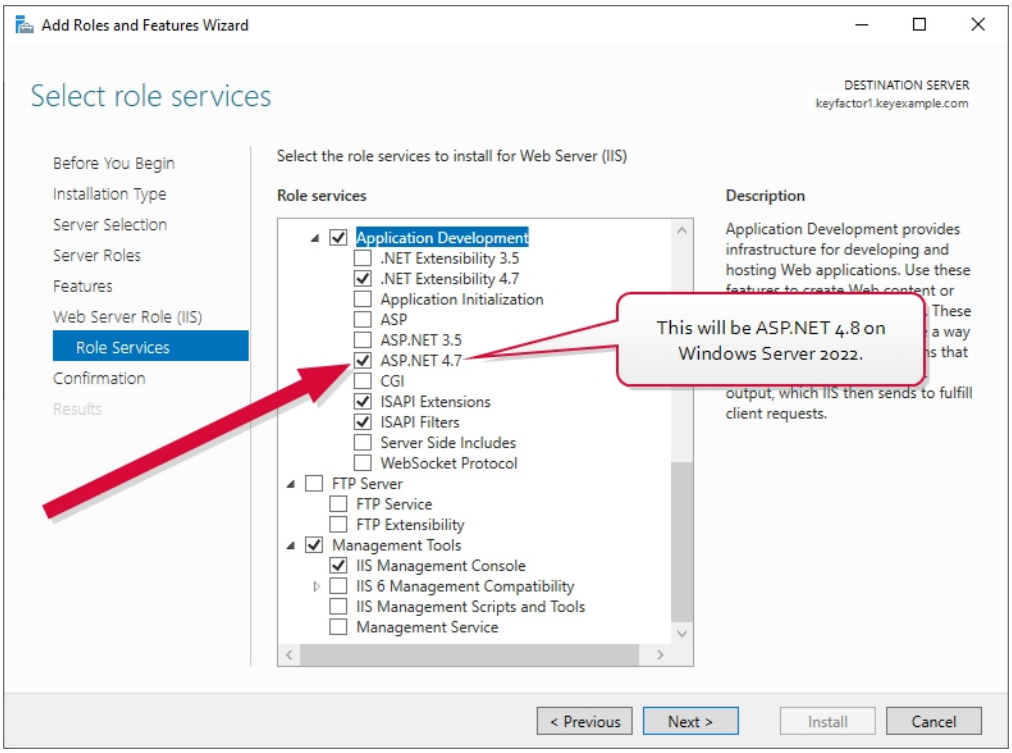

Figure 449: Role Services Page Two

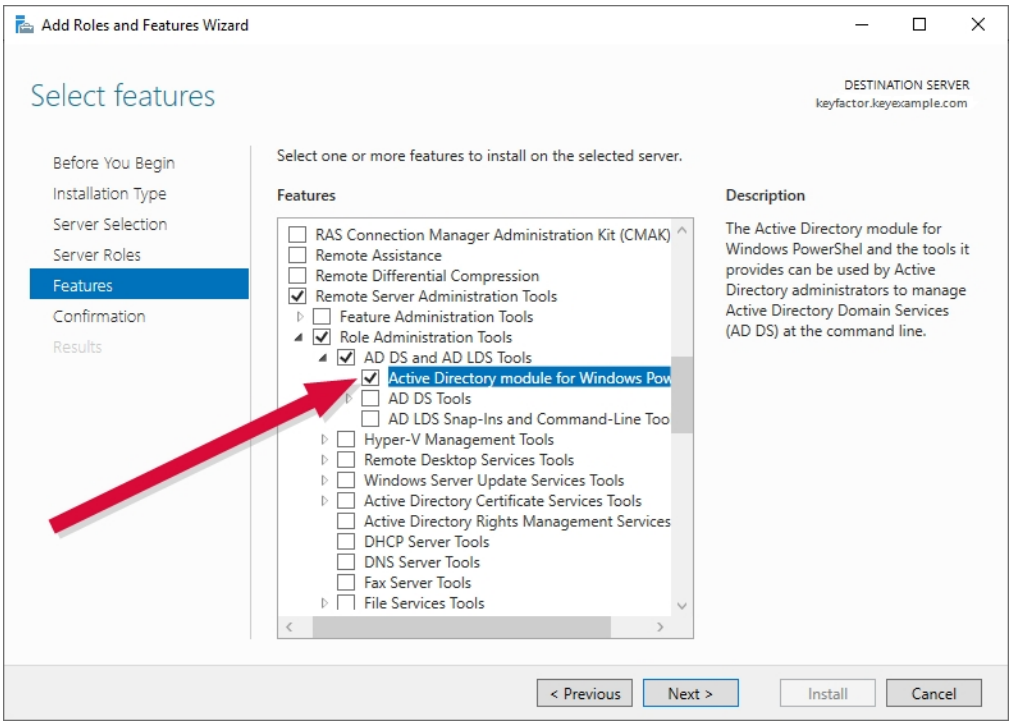

Figure 450: Active Directory Module for Windows PowerShell

4.4.2.12 Configure SSL for the Default Web Site on the Keyfactor Command Server

Once you have acquired an SSL certificate for Keyfactor Command and installed IIS, you can open the IIS Management Console and associate the certificate with the Default Web Site. You can do this either before or after installing Keyfactor Command.

To import your SSL certificate and associate it with the Default Web Site:

1. Open the IIS Manager MMC snap-in.
2. Navigate to the connection for the current host. (The top level in IIS.)
3. On the current host Home page, open (double-click) Server Certificates. If your SSL certificate already appears in this list, you can skip steps 4-7.
4. On the Server Certificates page, select Import… under Actions.
5. In the Certificate file (.pfx) field, choose the browse option and navigate to the .pfx or .p12 file containing your certificate.
6. Enter the password for your certificate, select the Personal Certificate Store, check the Allow this certificate to be exported box if desired, and click **OK**.
7. Your certificate should now appear in the list of Server Certificates. Confirm that the Issued To column shows your certificate name correctly (e.g. keyfactor.domain.com).
8. Navigate to the Default Web Site and on the Default Web Site Home page, select Bindings… under Actions.
9. In the Site Bindings dialog, highlight the https entry if it exists and choose Edit. If an https entry does not exist, click **Add**.
10. In the Edit Site Bindings dialog, select https in the Type dropdown (this will already be selected and grayed out if you selected Edit in the previous step), select the certificate you just imported in the SSL certificate drop-down box, and click **OK**.

Note that these instructions assume that your SSL certificate has been provided in PKCS12 format file. If you are requesting a certificate directly from an on-premise CA through IIS or are generating a CSR through this IIS installation to submit to a CA, the configuration steps will be different.

4.4.2.13 Configure the Keyfactor Command Server to Require SSL

For best security practice, the Keyfactor Command web site should be configured to require SSL for all access. To do this:

1. Open the IIS Manager MMC snap-in.
2. Navigate to the Default Web Site.
3. Under the Default Web Site Home, select **SSL Settings**.
4. On the SSL Settings page, check the **Require SSL** box and, under Actions, click **Apply**.

Important: The Keyfactor Command web application is not configured to support HTTP Strict Transport Security (HSTS) by default. HSTS is a web security policy mechanism that helps to protect websites against protocol downgrade attacks and cookie hijacking. An application enables HSTS by returning an HTTP response header that instructs users' browsers to only interact with the site using secure transport methods. HSTS is supported by all modern browsers. To accommodate this, configure the server to always send the "Strict-Transport-Security" HTTP header on HTTPS connections:

```
Strict-Transport-Security: max-age=31536000; includeSubDomains
```

The max-age parameter is given in seconds; the value shown above is equivalent to one year.

Instructions for implementation of HSTS are beyond the scope of this guide.

4.4.2.14 Prepare for External Log Shipping over TLS (Optional)

Keyfactor Command offers the option to copy audit logs in real time to a separate server for collection and analysis with a centralized logging solution (e.g. rsyslog, Splunk, Elastic Stack). This can be done either over standard UDP/TCP connections, or you can opt to secure the connection to the backend log collection solution using TLS. This requires a backend solution that supports receiving logs over TLS and, typically, a client certificate on the Keyfactor Command server and a server certificate on the backend server.

The following instructions cover using rsyslog on the backend and will differ if you are using an alternative log collection solution.

Acquire the client certificate(s) using the Fully Qualified Domain Name (FQDN) of the server or alias used for the Keyfactor Command server(s) (see Hostname Identification and Resolution on page 2235). For example:

```
keyfactor.keyexample.com
```

The certificate must be installed on the Keyfactor Command server(s) prior to installation of the Keyfactor Command software.

To acquire a client certificate for use in log shipping using a Microsoft CA, first create or identify a template that has an extended key usage (EKU) of *Client Authentication* and make it available for enrollment on a CA to which the Keyfactor Command server has access with enrollment permissions for the Keyfactor Command server. If desired, you can use a template that has both the *Client Authentication* and *Server Authentication* EKUs and use it for certificates on both sides of the communication. Start by copying a computer template if you want to enroll for the certificate using the Microsoft MMC as described below and without needing to set the private key of the certificate as exportable.

To enroll for a client certificate using the MMC:

1. On the Keyfactor Command server, do one of following:
    - Using the GUI:
        a. Open an empty instance of the Microsoft Management Console (MMC).
        b. Choose **File->Add/Remove Snap-in…**.
        c. In the *Available snap-ins* column, highlight **Certificates** and click **Add**.
        d. In the Certificates snap-in popup, choose the radio button for Computer account, click **Next**, accept the default of Local computer, and click **Finish**.
        e. Click **OK** to close the Add or Remove Snap-ins dialog.
    - Using the command line:
        a. Open a command prompt using the "Run as administrator" option.
        b. Within the command prompt type the following to open the certificates MMC:
        certlm.msc
2. Drill down to the Personal folder under **Certificates** for the Local Computer, right-click, and choose **All Tasks->Request New Certificate…**.
3. Follow the certificate enrollment wizard, selecting the template you created or identified for use for this purpose, and providing any required information, being sure to set the CN to the FQDN of the Keyfactor Command server.

Tip: If you have an existing Keyfactor Command and wish to enroll through Keyfactor Command, you can request the certificate using the PFX enrollment option and either push it out to the Keyfactor Command local machine store using an IIS personal certificate store managed with a Keyfactor Universal Orchestrator installed on Windows or Keyfactor Windows Orchestrator or import it to the certificate store using the PFX generated from Keyfactor Command and one of these orchestrators.

Note: The Keyfactor Command needs to be configured to trust the CA that issued the certificate to the rsyslog server. If you have opted to acquire certificates from a CA for which a root trust is not already configured on the Keyfactor Command server, this will need to be configured.

To acquire a server certificate for use in log shipping using a Microsoft CA, first create or identify a template that has an extended key usage (EKU) of *Server Authentication* and make it available for enrollment on a CA to which the server from which you are requesting the certificate has access with enrollment permissions for the server from which you are requesting the certificate.

To enroll for a server certificate using the MMC:

1. On a Windows server with appropriate enrollment access, do one of following:
    - Using the GUI:
        a. Open an empty instance of the Microsoft Management Console (MMC).
        b. Choose **File->Add/Remove Snap-in…**.
        c. In the *Available snap-ins* column, highlight **Certificates** and click **Add**.
        d. In the Certificates snap-in popup, choose the radio button for Computer account, click **Next**, accept the default of Local computer, and click **Finish**.
        e. Click **OK** to close the Add or Remove Snap-ins dialog.
    - Using the command line:
        a. Open a command prompt using the "Run as administrator" option.
        b. Within the command prompt type the following to open the certificates MMC:
            certlm.msc
2. Drill down to Certificates in the Personal folder under **Certificates** for the Local Computer and locate your newly created certificate. Right-click on the certificate and choose **All Tasks->Export…**.
3. Follow the certificate export wizard, being sure to answer **Yes, export the private key** and choosing the option to **Include all certificates in the certificate path if possible**. Set a password to secure the exported private key.
4. In the MMC, drill down to the Personal folder under **Certificates** for the Local Computer, right-click, and choose **All Tasks->Request New Certificate…**.
5. Securely copy the resulting PFX file to your rsyslog server and place it in a temporary working directory.
6. Use openssl to break the PFX file apart into separate certificate and key files and remove the encryption on the key file (rsyslog does not provide a method for providing the password necessary to use the encrypted file) as follows:
    a. Execute the following command to pull the key out of the PFX file (provide the input password for the PFX when prompted and the output password for the PEM key file when prompted):
        ```
        openssl pkcs12 -in mycertfile.pfx -nocerts -out mykey.pem
        ```
    b. Execute the following command to pull the certificate out of the PFX file (provide the input password for the PFX when prompted):
        ```
        openssl pkcs12 -in mycertfile.pfx -clcerts -nokeys -out mycert.pem
        ```
    c. Execute the following command to pull the chain certificate(s) out of the PFX file (provide the input password for the PFX when prompted):
        ```
        openssl pkcs12 -in mycertfile.pfx -cacerts -nokeys -chain -out cacerts.pem
        ```
    d. Execute the following command to remove the encryption from the key so that a password will not be required when accessing the key file (provide the PEM key password you set in the first step):
        ```
        openssl rsa -in mykey.pem -out mynewkey.key
        ```

7. Identify a secure location on the rsyslog server to store the certificates and key file (e.g. /etc/tls/certs and /etc/tls/private) and copy the certificates and key to these locations, setting appropriately secure permissions on the files. The key needs to be readable by the rsyslog daemon.

Tip: If you have an existing Keyfactor Command and wish to enroll through Keyfactor Command, you can request the certificate using the PFX enrollment option, opt to download it as a ZIP PEM, copy the zip file to the rsyslog server, unzip, and distribute the files as described in the final step, above.

Configuration of rsyslog for TLS support may vary depending on your needs. In addition to the standard rsyslog package for your Linux server, you will need GNU TLS packages to support TLS communication. For example, for Ubuntu the required packages are:

```
rsyslog
rsyslog-gnutls
gnutls-bin
```

The following is an example rsyslog.conf file configured for TLS support:

```
# /etc/rsyslog.conf configuration file for rsyslog
#
# For more information install rsyslog-doc and see
# /usr/share/doc/rsyslog-doc/html/configuration/index.html
#
# Default logging rules can be found in /etc/rsyslog.d/50-default.conf

A filter similar to the following can be used to redirect all Keyfactor Command related traffic to a particular file:

```
:syslogtag, isequal, "Keyfactor" /var/log/keyfactor/audit.log
```

4.4.3 Installing

The following installation instructions cover installing all Keyfactor Command server components on a single server performing all Keyfactor Command roles. You may choose to separate the roles onto different servers. If you do, the installation process will vary from the described process.

4.4.3.1 Install the Main Keyfactor Command Components on the Keyfactor Command Server(s)

The following installation steps show all possible Keyfactor Command features enabled. Your Keyfactor Command license may not cover all Keyfactor Command features. If it does not, unlicensed features will not be shown in the configuration wizard. You may skip those configuration steps.

To begin the Keyfactor Command installation, execute the KeyfactorPlatform.msi file from the Keyfactor Command installation media and install as follows.

1. On the first installation page, click **Next** to begin the setup wizard.

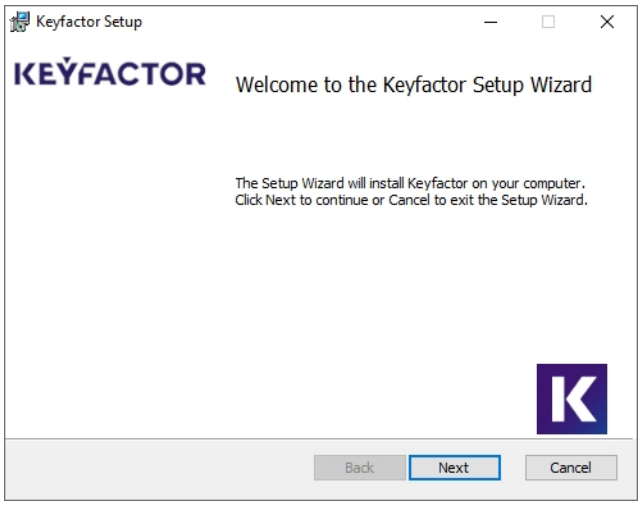

Figure 451: Install: Begin Setup Wizard

2. On the next page, read and accept the license agreement and click **Next**.

3. On the next page, select the components to install. For a server with the default roles collocated, leave the default options and click **Next** to continue. The vSCEP Validation Service component is not selected by default. If desired, you can highlight Keyfactor Command and click **Browse** to select an alternate installation location for the files. The default installation location is:

    ```
    C:\Program Files\Keyfactor\Keyfactor Platform\
    ```

    Note: Although Figure 452: Install: Select Components shows only the default components selected, the remainder of this page covers configuring Keyfactor Command as though all the components have been selected.

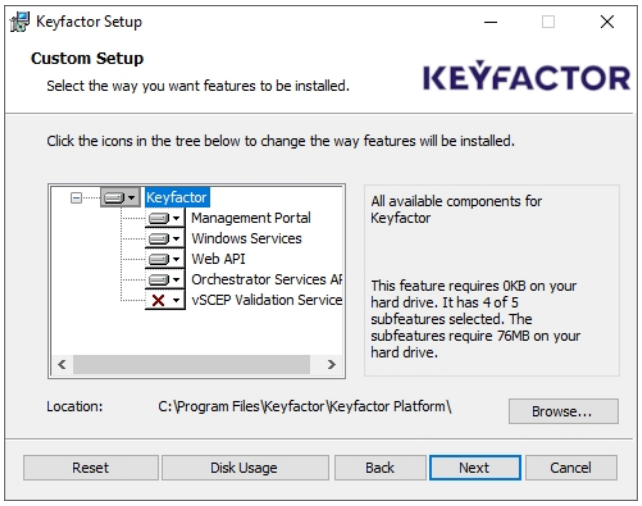

Figure 452: Install: Select Components

Tip: Refer to Keyfactor Command Server(s) on page 2227 for information about configuring the roles for these components.

Table 762: Available components for Keyfactor.

Component	Description
Management Portal	**Mandatory**. Web-based management console for configuring all aspect of Keyfactor. The new API will be installed with this component.
Windows Services	**Mandatory**. Includes the timer Windows service to manage timed events, such as CA Sync, PKI monitoring and system maintenance.
Web API	Optional. The API component. Disabling Web API will remove the classic API from being installed. Enabling it will install both the classic and new API.
Orchestrator Services	Optional. Not required if neither agents nor orchestrators will be utilized by Keyfactor Command. Web based orchestrator services API.
vSCEP	Optional. vSCEP services used to validate certificate requests

4. On the next screen, click **Install**.
5. On the final installation wizard page, leave the "Launch the Configuration Wizard now" box selected and click **Finish**. The configuration wizard should start automatically. This can take several seconds.
6. On the Keyfactor Command Database Configuration page, enter the name, IP address, or fully qualified domain name (FQDN) of your SQL server and select a Credential Type of either **Windows** or **SQL**.

Important: Keyfactor Command uses an encrypted channel to connect to the SQL server by default, which requires configuration of an SSL certificate on the SQL server (see Using SSL to Connect to SQL Server on page 2222). The name or IP address you enter here for your SQL server must be available as a SAN in this certificate unless you have disabled the encrypted connection for Keyfactor Command (see Configurable SQL Connection Strings on page 2226).

- If you select **Windows** as the Credential Type for connecting to SQL, click the **Connect** button.

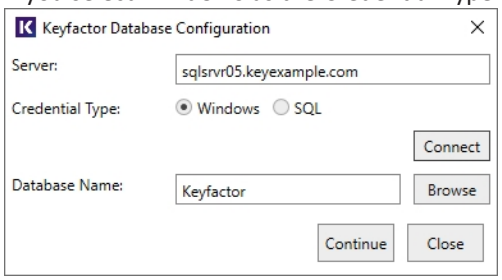

Figure 453: Windows Authentication

- If you select **SQL** as the Credential Type for connecting to SQL, the window will expand to include fields to enter a SQL username and password. Enter a username and password to authenticate to SQL, and click the **Connect** button.

  Note: The password must not contain single or double quotes. An error will be shown if single or double quotes are used in the password. For the permissions required for this user, see Grant Permissions in SQL on page 2241.

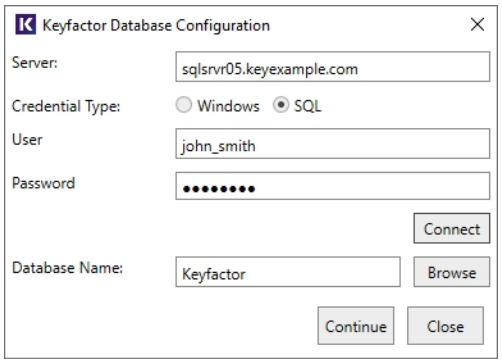

Figure 454: SQL Authentication

Note: Keyfactor Command supports configuration of a base SQL connection template that is used for all connections Keyfactor Command makes to SQL. For more information, see Configurable SQL Connection Strings on page 2226.

Note: Keyfactor recommends that you accept the default Credential Type of Windows unless you have a strong need to do otherwise. Your SQL server must be configured to support mixed mode authentication in order to use the SQL option.

7. After the **Connect** button is clicked, the database name field will be activated. You can either enter the name of the desired database—for either a new or existing database—or click **Browse** to scroll through a list of existing databases.

   Note: On subsequent runs of the configuration wizard, the database name field will be pre-populated with the database name used on the last completed run. Any change to the server connection fields (server name, authentication type, etc.) will require the Connect button to be used again to unlock the database name field and the Continue button.

8. Click the **Continue** button. You will receive a confirmation dialog if any changes will be made to the database at this stage.

   Note: If any of the following situations occurs, you will receive a message:

   - The selected database does not exist and will be created.
   - The selected database is empty and not associated with Keyfactor Command; it will be populated with the Keyfactor Command schema.
   - The selected database does not match the current product schema and will be upgraded.
   - The selected database is not empty and is not associated with Keyfactor Command.
   - The user does not have access to the database.
   - An SSL certificate is not correctly configured on the SQL server.

9. On the Keyfactor Command Encryption Warning page, read and understand the warning. Make note of the referenced documents to provide to your SQL team. Take advantage of the option to make a backup of the Database Master Key (DMK) by entering a path to a directory on your SQL server along with a filename for the backup file and a password to encrypt the file and clicking **Backup**. The user running the Keyfactor Command installer must have write permissions to this directory. Click **Continue**.

   Important: Keyfactor Command uses Microsoft SQL Server encryption to protect security sensitive data, including service account credentials. Backup of the SQL server Database Master Key (DMK) is of critical importance in database backup and recovery operations. The backup file of the DMK and the password should be stored in a safe, well-documented location. Without the file and password created with this process, some data that is encrypted within the Keyfactor Command database will be unrecoverable in a disaster recovery scenario. For more information, see SQL Encryption Key Backup on page 666 in the *Keyfactor Command Reference Guide*.

   If you choose to install Keyfactor Command in the default location, the referenced documents can later be found here:

```
C:\Program Files\Keyfactor\Keyfactor Platform\Configuration\DMKBackup.docx
C:\Program Files\Keyfactor\Keyfactor Platform\Configuration\DMKRestore.docx
```

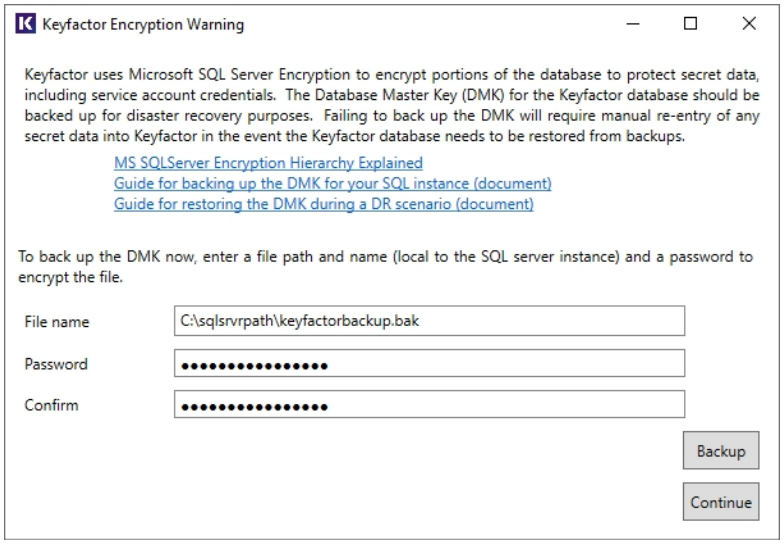

Figure 455: Configure: Backup Database Master Key

10. On the Keyfactor Command License upload page, click **Upload** and browse to locate the license file provided to you by Keyfactor. This file should have the extension CMSLICENSE. Once the uploaded license shows as valid, click **Continue**.

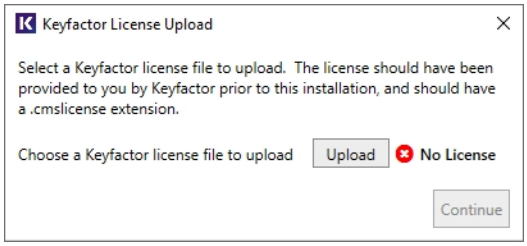

Figure 456: Configure: Upload License

11. In the Keyfactor Command configuration wizard, you can choose to upload a configuration file to populate the fields. You may have a file saved from a previous run of the configuration wizard or you may be provided one by Keyfactor. To upload a file, in the configuration wizard, click **File** at the top of the wizard and choose Open Data File… . Browse to locate the configuration file. Configuration files have an extension of .cmscfg. The file may be protected with a password. If it is, you will need to provide this password to open the file. Continue with the remainder of the steps, reviewing the tabs to assure that the data is complete and correct.

> **Note:** At the bottom of the configuration wizard, if the database server name is longer than will fit in the provided window, it will be truncated and an ellipsis will be added.

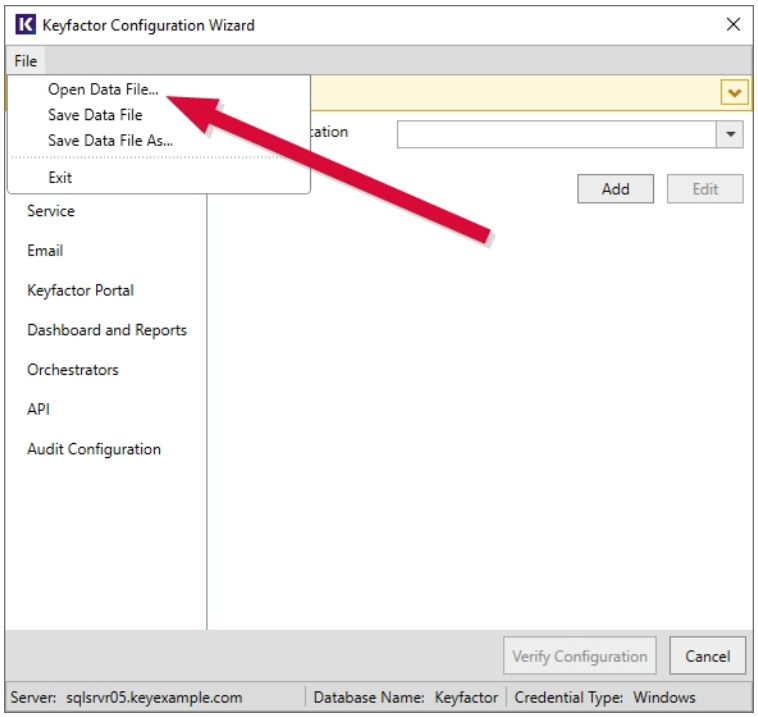

Figure 457: Configure: Open Data File

12. Application Pools Tab

    On the Application Pools tab of the configuration wizard, click **Add**, change the default application pool name, if desired, and enter the user name (DOMAIN\username format) and password of the Active Directory service account under which the application pool will run. You may use the people picker button ( ) to browse for the account. Click the verify button ( ) to confirm that the username and password entered are valid. Assuming the verification completes successfully, click **Save**.

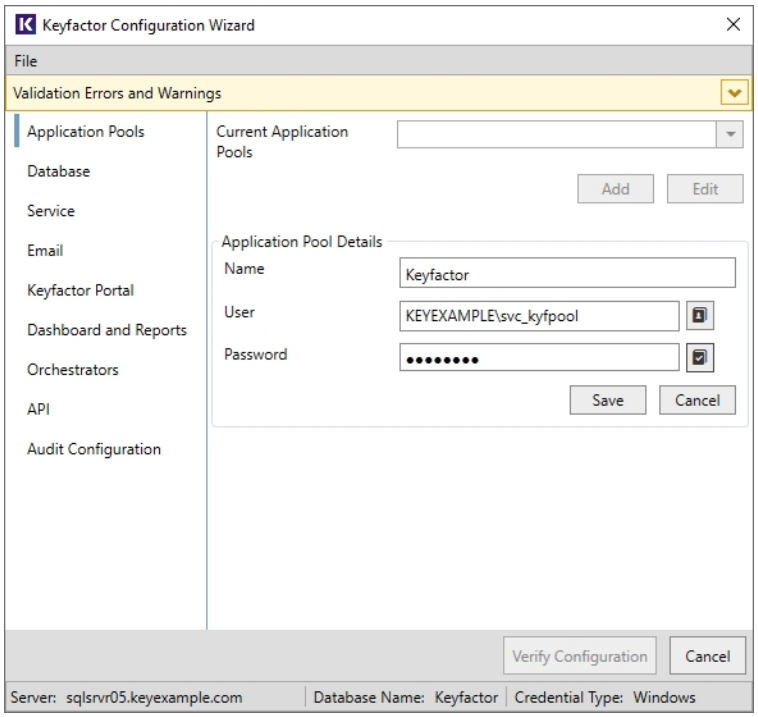

Figure 458: Configure: Application Pools

13. Database Tab

    On the Database tab in the top section, select an Authentication Mode for ongoing communications to SQL server—**Windows Authentication** or **SQL Server Authentications**. Your SQL server must be configured to support mixed mode authentication in order to use the SQL server authentication option. If you choose SQL server authentication, enter the Username and Password for a SQL administrator for the Keyfactor Command SQL database. If the user does not exist in SQL, it will be created and granted the necessary permissions for management of the Keyfactor Command database (db_owner). If the user already exists in SQL, it will be granted the necessary permissions. If the database you originally connected to is an Azure database, **SQL Server Authentication** is the only option provided.

    If desired, check the **Configure Encryption** box. This option allows you to encrypt select sensitive data stored in the Keyfactor Command database using a separate encryption methodology utilizing a Keyfactor Command-defined certificate on top of the SQL server encryption noted above. This additional layer of encryption protects the data in cases where the SQL Server master keys cannot be adequately protected. Read and understand the encryption warning. This warning applies to implementations with more than one Keyfactor Command server.

    Note: In an environment where there are multiple copies of Keyfactor Command pointing to the same database, each server running a Keyfactor Command instance will need to have the same encryption certificate AND the corresponding private key.

Select **Application and SQL** for the **Encryption Type** and click the **Select** button to choose a certificate from the Personal Certificate store of the Local Computer with which to encrypt the data. Only valid certificates with the appropriate key usage will appear in the selection dialog. See Acquire a Public Key Certificate for the Keyfactor Command Server on page 2239.

Tip: If you need to reset the encryption level to remove application-level encryption, run the configuration wizard again and select the **SQL Only** option. You must ensure that the server you are re-running the configuration wizard on has both the certificate used for application-level encryption and its associated private key. When Keyfactor Command notices that application-level encryption has been disabled, it will process all the secrets in the database and remove the additional encryption. The data will then be re-saved to the secrets table using only SQL-level encryption.

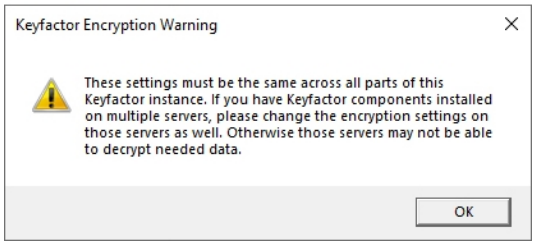

Figure 459: Configure: Encryption Warning

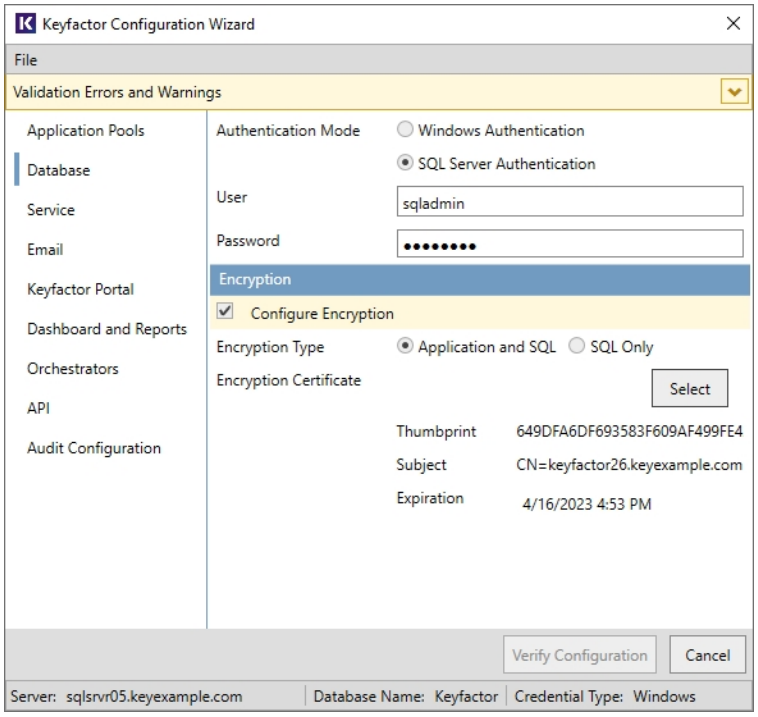

Figure 460: Configure: Database

14. Service Tab

    On the Service tab, enter the user name (DOMAIN\username format) and password of the Active Directory service account under which the Keyfactor Command Service will run. This can be the same service account used for the application pool or a different service account. You may use the people picker button () to browse for the account. Click the verify button () to confirm that the username and password entered are valid. If desired, check the **Start service on bootup** box to start the Keyfactor Command Service at system start.

    The remaining fields on this tab are used to configure the jobs that the Keyfactor Command Service will run. If you're installing a single Keyfactor Command server, you should enable all jobs for this server by checking the **Everything** box unless you are specifically aware of a job that doesn't need to be run. For example, if you've opted not to use the SSL scanning functionality, you can uncheck **Everything** and then uncheck the **Endpoint History Purge** box. Services details are shown in Table 763: Keyfactor Command Services. At the bottom of the list of services, modify the default value of 1000 for **Concurrent Workflows**, if desired.

    If you are installing multiple Keyfactor Command servers in a redundant solution, Keyfactor recommends checking the **Everything** box to run all the service jobs on all Keyfactor Command servers. This allows the Keyfactor Command Service to manage the jobs most efficiently. However, you do have the option to configure different service jobs on your different Keyfactor Command nodes (so server 1 might run Maintenance jobs, while server 2 runs Certificate Authority jobs, etc.). To do this, uncheck the **Everything** box and check the boxes next to the services that should run on a particular Keyfactor Command server instance.

Table 763: Keyfactor Command Services

Type	Service	Description	Notes
Maintenance	Synchronization	Periodically synchronize certificates from certificate authorities.	The schedules for this are user configurable (see Certificate Authorities on page 307 in the *Keyfactor Command Reference Guide*).
Maintenance	Bulk Audit Entry Processing	Periodically add audit log entries for large jobs. Most audit log entries are added immediately at the time the activity generating the audit log takes place. However, some large jobs that might generate heavy server load (e.g. bulk revocation) save the audit log entries in a temporary location to reduce server load and then they are added to the audit log by this periodic job.	This job runs every 10 minutes.
Maintenance	Metadata Generation	Periodically generate and assign metadata to certificates when they are imported into Keyfactor Command using a custom metadata extension.	This job runs every 15 minutes.
Maintenance	Private Key Cleanup	Periodically remove any stored private keys in the Keyfactor Command database that have expired and are eligible for deletion.	This job runs daily at 1:00 am. For more information about stored private keys, see Status Tab on page 20 in the *Keyfactor Command Reference Guide*.
Maintenance	Purge Audit Log History	Periodically remove any audit log history in the Keyfactor Command database that has expired and is eligible for deletion.	This job runs monthly on the first day of the month at 2:00 am. For more information, see Application Settings: Auditing Tab on page 559 in the *Keyfactor Command Reference Guide*.

Type	Service	Description	Notes
			Only audit logs belonging to unprotected categories are eligible for deletion.
Maintenance	Endpoint History Purge	Periodically remove any SSL endpoint history in the Keyfactor Command database that is eligible for deletion, based on the setting in Application Settings: Auditing Tab on page 559(*SSL > Retain SSL Endpoint History (days)*) in the *Keyfactor Command Reference Guide*.	This job runs daily at 1:00 am.
Maintenance	Report Cleanup	Periodically remove records from temporary files generated while running reports.	This job runs daily at midnight.
Maintenance	Update Stats	Periodically run the Microsoft SQL update statistics function in the Keyfactor Command database.	This job runs monthly on the first day of the month at 1:00 am.
Maintenance	Sync Templates	Periodically synchronize certificate templates from the source (e.g. Active Directory) to pick up new templates.	This job runs every hour.
Maintenance	Schedule SSL Jobs	Periodically identify and schedule SSL discovery and monitoring jobs.	This job runs every 5 minutes.
Maintenance	Workflow Cleanup	Periodically remove any completed workflow instances (both successful and failed) in the Keyfactor Command database that have aged X number of days past the completion date (last modified date), where X is defined by the *Workflow Instance Cleanup Days* application setting (see Application Settings: Console Tab on page 554 in the *Keyfactor Command Reference Guide*). The default value is 14 days.	This job runs daily at midnight.
Alerts	CA Health	Periodically send email alerts when a CA is not responding.	The schedule for this is user configurable (see Certificate Authority Monitoring on page 332

Type	Service	Description	Notes
			in the *Keyfactor Command Reference Guide*).
Alerts	CA Threshold	Periodically send email alerts when a CA is issuing certificates or experiencing issuance failures outside of the established norms.	The schedule for this is user configurable (see Advanced Tab on page 321 in the *Keyfactor Command Reference Guide*).
Alerts	CRL	Periodically send email alerts for certificate revocation lists (CRLs) that are approaching expiration.	The schedule for this is user configurable (see Adding or Modifying a Revocation Monitoring Location on page 188 in the *Keyfactor Command Reference Guide*).
Alerts	Pending/Expiration	Periodically send email alerts (typically to certificate approvers) for certificate requests made using a certificate template that requires manager approval. Periodically send email alerts for certificates approaching expiration.	The schedules for these are user configurable. See Configuring a Pending Request Alert Schedule on page 165 and Configuring an Expiration Alert Schedule on page 155 in the *Keyfactor Command Reference Guide*.
Alerts	Collection Membership Caching	Periodically update the temporary tables that store information on which certificates are in which certificate collections. These temporary tables (caches) are used to support faster processing of some systems.	This value is user configurable with an application setting (see Application Settings: Console Tab on page 554 in the *Keyfactor Command Reference Guide*). The default is 20 minutes.
Alerts	Issued Alerts	Periodically send email alerts (typically to certificate requesters) for certificate requests made using a certificate	The schedule for this is user configurable (see

Type	Service	Description	Notes
		template that requires manager approval that have been approved.	Configuring an Issued Request Alert Schedule on page 173 in the *Keyfactor Command Reference Guide*). A scheduled alert is only needed to deliver notifications for approvals done outside of Keyfactor Command.
Alerts	SSH Key Rotation Alerts	Periodically send email notifications to SSH key users and/or administrators when a key is nearing the end of the key lifetime.	The schedule for this is user configurable (see Configuring a Key Rotation Alert Schedule on page 184 in the *Keyfactor Command Reference Guide*).
Other	Reporting	Deliver regularly scheduled reports via email or saved to a file system.	The schedules for these are user configurable (see Reports on page 80 in the *Keyfactor Command Reference Guide*).
Other	Run Suspended Workflows	Periodically attempt to continue all suspended workflows that may be eligible to continue but have not done so due to locking conflicts. A locking conflict may occur if two users attempt to provide input to a workflow instance (e.g. approve a request) at exactly the same time.	This job runs daily at midnight.
n/a	Concurrent Workflows	Sets the batch size used when suspended workflows are run by the Keyfactor Command service.	The default value is 1000.

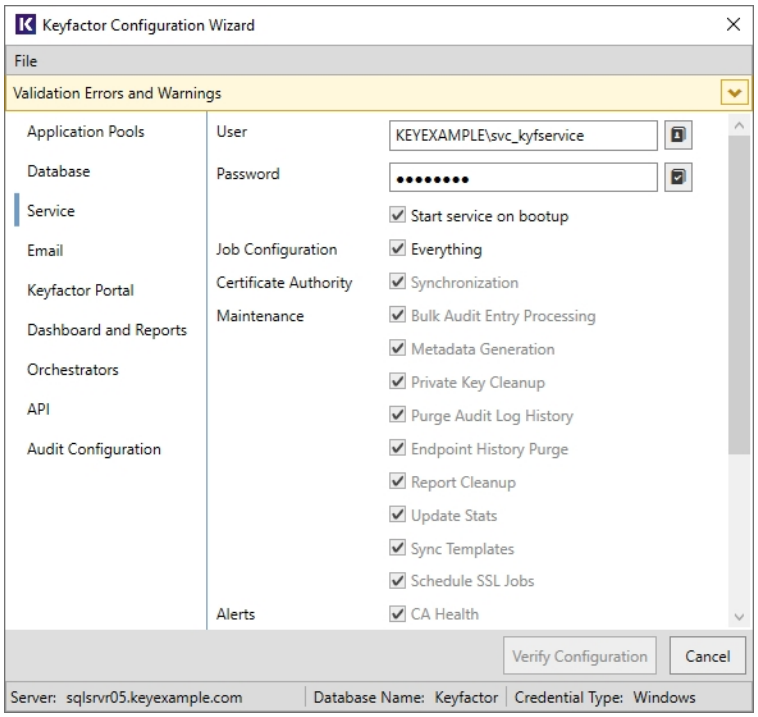

Figure 461: Configure: Service

15. Email Tab

    On the Email tab, enter the FQDN of your SMTP server, the SMTP port (default is 25), and the sender name and account. Depending on the email configuration in your environment, the sender account may need to be a valid user on your mail server (using Active Directory credentials) or you may be able to put anything in this field (if your mail server supports anonymous connections). You may use the people picker button ( ) to browse for the sender account if you are using a valid account. Select the **Use SSL** box if this option is supported by your mail server and select the appropriate authentication method for your environment. If your mail server requires that you provide a username and password for a valid user, enter that Active Directory username and password in the fields at the bottom of the page after selecting the **Explicit credentials** radio button. You may use the people picker button ( ) to browse for the account. Click the verify button ( ) to confirm that the username and password entered are valid. The user you select here must match the email address you set in the *Sender Account* field if you select *Explicit credentials*. The information entered on this tab may later be changed in the Keyfactor Command Management Portal.

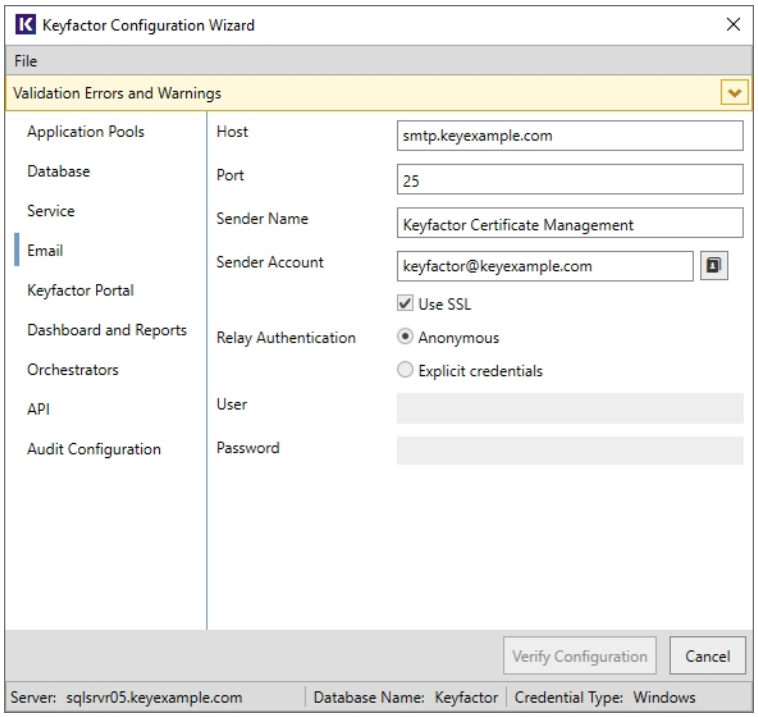

Figure 462: Configure: Email

16. Keyfactor Portal Tab

    On the Keyfactor Portal tab in the top section, enter the FQDN that you will use to access the Keyfactor Command Management Portal in the **Host Name** field. This can be either the actual host name of the server on which you are installing the Keyfactor Command Administration component or a DNS alias pointing to the server. If you have multiple Keyfactor Command Management Portal servers with load balancing, this will be a DNS name pointing to your load balancer. Select the Default Web Site in the **Web Site** dropdown, or other web site as desired. Accept the default for the **Virtual Directory** and confirm that the application pool for Keyfactor Command that you created earlier appears in the **Application Pool** dropdown. Check or uncheck the **Use SSL** box as appropriate for your environment.

Administration Section

In the Administration section, enter the Active Directory security group or groups that you will use to control administrative access to the Keyfactor Command Management Portal in the **Administrative Users** field. Multiple groups should be separated by commas with no trailing spaces. You may use the people picker button ( ) to browse for groups. Click the verify button ( ) to confirm that any entered groups are valid. Enter only the group(s) to which you want to grant full administrative rights to the Keyfactor Command Management Portal. Following initial configuration, you can create other permission levels and grant those permission levels to other Active Directory users or groups through the Keyfactor Command Management Portal. See Security Roles and Identities on page 577 in the *Keyfactor Command Reference Guide* for more information.

Important: The built-in Active Directory groups Domain Admins and Enterprise Admins cannot be used directly to grant access to the Management Portal due to how these groups function within Windows. You can create a custom Active Directory group, reference that group in the Management Portal, and add the built-in Domain Admins or Enterprise Admins group to that custom group, if desired.

Important: The administrative group must be created as a Global or Universal group. If the administrative group is created as a domain-local group, it will not be recognized by the Management Portal Security Roles and Identities configuration. Configuration of the Management Portal will be incomplete until the group is deleted and recreated as a Global or Universal group.

Enrollment Section

In the Enrollment section of the page, modify the default **Certificate Subject Format** field, if desired. The subject values provided in this field are substituted at processing time for any entered by the user in PFX enrollment or provided with enrollment defaults if the template used is set to supply in request.

The data in the subject format takes precedence over any data entered during PFX enrollment or supplied by enrollment defaults (see Enrollment Defaults Tab on page 349 in the *Keyfactor Command Reference Guide*). For example, if you define the following subject format:

```
CN={CN},E={E},O=Key Example\, Inc.,OU={OU},L=Chicago,ST=IL,C=US
```

The organization for certificates generated through PFX enrollment will always be "Key Example, Inc." regardless of what is shown on the PFX enrollment page during enrollment.

This setting also applies to CSRs generated using the CSR generation method and to CSR and PFX enrollments done using the Classic API.

Data from the default subject *does not* display in the PFX enrollment form. To define defaults that will display in the PFX enrollment form (and can be modified by users), use enrollment defaults (see Enrollment Defaults Tab on page 349 in the *Keyfactor Command Reference Guide*).

Note: Backslashes are required before any commas embedded within values in the subject field (e.g. O=Key Example\, Inc.). Quotation marks should not be used in the strings in the fields except in the case where these are part of the desired subject value, as they are processed as literal values.

Tip: The default subject format *does not* apply to enrollments done using the CSR enrollment method or any requests done with the Keyfactor API.

PFX Enrollment Section

In the PFX Enrollment section of the page, uncheck the **Enabled** box if you do not wish to support PFX enrollment. If you wish to support PFX enrollment, leave the **Enabled** box checked. Select the **Domain** radio button

if you wish PFX files to be protected with the user's Active Directory password or select the **Auto-Generated** radio button if you wish PFX files to be protected with a one-time password. Check the **Alphanumeric Password Characters** box if you wish the one-time password used to protect PFX files to contain numbers and letters. Uncheck the **Alphanumeric Password Characters** box if you wish the one-time password used to protect PFX files to contain numbers, letters and special characters. In the **Password Length** field, enter a number for the number of characters the one-time password should have. The minimum value is 8. If you select the **Domain** radio button, the data entered in the password fields is not relevant.

CSR Enrollment Section

In the CSR Enrollment section of the page, uncheck the **Enabled** box if you do not wish to support CSR enrollment. If you wish to support CSR enrollment, leave the **Enabled** box checked.

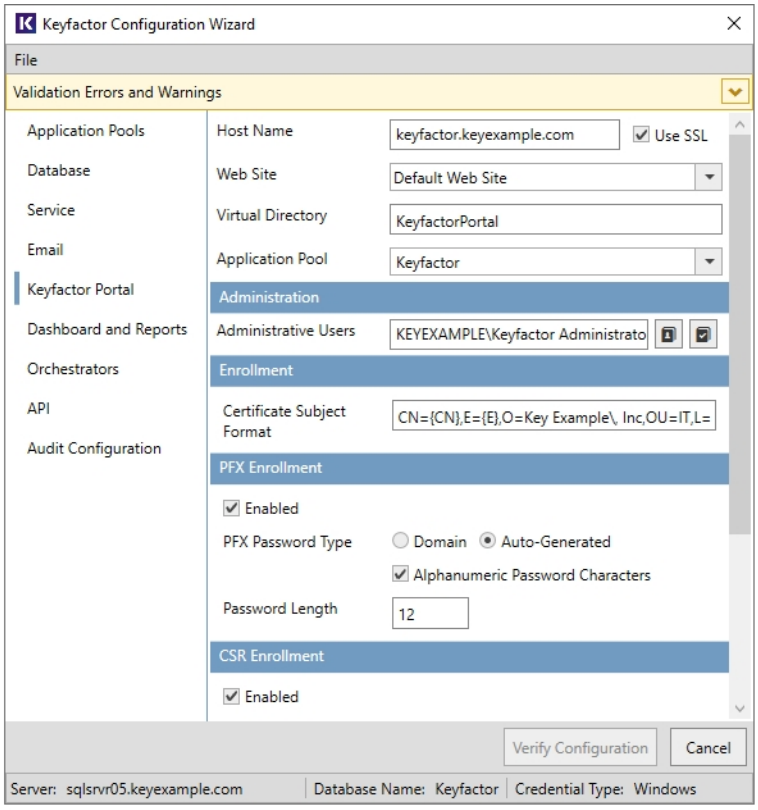

Figure 463: Configure: Keyfactor Portal

17. Dashboard and Reports Tab

    On the Dashboard and Reports tab, enter the FQDN of the server hosting the Keyfactor Command Management Portal—where the Logi Analytics Platform is installed—in the **Host Name** field. This can be either the actual host name of the server on which you are installing the Keyfactor Command Management Portal component or a DNS alias pointing to the server. Check or uncheck the **Use SSL** box as appropriate for your

environment. Select the Default Web Site in the **Web Site** dropdown, or other web site as desired. Accept the default for the **Virtual Directory** and confirm that the application pool for Keyfactor Command that you created earlier appears in the **Application Pool** dropdown. In the **Keyfactor Site IP Address(es)** field, enter the IPv4 (and IPv6 (if applicable), separated by a comma) IP address(es) of the server hosting the Keyfactor Command Management Portal in a comma-delimited list. If you plan to use integrated Windows authentication (see Configure Kerberos Authentication on page 2286) to access the Management Portal, uncheck the **Use Basic Authentication** box. If you plan to use Basic authentication to access the Management Portal, check the **Use Basic Authentication** box and enter the user name (DOMAIN\username format) and password of the Active Directory service account that the Logi Analytics Platform will use to access Keyfactor Command (using the Keyfactor API). This can be the same service account used for the application pool or a different service account. You may use the people picker button ( ) to browse for the account. Click the verify button ( ) to confirm that the username and password entered are valid.

Note: If desired, you can configure the **Host Name** field as *localhost* and then configure the **Keyfactor Site IP Addresses(es)** field as *127.0.0.1,::1* (to cover both the IPv4 and IPv6 loopback addresses). You cannot mix and match actual host names and IP addresses with localhost and loopback addresses—e.g. setting **Host Name** to *keyfactor.keyexample.com* and **Keyfactor Site IP Address(es)** to *127.0.0.1,::1* will not work.

Note: If you are installing the Management Portal in a load balanced configuration, see Appendix - Logi Load Balancing: Keyfactor Command Configuration Wizard Setup on page 2351.

Note: If you do not enter ::1 (the loopback address for IPv6) in the **Keyfactor Site IP Address(es)** field, the configuration wizard automatically appends this for you. Having extra names and/or addresses by which the Management Portal might be known in this field allows Logi to connect to Keyfactor Command in the most scenarios possible.

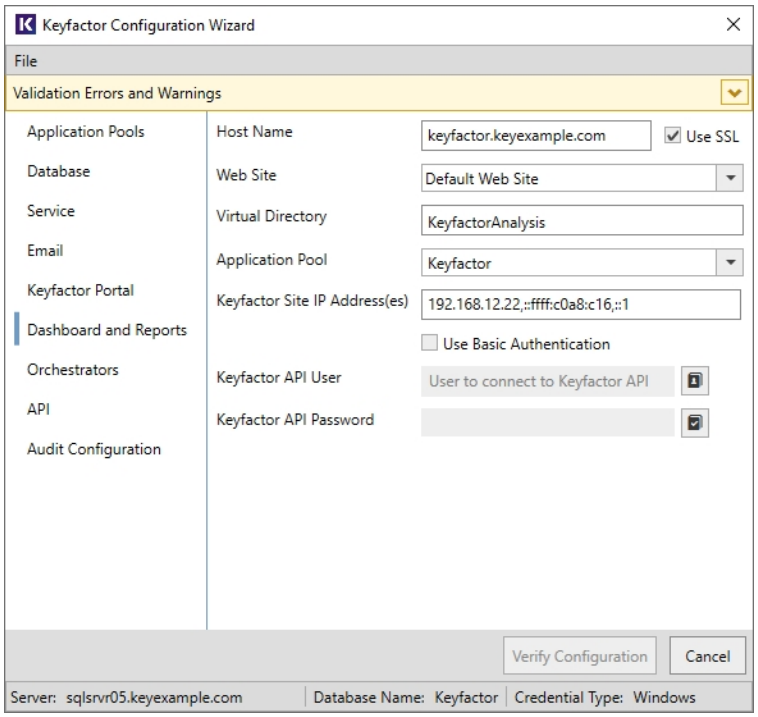

Figure 464: Configure: Dashboard and Reports

18. vSCEP Services Tab

    On the vSCEP Service tab (this tab won't appear if you installed only the default components), enter the FQDN of the server hosting the Keyfactor Command vSCEP™ service in the **Host Name** field. This can be either the actual host name of the server on which you are installing the Keyfactor Command Services (vSCEP Validation Service) components or a DNS alias pointing to the server. Check or uncheck the **Use SSL** box as appropriate for your environment. Select the Default Web Site in the **Web Site** dropdown, or other web site as desired. Accept the default for the **Virtual Directory** and confirm that the application pool for Keyfactor Command that you created earlier appears in the **Application Pool** dropdown. Select a certificate template you will use with this service in the **SCEP Certificate Template** dropdown. Enter the full path to the SCEP challenge page for the SCEP server in the SCEP Path field. This path should be given in full URL format as follows (where MICROSOFT_NDES_SERVER_FQDN is the FQDN of your Microsoft NDES server or Keyfactor_SCEP_SERVER_FQDN is the FQDN of your Keyfactor SCEP server):

    - For Microsoft NDES:

      ```
      https://[MICROSOFT_NDES_SERVER_FQDN]/certsrv/mscep_admin
      ```

    - For Keyfactor SCEP:

      ```
      https://[KEYFACTOR_SCEP_SERVER_FQDN]/scep/challenge
      ```

    Your Microsoft NDES or Keyfactor SCEP server may have been configured to use HTTP rather than HTTPS. Enter the full path to the SCEP enrollment page for the SCEP server in the **Request Path** field. This path should

be given in full URL format as follows (where MICROSOFT_NDES_SERVER_FQDN is the FQDN of your Microsoft NDES server or Keyfactor_SCEP_SERVER_FQDN is the FQDN of your Keyfactor SCEP server):

- For Microsoft NDES:

  ```
  https://[MICROSOFT_NDES_SERVER_FQDN]/certsrv/mscep/mscep.dll
  ```

- For Keyfactor SCEP:

  ```
  https://[KEYFACTOR_SCEP_SERVER_FQDN]/scep/api/scep
  ```

Your Microsoft NDES or Keyfactor SCEP server may have been configured to use HTTP rather than HTTPS.

Enter the Active Directory security group or groups that you will use to control access to the vSCEP API in the **Allowed Users/Groups** field or enter individual users (DOMAIN\username or DOMAIN\group name format). You may use the people picker button ( ) to browse for users or groups. Click the verify button ( ) to confirm that any entered users or groups are valid.

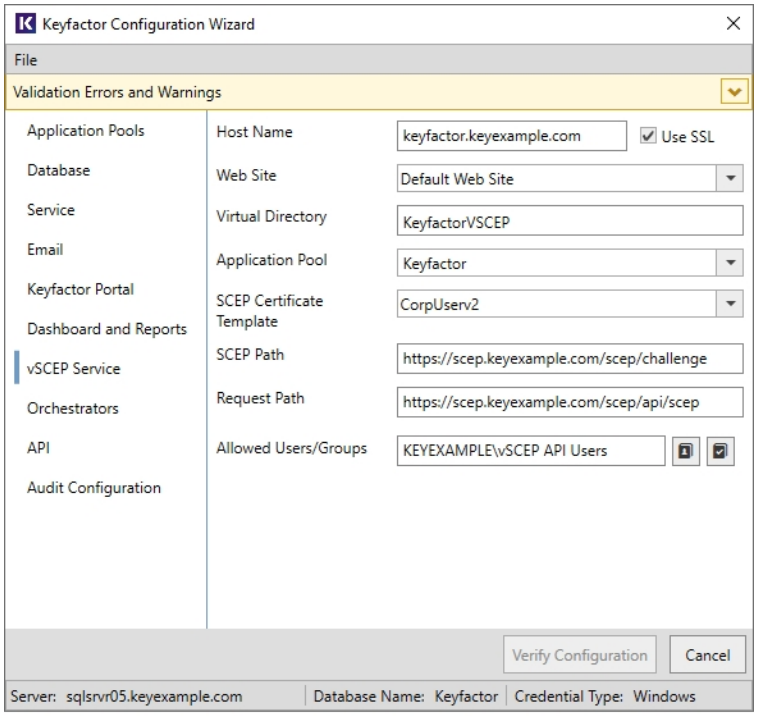

Figure 465: Configure: vSCEP Service

19. Orchestrators

    On the Orchestrators tab, enter the FQDN of the server hosting the Keyfactor Command orchestrators web site in the **Host Name** field. This can be either the actual host name of the server on which you are installing the Keyfactor Command Services (Orchestrator Services API) components or a DNS alias pointing to the server. Select the Default Web Site in the **Web Site** dropdown, or other web site as desired. Accept the default for the **Virtual Directory** and confirm that the application pool for Keyfactor Command that you created

earlier appears in the **Application Pool** dropdown. Check or uncheck the **Use SSL** box as appropriate for your environment.

Reenrollment Section (Optional)

In the **Template For Submitted CSRs** field, from the dropdown, select the template to be used for reenrollment requests made from the Certificate Stores page.

In the **CA For Submitted CSRs** field, enter the certificate authority used for reenrollment requests made from the Certificate Stores page. The CA should be entered in the format FQDN\Logical Name.

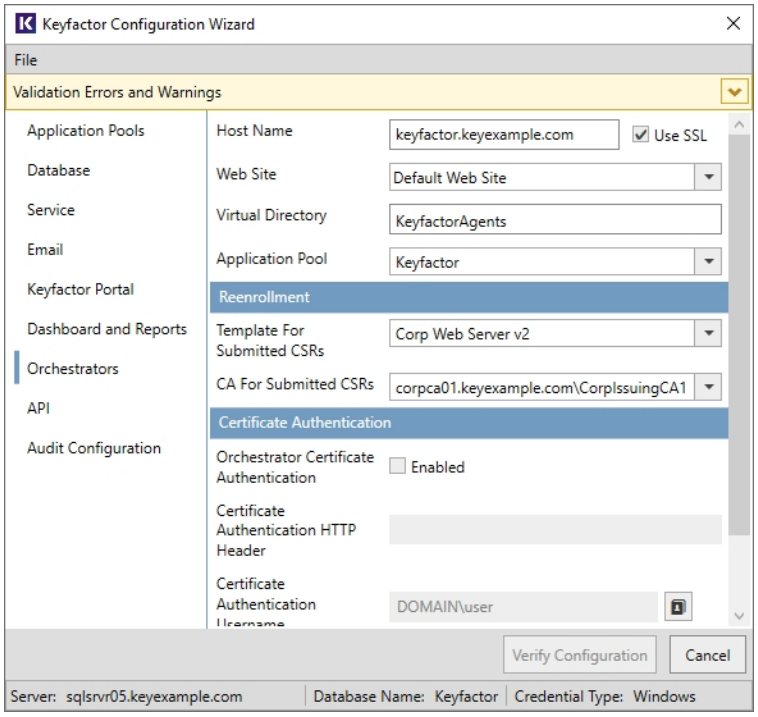

Figure 466: Configure: Orchestrators with Standard Authentication

Certificate Authentication Section (Optional)

In the Certificate Authentication section of the Orchestrators tab, check the **Enabled** box if you wish to support client certificate enrollment from the Keyfactor Universal Orchestrator or Keyfactor Windows Orchestrator. In the **Certificate Authentication HTTP Header** field, enter the HTTP header under which the orchestrator connection proxy should send the client authentication certificate. Keyfactor Command uses the certificate supplied in this header to identify the orchestrator attempting to authenticate. In the **Certificate Authentication Username** and **Certificate Authentication Password** fields, enter the credentials for the Active Directory user configured on the proxy to authenticate the orchestrator(s) to the Keyfactor Command server.

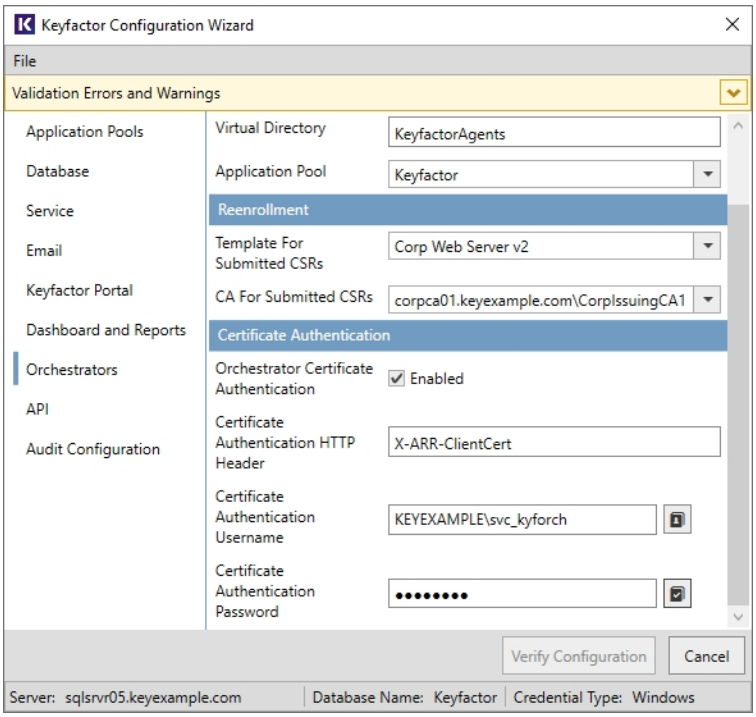

Figure 467: Configure: Orchestrators with Client Certificate Authentication

20. API Tab

    On the API tab, enter the FQDN of the server hosting the Keyfactor Command KeyfactorAPI service in the **Host Name** field. This can be either the actual host name of the server on which you are installing the Keyfactor Command Services (Keyfactor API) components or a DNS alias pointing to the server. Select the Default Web Site in the **Web Site** dropdown, or other web site as desired. Accept the default for the **Virtual Directory** and confirm that the application pool for Keyfactor Command that you created earlier appears in the **Application Pool** dropdown. Check or uncheck the **Use SSL** box as appropriate for your environment.

Classic API Section

In the Classic API section of the API page, check the **Enabled** box if you wish to make use of the Classic API (a.k.a. the CMS API). The classic API may be needed in your environment if you're upgrading from a previous version of Keyfactor Command and have written API applications using the classic API. Enter the FQDN of the server hosting the Keyfactor Command Classic API service in the **Host Name** field. This can be either the actual host name of the server on which you are installing the Keyfactor Command Services (Classic API) components or a DNS alias pointing to the server. Select the Default Web Site in the **Web Site** dropdown, or other web site as desired. Accept the default for the **Virtual Directory** and confirm that the application pool for Keyfactor Command that you created earlier appears in the **Application Pool** dropdown. Check or uncheck the **Use SSL** box as appropriate for your environment.

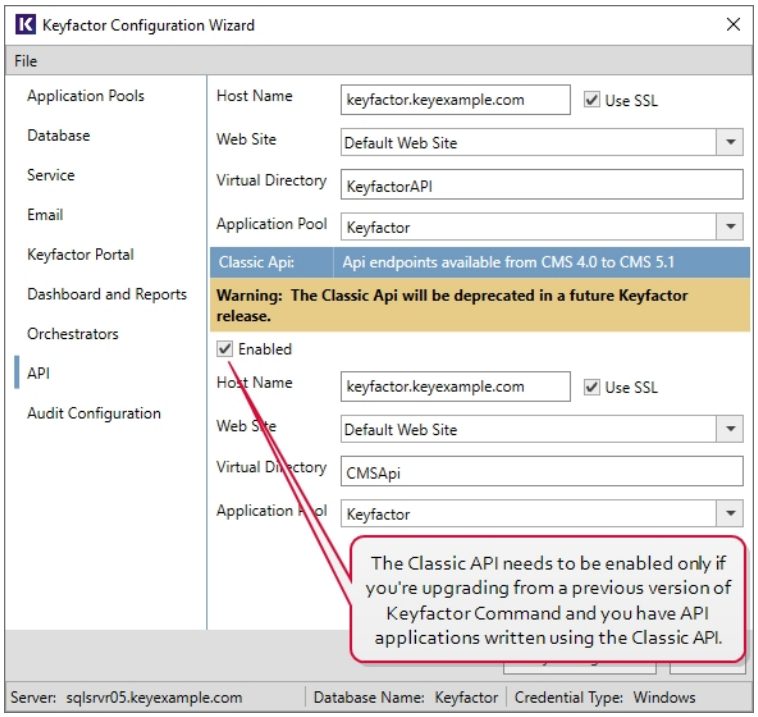

Figure 468: Configure: APIs

21. Auditing Configuration Tab

    On the Auditing Configuration tab, enter the number of years to retain audit data in the **Audit Entry Retention Period (years)** field. By default, seven years of data is retained. The audit log cleanup job runs once daily and removes any audit log entries older than the time specified in the retention parameter except those in the following protected categories:

    - Security
    - CertificateCollections
    - ApplicationSettings
    - SecurityIdentities
    - SecurityRoles

Linux SysLog Server Section

In the Linux SysLog Server section of the page, check the **Connect to SysLog** to enable the option to copy audit logs in real time to a separate server for collection and analysis with a centralized logging solution (e.g. rsyslog, Splunk, Elastic Stack). In the **Host Name** field, enter the fully qualified domain name of the server that will be receiving the logs. Set the **Port** to the port on which your log receipt application is listening to receive the logs. The default value is 514 (the default rsyslog port). If desired, turn on **Use TLS SysLogging**. When you click **Save**, Keyfactor Command will verify that a connection can be made to the specified server on the specified port. Additional configuration on both the Keyfactor Command server and log receipt server are

needed to make TLS communications work (see Prepare for External Log Shipping over TLS (Optional) on page 2248). If you have not yet completed these configurations, you will receive a validation error on save if the Use TLS SysLogging option is enabled.

The auditing settings can be updated on the auditing tab of the applications settings page following installation (see Application Settings: Auditing Tab on page 559 in the *Keyfactor Command Reference Guide*).

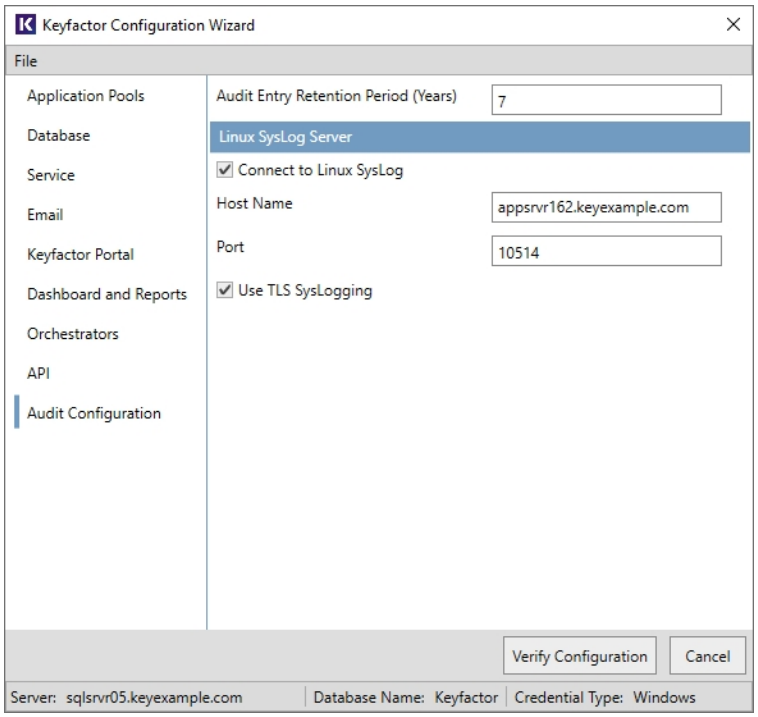

Figure 469: Configure: Audit

22. At this point in the configuration, if you have populated all the required fields, the yellow warning banner at the top of the configuration wizard should have disappeared. If it is still visible, click the dropdown arrow to open the Warnings page and review the warning(s) to see what needs to be corrected. Under some circumstances you will be allowed to continue with the configuration even if the yellow warning banner is still present. You will know this is the case if the **Verify Configuration** button is active. Under these circumstances, you should review the warnings before continuing.

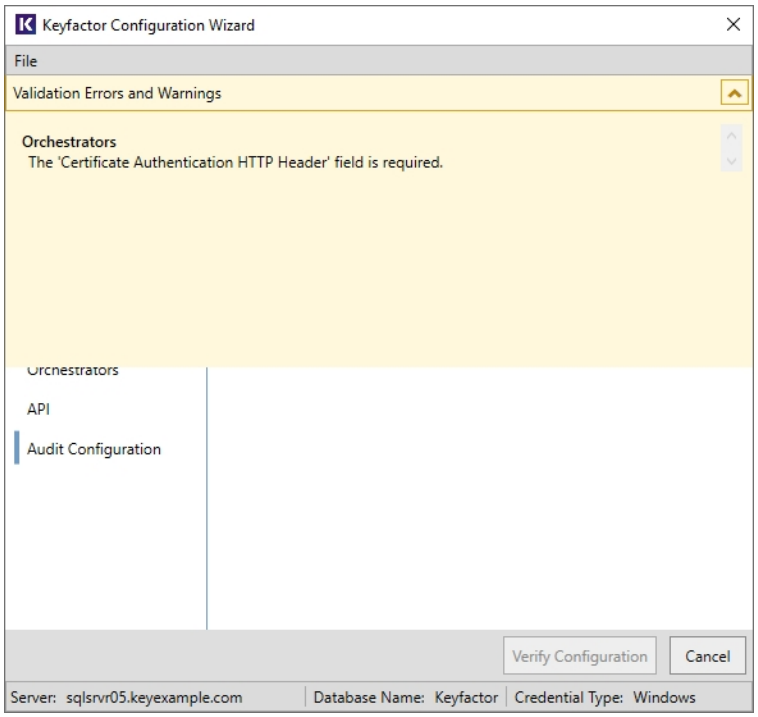

Figure 470: Configure: Configuration Warnings

23. Before completing the configuration wizard, you may choose to save a copy of the configuration as a file for future use. To download the configuration as a file, in the configuration wizard, click **File** at the top of the wizard and choose **Save Data File**. Browse to a location where you want to save the configuration file, enter a file name and click **Save**. You will be prompted to enter a password to encrypt the data in the file. You may choose to protect the file with a password or not. If you use a password at this time, you will need to provide this password to open the file. Keyfactor strongly recommends using a password to protect production files. If you do not wish to use a password to protect a production file, you may edit the file to remove the sensitive information (passwords for the service accounts entered in the configuration wizard). Once you enter a password or uncheck the encryption box, click **OK** to save the file.

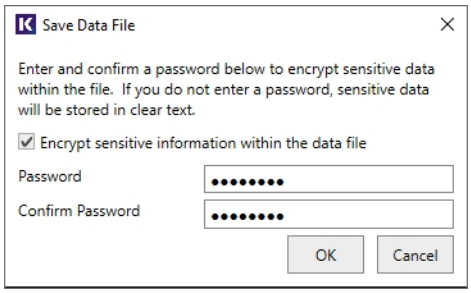

Figure 471: Configure: Save Configuration as a File

24. At the bottom of the Keyfactor Command Configuration Wizard dialog, click **Verify Configuration**.

25. On the Configuration Operations page, review the planned operations and then click **Apply Configuration**. Prior to clicking **Apply Configuration**, you can revisit any of the Configuration Wizard tabs to review or make changes by clicking **Edit Configuration**.

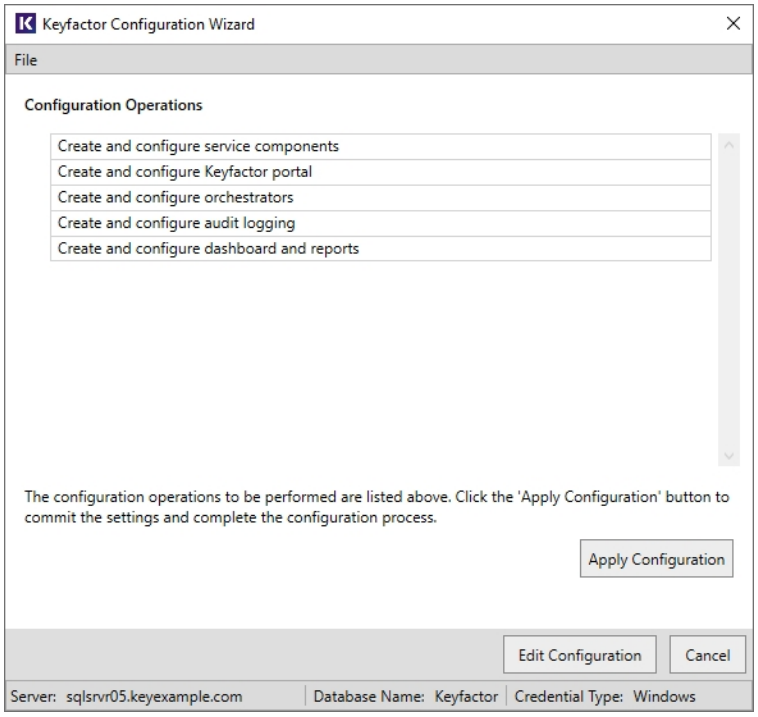

Figure 472: Configure: Configuration Operations

26. When the configuration completes successfully, you will see the below message. If you didn't save a copy of the configuration earlier, you may do so at this time by clicking **Save Settings**. Otherwise, click **Close** to close the dialog.

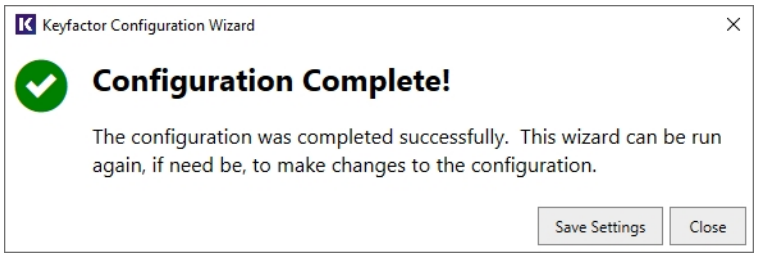

Figure 473: Configure: Configuration Complete

4.4.3.2 Install the Keyfactor Command Server from the Command Line

The Keyfactor Command server can optionally be configured using a pair of configuration files and a command run from the command line. You may be provided one or both of these files by your Keyfactor Customer Success Manager. The configuration files for command-line configuration are:

- Keyfactor Command Configuration File

  This file, with an extension of .cmscfg, contains information in XML format to configure the Keyfactor Command database. This file can be generated by installing Keyfactor Command, running the configuration wizard and populating all the fields as desired, and then saving a copy of the configuration either with or without a password to encrypt sensitive information in the file (see Install the Main Keyfactor Command Components on the Keyfactor Command Server(s) on page 2253). Keyfactor strongly recommends using a password to protect production files.

- Input Parameters File

  This file, with an extension of .xml, contains information in XML format to connect to and configure SQL, open the Keyfactor Command configuration file, locate the Keyfactor Command license, and create application pools, if desired.

To configure and optionally install Keyfactor Command from the command line:

1. Install the Keyfactor Command software using one of these methods:

   - Follow the initial instructions for Install the Main Keyfactor Command Components on the Keyfactor Command Server(s) on page 2253 except on the final installation wizard page, uncheck the *Launch the Configuration Wizard now* box and click **Finish**. The configuration wizard should not open.
   - Open an administrative command prompt and execute a command similar to the following:

     ```
     start /wait msiexec /i <full path to install file>\KeyfactorPlatform.msi /Live
     <path for msiexec logs> /Quiet
     ```

     This will install the default components of Keyfactor Command in a non-interactive way (/Quiet), output log information to a file (/Live), and wait to return to the command prompt until the installation is complete (start /wait).

     If you wish to install a set of features other than the default features, you can add the ADDLOCAL parameter and specify the features you wish to install. For example, the following command will install the *Orchestrator Service API* and *Windows Services* features:

     ```
     start /wait msiexec /i <full path to install file>\KeyfactorPlatform.msi
     ADDLOCAL=AgentServicesFeature,ServiceFeature /Live <path for msiexec logs> /Quiet
     ```

     The following features are available:

     - AgentServicesFeature

       This installs the Orchestrator Service API feature.

     - ConfigurationFeature

       This installs the configuration wizard and is required for all installations.

     - ServiceFeature

       This installs the Windows Services feature, which includes the Keyfactor Command Service (a.k.a. the timer service).

     - VCRedistFeature

       This installs the Microsoft Visual C++ Redistributable and is required for all installations unless it has been separately installed.

     - vSCEPValidationFeature

This installs the vSCEP Validation Service feature. It is not included in the default features.

- WebApiFeature

  This installs the WebAPI feature, which includes both the Keyfactor API and the Classic API.

- WebConsoleFeature

  This installs the Management Portal feature, which includes the Keyfactor Command Management Portal and the Keyfactor API.

The features you decide to install will depend on the role the server will be playing in your Keyfactor Command implementation. Table 764: Features Required for Each Server Role shows the minimum features that need to be installed for each of the server roles shown in the table columns. If you're installing all the required features on a single server, you need everything except *vSCEPValidationFeature*, which is only required for customers needing to validate SCEP requests, and *WebApiFeature*, which is only required for customers wishing to use the Classic API (see Classic API on page 2106 in the *Keyfactor Web APIs Reference Guide*). If you don't intend to use any orchestrators (see Installing Orchestrators on page 2355 in the *Keyfactor Orchestrators Installation and Configuration Guide*), you do not need to install the *AgentServicesFeature*.

Table 764: Features Required for Each Server Role

ADDLOCAL Parameter	Single Server	Management Portal	Windows Services	WebAPI	Orchestrator Service API	vSCEP Validation Service
ConfigurationFeature	✓	✓	✓	✓	✓	✓
VCRedistFeature	✓	✓	✓	✓	✓	✓
WebConsoleFeature	✓	✓				
ServiceFeature	✓		✓			
WebApiFeature				✓		
AgentServicesFeature	✓				✓	
vSCEPValidationFeature						✓

2. Acquire a Keyfactor Command configuration file from your Keyfactor Customer Success Manager or create one by installing and configuring Keyfactor Command on a test machine. It's not practical to attempt to generate this file manually, though a file can be edited once generated (other than password-protected fields).

3. Create an input parameters file. See Table 765: Input Parameters XML File Fields. A sample file can be found in the Configuration directory under the directory in which you installed Keyfactor Command. By default, this is:

    C:\Program Files\Keyfactor\Keyfactor Platform\Configuration\InputParameters.xml

4. Open an administrative command prompt, change to the Configuration directory under the directory in which you installed Keyfactor Command (by default this is C:\Program Files\Keyfactor\Keyfactor Platform\Configuration), and execute a command similar to the following, referencing your input parameters file and using the appropriate parameters for the ConfigurationWizardConsole tool (see Table 766: ConfigurationWizardConsole.exe Options):

    .\ConfigurationWizardConsole.exe -p C:\Stuff\InputParameters.xml -u

Tip: Check the Keyfactor Command log and the Windows application event log for errors if the installation does not complete successfully (see Configure Logging on page 2293).

Table 765: Input Parameters XML File Fields

Parameter	Description
Protected	A Boolean indicating whether sensitive information in the Keyfactor Command configuration file is protected with a password (true) or not (false).
Password	A string containing the password used to protect the Keyfactor Command configuration file if *Protected* is set to **true**.
ConfigurationFile	The full path to the Keyfactor Command configuration file (e.g. C:\Stuff\-myconfig.cmscfg).
DatabaseServer	The hostname or IP address of the SQL server where the Keyfactor Command database will be installed, with optional port. For example: • Local: mysql.keyexample.com • Azure SQL myazuresql.database.windows.net,1433
Database	The name of the database in SQL for Keyfactor Command. If a database with this name exists, it will be used (see *ForceDatabaseConversion*). If it doesn't, it will be created (see *CreateDatabaseIfMissing*).
CreateDatabaseIfMissing	A Boolean indicating whether the SQL database should be created if it does not exist (true) or not (false). If this is set to **false** and a database does not exist, an error will be generated and the configuration will not continue.
ForceDatabaseConversion	A Boolean indicating whether a pre-existing SQL database should be converted for use by Keyfactor Command (true) or not (false). If this is set to **false** and a pre-existing database that has not already been converted for Keyfactor Command use is found, an error will be generated and the configuration will not continue.
ForceDatabaseUpgrade	A Boolean indicating whether a pre-existing SQL database should be upgraded from a previous version of Keyfactor Command (true) or not (false). If this is set to **false** and a pre-existing database that is running a version of Keyfactor Command that does not match the version being installed is found, an error will be generated and the configuration will not continue.
ContinueOnSqlGrantError	A Boolean indicating whether the configuration should continue if an error is encountered when attempting to set SQL permissions.
SqlUsername	A string containing the SQL username to be used to authenticate to the SQL server if you have opted not to use Windows integrated authentication. For an on-premise SQL server, the server must be configured to support mixed mode authentication in order to use the SQL option. This option is typically used to connect to cloud-based (e.g. Azure) SQL servers. Leave this field blank if you are using Windows integrated authentication. The credentials of the logged on user executing the command will be used to authen-

Parameter	Description
	ticate to SQL.
SqlPassword	A string containing the SQL password to be used to authenticate to the SQL server. Leave this field blank if you are using Windows integrated authentication.
LicenseFile	The full path to your Keyfactor Command license file (e.g. C:\Stuff\keyexample.cmslicense).

AppliationPoolsToCreate	An array of application pools to create (typically only one is needed). Application pool fields include:
	
	Parameter / **Description**
	Name — A string containing the name of the application pool to create.
	Username — A string containing the user name (DOMAIN\username format) of the Active Directory service account under which the application pool will run.
	Password — A string containing the password of the Active Directory service account under which the application pool will run.
	FailIfExists — A Boolean indicating whether the configuration will fail if the application pool already exists (true) or not (false).
	
	For example:
	
	`<ApplicationPoolsToCreate>`
	`<!--Remove this section if none are to be created-->`
	`<WizardApplicationPool>`
	`<Name>Keyfactor</Name>`
	`<Username>KEYEXAMPLE\svc_keyfactorpool</Username>`
	`<Password>MySecurePassword</Password>`
	`<FailIfExists>true</FailIfExists>`
	`</WizardApplicationPool>`
	`</ApplicationPoolsToCreate>`

Table 766: ConfigurationWizardConsole.exe Options

Switch	Description
-p, --paramfile	The full path to the input parameters XML file. This switch is **required**.
-u, --unattended	Do not output errors at the console. Errors will be redirected to the Windows event log.
-d, --database	Create the database in SQL but do not configure Keyfactor Command.
-s, --scriptpath	The full path to a non-standard location for the scripts used during a database upgrade. By default, these are found in the following path: `C:\Program Files\Keyfactor\Keyfactor Platform\Configuration\DatabaseUpgrade` This option is typically only used by Keyfactor Support.
--help	Display the help.
--version	Display the version information.

4.4.4 Initial Configuration

Once the installation and configuration wizards are complete, only a few configuration tasks remain before Keyfactor Command will be up and running at a basic level. This section details the basic post-install configuration steps that need to be completed to get Keyfactor Command up and running. See the *Keyfactor Command Reference Guide* for more advanced configuration guidance. See the separate installation guides for client components such as the Keyfactor Universal Orchestrator, Keyfactor Windows Orchestrator, Keyfactor Java Orchestrator, and Keyfactor CA Gateways.

After you have completed all the steps in this guide, the certificate search and report functions in the Keyfactor Command Management Portal should be functioning. Further configuration, as described in the *Keyfactor Command Reference Guide*, is required to make these features function:

- Using the Keyfactor Command Management Portal Dashboard on page 6
- Configuring Enrollment through the Keyfactor Command Management Portal (see Certificate Template Operations on page 334)
- Security Roles and Identities on page 577 for the Keyfactor Command Management Portal
- Revocation Monitoring on page 187, Expiration Alerts on page 151 and Pending Certificate Request Alerts on page 161
- Using the Workflow Builder (see Workflow on page 205)
- External Certificate Synchronization with SSL Discovery on page 418 and Certificate Stores on page 358
- Managing SSH on page 479 Keys

4.4.4.1 Configure Kerberos Authentication

By default, the Keyfactor Command Management Portal uses integrated Windows authentication. Integrated authentication consists of both NTLM and Kerberos authentication types. In some environments, NTLM will work for integrated authentication and users will be able to open the Keyfactor Command Management Portal without further configuration, though not all aspects of the portal support NTLM, including the dashboard and enrollment. In other environments, NTLM will not work at all for the portal, so only Kerberos will be supported. Further configuration is required to make Kerberos authentication work correctly. Even if NTLM is supported and you don't intend to use the portions of the portal that don't work with NTLM, Kerberos is generally preferred for best security practice.

Common scenarios in which NTLM will not work are multi-domain forests and authentication attempts between domains and servers that support only NTLMv2 using clients attempting NTLM.

Configuring the environment to support Kerberos includes these topics:

- Configure browsers to support Integrated Windows Authentication
- Configure the service principal name (SPN) for the Keyfactor Command server
- Configure Kerberos constrained delegation (optional)

Note: Basic authentication can be used instead of integrated Windows authentication.

Configure Browsers for Integrated Windows Authentication

To support integrated Windows authentication using either NTLM or Kerberos, the browser must be configured correctly to support this integration. This becomes particularly important when only Kerberos is used, as the browser won't allow the user to continue if Kerberos authentication fails, whereas with NTLM authentication, the integration won't work (the user will be prompted to enter a password), but the user will be allowed to continue to the Keyfactor Command portal. Many modern browsers support integrated authentication. The following instructions cover adding the Keyfactor Command server to Window's trusted sites to support integrated authentication for Microsoft Edge and Google Chrome. Configuring Firefox to support integrated authentication is beyond the scope of this guide.

Important: Internet Explorer is no longer supported for Keyfactor Command. For a list of supported browsers, see System Requirements on page 2217.

To configure Windows to support integrated authentication:

1. In Windows either do a search for Internet Options or open Control Panel or Settings and locate Internet Options.
2. In Internet Options, go to the Security tab.
3. On the Security tab, highlight **Local intranet** and click **Sites**.
4. On the Local intranet sites popup, click **Advanced**.

5. On the Local intranet dialog, enter the fully qualified domain name of your Keyfactor Command server and click **Add**.

6. Click **Close** and **OK** until you have closed all the dialogs.

7. Exit your browser (this setting applies to Microsoft Edge and Google Chrome) and open it again to attempt your authentication.

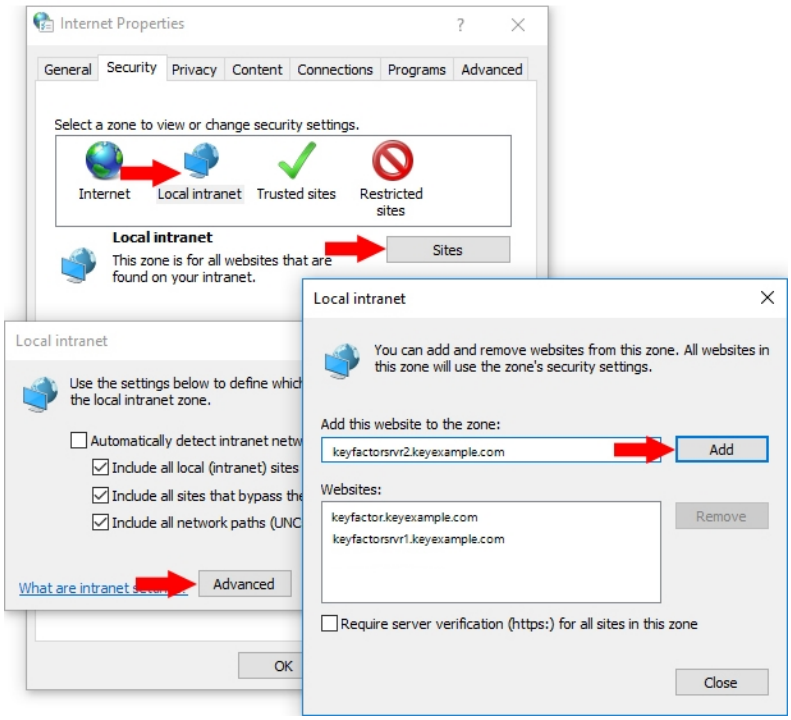

Figure 474: Configure Local Intranet Zone in Internet Properties

Important: It is not sufficient to put the Keyfactor Command server in the **Trusted sites** zone. The server needs to be in the **Local intranet** zone for proper integrated authentication functionality (assuming these zones are still configured as per the default configuration).

Configure the Service Principal Name for the Keyfactor Command Server

On a server that has the setspn command available (typically it is available on domain controllers, as it installs as part of the Active Directory Domain Services role), open a command prompt using the "Run as administrator" option and run the following command (where keyfactor.keyexample.com is the fully qualified domain name of your Keyfactor Command server or the DNS alias you are using to reference your Keyfactor Command server, if applicable, and KEYEXAMPLE\svc_keyfactorpool is the domain name and service account name of the service account under which the Keyfactor Command application pool is running):

```
setspn -s HTTP/keyfactor.keyexample.com KEYEXAMPLE\svc_keyfactorpool
```

Configure Kerberos Constrained Delegation (Optional)

If either of these scenarios is true in your environment, you will need to configure Kerberos delegation to the CAs from the Keyfactor Command server hosting the Keyfactor Command Management Portal:

- You wish to use the option in Keyfactor Command to allow interactions with the CA via the Keyfactor Command Management Portal (e.g. certificate approval or revocation) to be done in the context of the user logged into the Keyfactor Command Management Portal rather than in the context of the Keyfactor Command service account under which the application pool is running or an explicit user configured in the CA configuration within Keyfactor Command.
- You wish to enroll for certificates through the Keyfactor Command Management Portal after authenticating to the portal using Kerberos authentication rather than Basic authentication. If you wish to use the Keyfactor Command Management Portal but don't wish to configure delegation or an explicit user configured in the CA configuration within Keyfactor Command, you will need to set the Keyfactor Command Management Portal to support Basic authentication only.

Configuring Kerberos delegation in Active Directory allows the user's Kerberos credentials to be delegated from the Keyfactor Command server to the CA(s) to allow the Keyfactor Command server to act on behalf of the user.

The types of interactions affected by delegation in the Keyfactor Command Management Portal include:

- Enrollment for certificates
- Approval of pending certificate requests
- Denial of pending certificate requests
- Revocation of certificates
- Certificate key recovery

> **Note:** You have the option to turn off delegation for these functions using the *Delegate* settings on each CA configured in Keyfactor Command (see Authorization Methods Tab on page 322 in the *Keyfactor Command Reference Guide*). Delegation is configured separately for management and enrollment functions.

There are two different approaches to configuring constrained delegation:

- With the traditional version of constrained delegation, you configure the service account under which the Keyfactor Command application pool runs and the machine account of the Keyfactor Command server to be allowed to delegate **to** each of your CAs.
- With the newer resource-based constrained delegation introduced in Windows server 2012, you configure each of your CAs to be allowed to receive delegation **from** the service account under which the Keyfactor Command application pool runs and the machine account of the Keyfactor Command server. This option requires at least one domain controller that's server 2012 or better, though there can be 2008 or 2008 R2 domain controllers in the mix.

With both approaches to constrained delegation, you need to set the service principal name (SPN) for the Keyfactor Command server (see Configure the Service Principal Name for the Keyfactor Command Server on the previous page).

Note: If you're using a Keyfactor CA gateway and the gateway service is running as an Active Directory service account, delegation to that gateway is configured differently than is described below. Refer to the gateway documentation for more information.

Traditional Delegation

Note: Traditional constrained Kerberos delegation across multiple domains is only supported in newer versions of Windows Server for domain controllers. If yours is a multi-domain environment and you cannot locate your CAs following the below instructions, you may need to configure traditional unconstrained Kerberos delegation or configure traditional constrained delegation using ADSIEdit rather than the below method. To configure traditional unconstrained delegation, you would select "Trust this computer for delegation to any service (Kerberos only)" in each of the step 2s, below, and then skip the remainder of the steps in that set of instructions. For assistance configuring traditional constrained delegation using ADSIEdit, contact Keyfactor support (support@keyfactor.com). If none of the traditional constrained delegation methods work in your multi-domain environment, you may need to pursue resource-based constrained delegation instead, which is more forgiving of multi-domain environments.

To configure Kerberos constrained delegation on the machine account of the Keyfactor Command server:

1. Open Active Directory Users and Computers and browse to locate the **machine** account of the Keyfactor Command server and open its properties.
2. On the Delegation tab for the machine account, choose "Trust the computer for delegation to specified services only" and under that "Use any authentication protocol" and then click **Add**.
3. In the Add Services dialog, click **Users or Computers** and browse to locate the computer account for one of the CAs to which you wish to delegate.

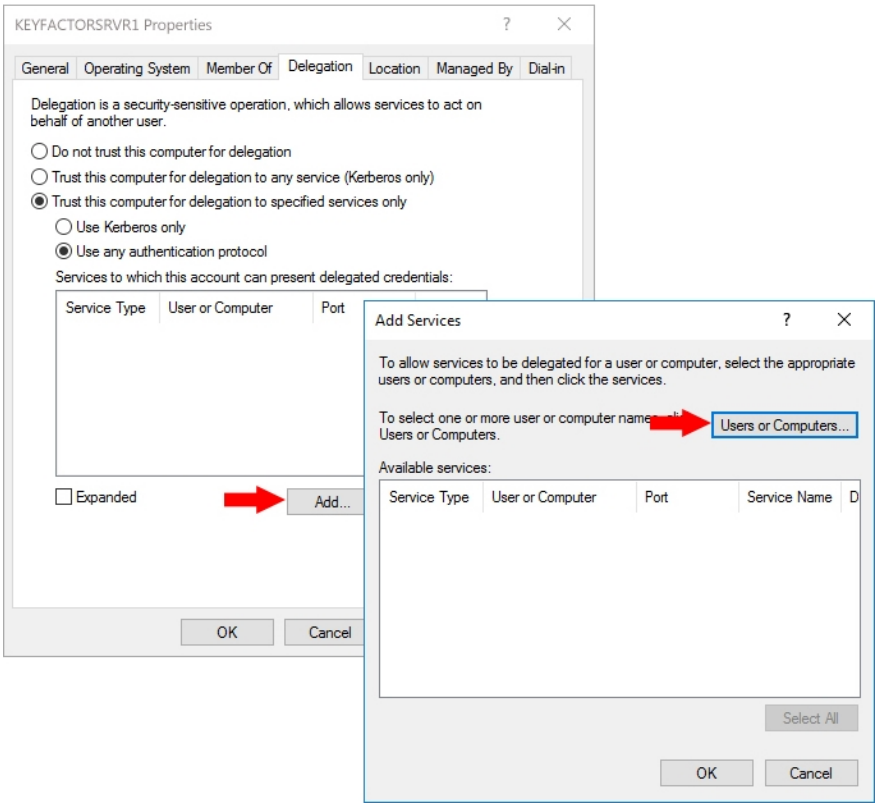

Figure 475: Configure Kerberos Constrained Delegation on the Keyfactor Command Machine Account

4. In the Add Services dialog once the available services have populated, highlight both the **HOST** and the **rpcss** services (hold down the CTRL key when clicking the second service to select both at the same time) and click **OK**.

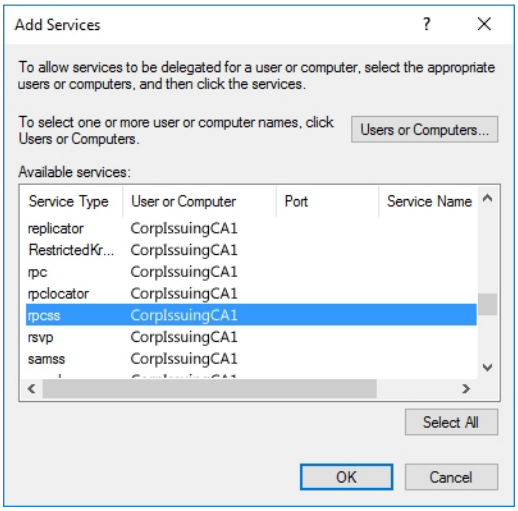

Figure 476: Add HOST and rpcss Service Types for Kerberos Constrained Delegation

5. Back on the Delegation tab of the machine account Properties, you should see the HOST and rpcss services populate the "Services to which this account can present delegated credentials box". The server names do not appear as fully qualified domain names until you close the properties dialog and open it again.

6. Repeat steps 3 and 4 for any other CAs to which you wish to delegate and then click **OK**.

To configure Kerberos constrained delegation on the **service** account under which the Keyfactor Command application pool is running:

1. Open Active Directory Users and Computers and browse to locate the service account under which the Keyfactor Command application pool is running and open its properties.

2. On the Delegation tab for the service account, choose "Trust the computer for delegation to specified services only" and under that "Use Kerberos only" and then click **Add**.

   Important: This is a different configuration setting than for the machine account.

   Tip: The Delegation tab only appears on the properties sheet after you have configured a custom SPN.

3. In the Add Services dialog, click **Users or Computers** and browse to locate the computer account for one of the CAs to which you wish to delegate.

4. In the Add Services dialog once the available services have populated, highlight both the **HOST** and the **rpcss** services (hold down the CTRL key when clicking the second service to select both at the same time) and click **OK**.

5. Back on the Delegation tab of the service account Properties, you should see the HOST and rpcss services populate the "Services to which this account can present delegated credentials box". The server names do not appear as fully qualified domain names until you close the properties dialog and open it again.

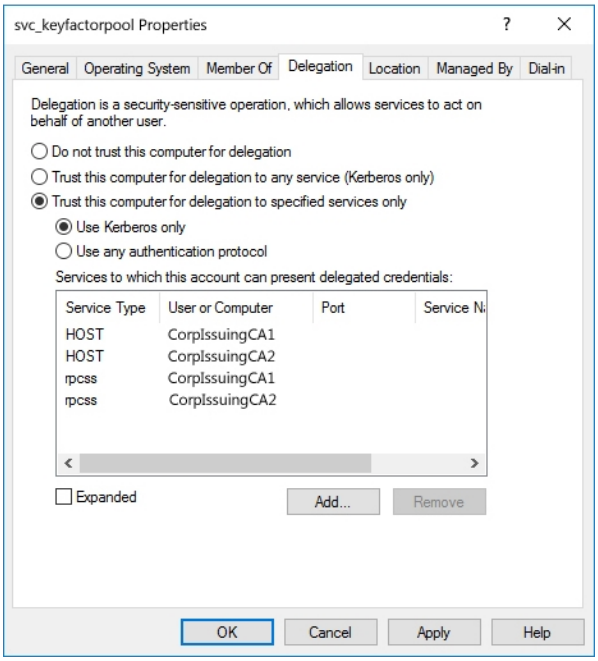

Figure 477: Configure Kerberos Constrained Delegation on the Keyfactor Command Service Account

6. Repeat steps 3 and 4 for any other CAs to which you wish to delegate and then click **OK**.

Resource-Based Delegation

To configure Kerberos resource-based constrained delegation:

1. Create at least one Active Directory security group that will be used for granting delegation permission.

   Tip: The type of group to use and domain to place it in will vary depending on your forest structure and the location of the accounts and resources in the forest. If your Keyfactor Command server(s), CA (s) and application pool service account are all in the same domain, any type of group in that same domain will do. If your Keyfactor Command server(s), CA(s) and/or application pool service account are separated across multiple domains, it becomes more complicated. If you add one or more cross-forest trusts into the mix that you want to do delegation across, that adds another level of complexity. Universal groups cannot be used in a cross-forest scenario, as they are not supported cross-forest. Some possible scenarios include:

   - All components (Keyfactor Command server(s), CA(s) and application pool service account) in the same domain: Create a group of any type in the same domain as these components.
   - Keyfactor Command server(s) and application pool service account in child domain A and all CAs in the parent domain or child domain B with no cross-forest involvement: Create a universal group in the domain with the CAs (the parent domain or child domain B).

- Keyfactor Command server(s), application pool service account and CA(s) for forest A in the same domain, CAs in a single domain in forest B, forests A and B in a two way trust: Create a group of any type in the forest A domain where the Keyfactor Command server(s) reside and a group of type *domain local* in the forest B domain where the CAs reside; follow the below instructions for both domains and groups.

2. Add the service account under which the Keyfactor Command application pool runs to this new security group.
3. Add the machine account for the Keyfactor Command server to this new security group. Repeat for additional Keyfactor Command servers.
4. On an Active Directory domain controller running Windows Server 2012 or better, open a PowerShell window using the "Run as administrator" option. If you're in a multi-domain or cross-forest environment, use a domain controller in the resource domain where the CAs exist.
5. In the PowerShell window, run the following commands, where *KerberosDelegationGroup* is the name of your group for Kerberos delegation and *IssuingCA* is the machine name (no trailing $) of the CA you wish to delegate to:
   ```
   $mygroup = Get-ADGroup -Identity KerberosDelegationGroup
   Set-ADComputer IssuingCA -PrincipalsAllowedToDelegateToAccount $mygroup
   ```
6. Repeat the Set-ADComputer step for any additional CAs.
7. In the PowerShell window, run the following command for each CA to confirm that the group has been associated with the PrincipalsAllowedToDelegateToAccount property on the CA account:
   ```
   Get-ADComputer IssuingCA -Properties PrincipalsAllowedToDelegateToAccount
   ```

4.4.4.2 Configure Logging

Keyfactor Command provides extensive logging for visibility and troubleshooting. By default, Keyfactor Command places its log files in the C:\Keyfactor\logs directory, generates logs at the "Info" logging level and stores the primary logs for two days before deleting them. If you wish to change these defaults you can open the configuration file for each type of log on each Keyfactor Command server where you wish to adjust logging, and edit the file in a text editor (e.g. Notepad) using the "Run as administrator" option. Each component now has its own NLog configuration file and NLog logging output path.

Note: By default, the filename for each component log is unique. This allows you to isolate and research issues on a component-by-component basis by viewing a specific log file. Alternatively, you may wish to change the default output filename to be the same for all logging components so all activity is reported in a single log file. You will note that the default Audit and Alert filenames for each component (for those components that log audits or alerts) are the same so that all activity is logged in the same file across the platform for this reason.

Tip: If you use the default naming convention, and want to review an event that happened in the management portal, for instance, you would look in the Command_API_Log.txt and/or the Command_Portal_Log.txt.

Important: If you do choose to name the log files the same across the platform, it is recommended that you also set the **maxArchiveFiles** values the same in each Nlog config file. If there is a different value for **maxArchiveFiles** for files with the same filename/location, the smallest value will override all others.

The Nlog.config files are located in the installation directory for the product under a subdirectory for the given type of logging. By default, these locations are:

- **C:\Program Files\Keyfactor\Keyfactor Platform\Configuration\NLog_Configuration.config**

  The Configuration file logs activity related to running the Keyfactor Command configuration wizard only.

- **C:\Program Files\Keyfactor\Keyfactor Platform\KeyfactorAPI\NLog_KeyfactorAPI.config**

  The Keyfactor API file is the primary file for logging activity related to running the Keyfactor API. The Keyfactor API is used both for some basic underlying functionality of Keyfactor Command and for any API applications written against it by customers, so the log will show activity related to running the Management Portal as well as external API activity.

- **C:\Program Files\Keyfactor\Keyfactor Platform\Service\NLog_TimerService.config**

  The Service file logs activity related to scheduled and automated events within Keyfactor Command.

- **C:\Program Files\Keyfactor\Keyfactor Platform\WebAgentServices\NLog_Orchestrators.config**

  The Orchestrators, or Orchestrators API, file logs activity related to Keyfactor Orchestrators API.

- **C:\Program Files\Keyfactor\Keyfactor Platform\WebAPI\NLog_ClassicAPI.config**

  The Classsic API file logs activity involving the Classic API from Keyfactor Command.

- **C:\Program Files\Keyfactor\Keyfactor Platform\WebConsole\NLog_Portal.config**

  The Portal file is for logging any activity to do with the Keyfactor Command web portal. Keyfactor is migrating the product to use mostly the Keyfactor API, so this file will have less activity going forward. See C:\Program Files\Keyfactor\Keyfactor Platform\KeyfactorAPI\NLog_KeyfactorAPI.config above

Once configured, output from the file locations defined will look similar to this:

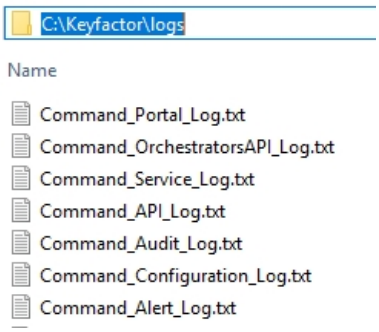

Figure 478: C:\Keyfactor\logs logs

NLog_Configuration.config

The Configuration file logs activity related to running the Keyfactor Command configuration wizard only. The fields you may wish to edit are:

- fileName="C:\Keyfactor\logs\Command_Configuration_Log.txt"

  The path and file name of the active Keyfactor Command configuration wizard log file.

  > **Important:** If you choose to change the path for storage of the log files, you will need to create the new directory (e.g. D:\KeyfactorLogs) and grant both the service account under which the Keyfactor Command Service is running and the service account under which the IIS application pool for Keyfactor Command is running full control permissions on this directory. These roles may be served by the same service account.

- archiveFileName="C:\Keyfactor\logs\Command_Configuration_Log_Archive_{#}.txt"

  The path and file name of previous days' Keyfactor Command configuration wizard log files. Keyfactor Command rotates log files daily and names the previous files using this naming convention.

- fileName="C:\Keyfactor\logs\Command_Audit_Log.txt"

  The path and file name of the active Keyfactor Command log file for auditable configuration wizard events. These logs are generated separately from the configuration log events to allow for separate tracking of auditable events. By default, the audit log filename/location for all components is the same to allow for a central source for tracking auditable events across the platform.

- archiveFileName="C:\Keyfactor\logs\Command_Audit_Log_Archive_{#}.txt""

  The path and file name of previous days' Keyfactor Command log files for auditable configuration wizard events.

- maxArchiveFiles="10"

  The number of archive files to retain before deletion. This field is listed multiple times in the NLog_Configuration.config file on a server —once for the main logging section and once for the audit logging section. The default number of files to retain is 10 for the main log and 14 for the audit log. The audit logs are small by default, and retaining a larger number of them shouldn't create a disk space issue.

- archiveAboveSize="52428800"

  The maximum file size of each log file. Once a log file reaches this size (50 MB by default), it will be rotated to archive even if the end of the day has not been reached.

- name="*" minlevel="Info" writeTo="logfile"

  The level of log detail that should be generated. This line applies to all the logs in the configuration file. The default "Info" level logs error and some informational data but at a minimal level to avoid generating large log files. For troubleshooting, it may be desirable to set the logging level to "Debug" or "Trace". Available log levels (in order of increasing verbosity) are:

  - OFF – No logging
  - FATAL – Log severe errors that cause early termination

- ERROR – Log severe errors and other runtime errors or unexpected conditions that may not cause early termination
- WARN – Log errors and use of deprecated APIs, poor use of APIs, "almost" errors, and other runtime situations that are undesirable or unexpected but not necessarily "wrong"
- INFO – Log all of the above plus runtime events (startup/shutdown)
- DEBUG – Log all of the above plus detailed information on the flow through the system
- TRACE – Maximum log information—this option can generate VERY large log files

```

Figure 479: Nlog_Configuration.config

NLog_KeyfactorAPI.config

The KeyfactorAPI file is the primary file for logging activity related to running Keyfactor Command API. The fields you may wish to edit are:

- fileName="C:\Keyfactor\logs\Command_API_Log.txt"

  The path and file name of the active Keyfactor Command primary log file.

  > **Important:** If you choose to change the path for storage of the log files, you will need to create the new directory (e.g. D:\KeyfactorLogs) and grant both the service account under which the Keyfactor Command Service is running and the service account under which the IIS application pool for Keyfactor Command is running full control permissions on this directory. These roles may be served by the same service account.

- archiveFileName="c:\Keyfactor\logs\Command_API_Log_Archive_{#}.txt"

  The path and file name of previous days' Keyfactor Command primary log files. Keyfactor Command rotates log files daily and names the previous files using this naming convention.

- fileName="C:\Keyfactor\logs\Command_Alert_Log.txt"

  The path and file name of the active Keyfactor Command primary log file for alerting events. This entry is only found on servers with the Keyfactor Command Service installed. Info level messages are written to this log whenever alerts (certificate expiration, pending certificate request, issued certificate, denied certificate request, or revocation monitoring) are run either as scheduled tasks or as tests. The log messages include the type of alert (e.g. expiration alert), the recipient of the alert (if an email was scheduled to be sent), and the alert subject line. You can change the level of logging in the log line that references writeTo="alertlogfile". These logs are generated separately from the primary log events to allow for separate tracking and log

shipping of alerting events. By default, the alert log filename/location for all components is the same to allow for a central source for tracking alert events across the platform.

- archiveFileName="c:\Keyfactor\logs\Command_Alert_Log_Archive_{#}.txt""

  The path and file name of previous days' Keyfactor Command primary log files for alert events.

- fileName="C:\Keyfactor\logs\Command_Audit_Log.txt"

  The path and file name of the active Keyfactor Command primary log file for auditable events. These logs are generated separately from the primary log events to allow for separate tracking of auditable events. By default, the audit log filename/location for all components is the same to allow for a central source for tracking auditable events across the platform.

- archiveFileName="c:\Keyfactor\logs\Command_Audit_Log_Archive_{#}.txt""

  The path and file name of previous days' Keyfactor Command primary log files for auditable events.

- name="EmailAlertLogger" minlevel="Info" writeTo="alertlogfile"

  The level of log detail that should be generated for alert events and written to the alert logs.

- maxArchiveFiles="10"

  The number of archive files to retain before deletion. This field is listed multiple times in the NLog_ KeyfactorAPI.config file —once for the main logging section, once for the alert logging section, and once for the audit logging section. The default number of files to retain is 10 for the main log and the synchronization log but 14 for the alert log and audit log. The alert and audit logs are small by default, and retaining a larger number of them shouldn't create a disk space issue.

- archiveAboveSize="52428800"

  The maximum file size of each log file. Once a log file reaches this size (50 MB by default), it will be rotated to archive even if the end of the day has not been reached.

- name="*" minlevel="Info" writeTo="logfile"

  The level of log detail that should be generated. This line applies to all the logs of the KeyfactorAPI file. The default "Info" level logs error and some informational data but at a minimal level to avoid generating large log files. For troubleshooting, it may be desirable to set the logging level to "Debug" or "Trace". Available log levels (in order of increasing verbosity) are:

  - OFF – No logging
  - FATAL – Log severe errors that cause early termination
  - ERROR – Log severe errors and other runtime errors or unexpected conditions that may not cause early termination
  - WARN – Log errors and use of deprecated APIs, poor use of APIs, "almost" errors, and other runtime situations that are undesirable or unexpected but not necessarily "wrong"
  - INFO – Log all of the above plus runtime events (startup/shutdown)
  - DEBUG – Log all of the above plus detailed information on the flow through the system
  - TRACE – Maximum log information—this option can generate VERY large log files

```

Figure 481: Nlog_TimerService.config

NLog_Orchestrators.config

The Orchestrators, or OrchestratorsAPI, file logs activity related to orchestrators API. The fields you may wish to edit are:

- fileName="C:\Keyfactor\logs\Command_OrchestratorsAPI_Log.txt"

  The path and file name of the active Keyfactor Command orchestrators log file.

  Important: If you choose to change the path for storage of the log files, you will need to create the new directory (e.g. D:\KeyfactorLogs) and grant both the service account under which the Keyfactor Command Service is running and the service account under which the IIS application pool for Keyfactor Command is running full control permissions on this directory. These roles may be served by the same service account.

- archiveFileName="C:\Keyfactor\logs\Command_OrchestratorsAPI_Log_Archive_{#}.txt"

  The path and file name of previous days' Keyfactor Command orchestrators log files. Keyfactor Command rotates log files daily and names the previous files using this naming convention.

- fileName="C:\Keyfactor\logs\Command_Alert_Log.txt"

  The path and file name of the active Keyfactor Command orchestrators log file for alerting events. This entry is found on servers with the Keyfactor Command Service installed. Info level messages are written to this log whenever alerts (certificate expiration, pending certificate request, issued certificate, denied certificate request, or revocation monitoring) are run either as scheduled tasks or as tests. The log messages include the type of alert (e.g. expiration alert), the recipient of the alert (if an email was scheduled to be sent), and the alert subject line. You can change the level of logging in the log line that references writeTo="alertlogfile". These logs are generated separately from the general orchestrator events to allow for separate tracking and log shipping of alerting events. By default, the alert log filename/location for all components is the same to allow for a central source for tracking alert events across the platform.

- archiveFileName="C:\Keyfactor\logs\Command_Alert_Log_Archive_{#}.txt""

  The path and file name of previous days' Keyfactor Command orchestrators log files for alert events.

- fileName="C:\Keyfactor\logs\Command_Audit_Log.txt"

  The path and file name of the active Keyfactor Command orchestrators log file for auditable events. These logs are generated separately from the general orchestrator events to allow for separate tracking of auditable

events. By default, the audit log filename/location for all components is the same to allow for a central source for tracking auditable events across the platform.

- archiveFileName="C:\Keyfactor\logs\Command_Audit_Log_Archive_{#}.txt""

  The path and file name of previous days' Keyfactor Command orchestrators log files for auditable events.

- name="EmailAlertLogger" minlevel="Info" writeTo="alertlogfile"

  The level of log detail that should be generated for alert events and written to the alert logs.

- maxArchiveFiles="10"

  The number of archive files to retain before deletion. This field is listed multiple times in the NLog_Orchestrators.config file on a server with the Keyfactor Command Service installed—once for the main logging section, once for the alert logging section, and once for the audit logging section. The default number of files to retain is 10 for the main log and the synchronization log but 14 for the alert log and audit log. The alert and audit logs are small by default, and retaining a larger number of them shouldn't create a disk space issue.

- archiveAboveSize="52428800"

  The maximum file size of each log file. Once a log file reaches this size (50 MB by default), it will be rotated to archive even if the end of the day has not been reached.

  

  Note: The default value for the *archiveAboveSize* setting was significantly larger in versions of Keyfactor Command prior to 7.5. In addition, the default *maxArchiveFiles* value was 2 for the main and CA synchronization logging sections. In environments where the logging level is consistently set at debug level or greater, this change may result in the generation of several log files per day.

- name="*" minlevel="Info" writeTo="logfile"

  The level of log detail that should be generated. This line applies to all the logs of the orchestrators file. The default "Info" level logs error and some informational data but at a minimal level to avoid generating large log files. For troubleshooting, it may be desirable to set the logging level to "Debug" or "Trace". Available log levels (in order of increasing verbosity) are:

  - OFF – No logging
  - FATAL – Log severe errors that cause early termination

      <when condition="ends-with('${logger}', 'AlertsController') and level &lt; LogLevel.Warn" action="Ignore" />
      <when condition="ends-with('${logger}', 'CertStoreController') and level &lt; LogLevel.Warn" action="Ignore" />
    </filters>
  </logger>
</rules>
</nlog>
```

Figure 483: Nlog_Portal.config

NLog_ClassicAPI.config

The ClasssicAPI file logs activity related to invoking the ClassicAPI from Keyfactor Command. The fields you may wish to edit are:

- fileName="C:\Keyfactor\logs\Command_ClassicAPI_Log.txt"

  The path and file name of the active Keyfactor Command classic API log file.

  Important: If you choose to change the path for storage of the log files, you will need to create the new directory (e.g. D:\KeyfactorLogs) and grant both the service account under which the Keyfactor Command Service is running and the service account under which the IIS application pool for Keyfactor Command is running full control permissions on this directory. These roles may be served by the same service account.

- archiveFileName="C:\Keyfactor\logs\Command_ClassicAPI_Log_Archive_{#}.txt"

  The path and file name of previous days' Keyfactor Command classic API log files. Keyfactor Command rotates log files daily and names the previous files using this naming convention.

- fileName="C:\Keyfactor\logs\Command_Alert_Log.txt"

  The path and file name of the active Keyfactor Command classic API log file for alerting events. This entry is found on servers with the Keyfactor Command Service installed. Info level messages are written to this log whenever alerts (certificate expiration, pending certificate request, issued certificate, denied certificate request, or revocation monitoring) are run either as scheduled tasks or as tests. The log messages include the type of alert (e.g. expiration alert), the recipient of the alert (if an email was scheduled to be sent), and the alert subject line. You can change the level of logging in the log line that references writeTo="alertlogfile". These logs are generated separately to allow for separate tracking and log shipping of alerting events. By default, the alert log filename/location for all components is the same to allow for a central source for tracking alert events.

- archiveFileName="C:\Keyfactor\logs\Command_Alert_Log_Archive_{#}.txt""

  The path and file name of previous days' Keyfactor Command classic API log files for alert events.

- fileName="C:\Keyfactor\logs\Command_Audit_Log.txt"

  The path and file name of the active Keyfactor Command classic API log file for auditable events. These logs are generated separately from the general classic API events to allow for separate tracking auditable events. By default, the audit log filename/location for all components is the same to allow for a central source for tracking auditable events across the platform.

- archiveFileName="C:\Keyfactor\logs\Command_Audit_Log_Archive_{#}.txt""

  The path and file name of previous days' Keyfactor Command classic API log files for auditable events.

- name="EmailAlertLogger" minlevel="Info" writeTo="alertlogfile"

  The level of log detail that should be generated for alert events and written to the alert logs.

- maxArchiveFiles="10"

  The number of archive files to retain before deletion. This field is listed multiple times in the Nlog_ClassicAPI.config file —once for the main logging section, once for the alert logging section, and once for the audit logging section. The default number of files to retain is 10 for the main log and the synchronization log but 14 for the alert log and audit log. The alert and audit logs are small by default, and retaining a larger number of them shouldn't create a disk space issue.

- archiveAboveSize="52428800"

  The maximum file size of each log file. Once a log file reaches this size (50 MB by default), it will be rotated to archive even if the end of the day has not been reached.

- name="*" minlevel="Info" writeTo="logfile"

  The level of log detail that should be generated. This line applies to all the logs of the classicAPI file. The default "Info" level logs error and some informational data but at a minimal level to avoid generating large log files. For troubleshooting, it may be desirable to set the logging level to "Debug" or "Trace". Available log levels (in order of increasing verbosity) are:

  - OFF – No logging
  - FATAL – Log severe errors that cause early termination
  - ERROR – Log severe errors and other runtime errors or unexpected conditions that may not cause early termination
  - WARN – Log errors and use of deprecated APIs, poor use of APIs, "almost" errors, and other runtime situations that are undesirable or unexpected but not necessarily "wrong"
  - INFO – Log all of the above plus runtime events (startup/shutdown)
  - DEBUG – Log all of the above plus detailed information on the flow through the system
  - TRACE – Maximum log information—this option can generate VERY large log files

```
<targets>
  <target xsi:type="File" name="logfile" fileName="C:\Keyfactor\logs\Command_ClassicAPI_Log.txt" layout="${longdate} ${logger} [${level}] - ${message}"

```

Figure 484: Nlog_ClassicAPI.config

4.4.4.3 Configure CA Certificate Synchronization

The Keyfactor Command certificate management, notification and reporting features make use of a SQL database containing certificates from many locations, including:

- Certificates synchronized from domain-joined Microsoft CAs in your primary forest and forests with which the forest shares a trust
- Certificates synchronized from non-domain-joined EJBCA and Microsoft CAs
- Certificates synchronized from your domain-joined Microsoft CAs in non-trusted forests
- Certificates automatically imported based on SSL synchronization locations
- Certificates imported via Keyfactor CA Gateways from locations such as Entrust and Symantec clouds
- Manually imported certificates
- Certificates inventoried from certificate stores using Keyfactor Command Orchestrators

In order to get these certificates into the Keyfactor Command database so that you can begin using the management, notification and reporting features, you need to configure—at a minimum—CA synchronization. For more information:

- See Certificate Authorities on page 307 in the *Keyfactor Command Reference Guide* for information on configuring CA synchronization for your Microsoft and EJBCA CAs.
- See SSL Discovery on page 418 in the *Keyfactor Command Reference Guide* for information on configuring SSL discovery and monitoring.
- See the separate documentation for each type of CA gateway you have along with Certificate Authorities on page 307 in the *Keyfactor Command Reference Guide* for information on configuring CA synchronization for your CA gateways.
- See Add Certificate on page 65 in the *Keyfactor Command Reference Guide* for information on manually importing a certificate.
- See Installing Orchestrators on page 2355 in the *Keyfactor Orchestrators Installation and Configuration Guide*

and Orchestrators on page 444 and Certificate Stores on page 358 in the *Keyfactor Command Reference Guide* for information on inventorying certificates from certificate stores.

For information on using the Keyfactor Command Management Portal, see Using the Management Portal on page 2 in the *Keyfactor Command Reference Guide*.

Acquire a Client Certificate for EJBCA CA Authentication

Keyfactor Command uses a client certificate to authenticate to the EJBCA certificate authority to support certificate synchronization, enrollment, and revocation. The certificate that Keyfactor Command uses for authentication needs:

- An extended key usage (EKU) of Client Authentication
- A key usage that includes Digital Signature

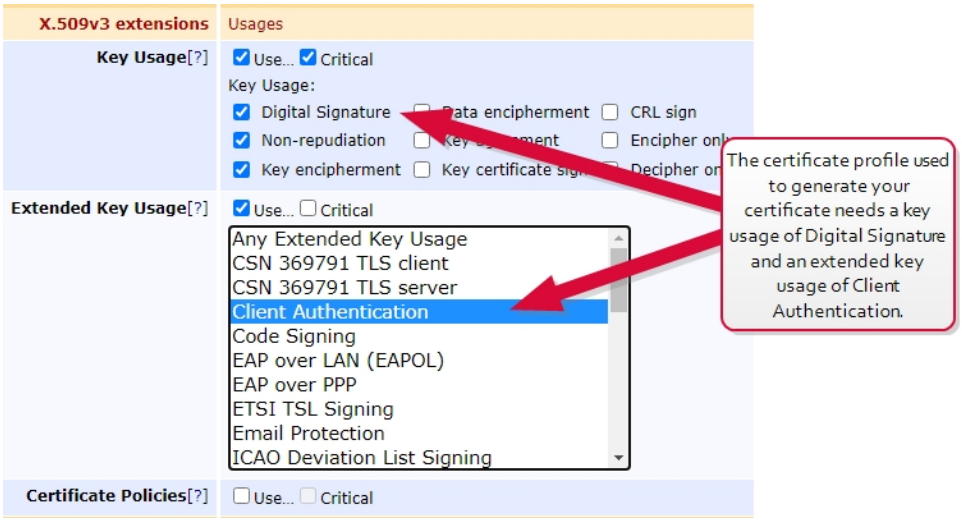

Figure 485: Certificate Profile for EJBCA Client Certificate

The certificate needs to be available as a PKCS#12 (*.pfx) file in order to import it into Keyfactor Command.

Figure 486: Certificate Download for EJBCA Client Certificate

The certificate needs to be granted appropriate access to the EJBCA CA to allow Keyfactor Command interactions with the CA to take place (see Grant the Keyfactor Command Users and Service Account(s) Permissions on the CAs below).

Grant the Keyfactor Command Users and Service Account(s) Permissions on the CAs

In order for Keyfactor Command to be able to synchronize certificates from the CAs to the Keyfactor Command database, the service account under which Keyfactor Command makes a connection to the CA must have permissions to *read* the CA databases. For full Keyfactor Command functionality, additional permissions are needed. The permissions needed vary depending on the type of CA and the type of authorization you intend to configure to allow Keyfactor Command and users in Keyfactor Command to interact with the CA.

Microsoft CAs

When you configure Keyfactor Command access to a Microsoft CA, you have the option to enable the *Use Explicit Credentials* option. When this option is enabled, you enter a set of credentials that will be used specifically to access that Microsoft CA, and all management and enrollment tasks for that CA are done in the context of that service account. If you do not enable the *Use Explicit Credentials* option, management tasks (e.g. revocation, certificate synchronization) and enrollments are done in the context of the service account(s) you configure for the Keyfactor Command Service and the application pool for Keyfactor Command (which are the same service account in many implementations) and individual users. The exact combination of what happens in the context of who depends on the configuration of the delegation options (*Delegate management Operations* and *Delegate Enrollment*) on the CA when the *Use Explicit Credentials* option is not enabled. Delegation is supported for both Basic authentication and Kerberos authentication (see Configure Kerberos Constrained Delegation (Optional) on page 2288). Use of explicit credentials is mutually exclusive of delegation.

The users and service account(s) you will be using to connect to your Microsoft CA(s) from Keyfactor Command need some set of the following permissions on the CA, based on the configuration of authorization for the CA:

- Read
  To support CA synchronization
- Issue and Manage Certificates
  To support certificate revocation and key recovery
- Manage CA
  To support CRL publication following revocation
- Request Certificates
  To support certificate enrollment through Keyfactor Command

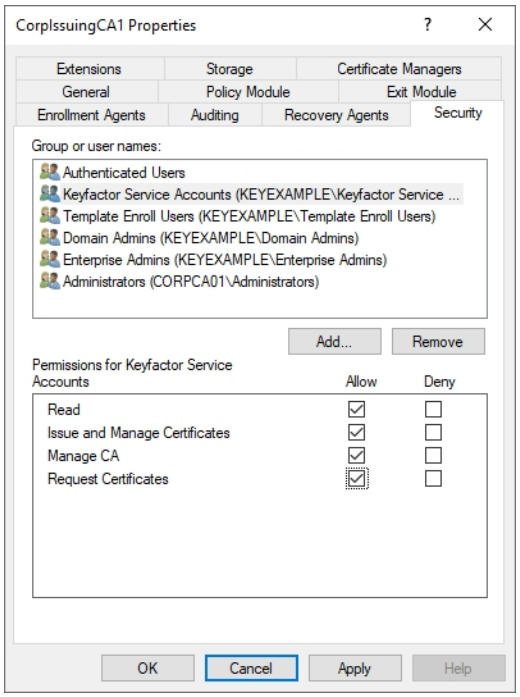

Figure 487: Microsoft CA Permissions

Table 767: Microsoft CA Permission Matrix provides information on what permissions are required based on possible authorization configurations.

Table 767: Microsoft CA Permission Matrix

	✔ Use Explicit Credentials	✘ Use Explicit Credentials ✔ Delegate Management ✔ Delegate Enrollment	✘ Use Explicit Credentials ✘ Delegate Management ✔ Delegate Enrollment	✘ Use Explicit Credentials ✔ Delegate Management ✘ Delegate Enrollment	✘ Use Explicit Credentials ✘ Delegate Management ✘ Delegate Enrollment
Explicit CA-Specific User	Read Issue & Manage Certificates Manage CA Request Certificates	n/a	n/a	n/a	n/a
Keyfactor	None	Read	Read	Read	Read

	✔ Use Explicit Credentials	✘ Use Explicit Credentials ✔ Delegate Management ✔ Delegate Enrollment	✘ Use Explicit Credentials ✘ Delegate Management ✔ Delegate Enrollment	✘ Use Explicit Credentials ✔ Delegate Management ✘ Delegate Enrollment	✘ Use Explicit Credentials ✘ Delegate Management ✘ Delegate Enrollment
Command Service Account		Request Certificates[1]	Request Certificates[2]	Request Certificates[3]	Request Certificates[4]
Keyfactor Command Application Pool Account	None	Read Issue & Manage Certificates Manage CA Request Certificates[5]	Read Issue & Manage Certificates Manage CA Request Certificates[6]	Read Manage CA Request Certificates	Read Issue & Manage Certificates Manage CA Request Certificates
Individual Users	None	Read Issue & Manage Certificates Request Certificates	Read Request Certificates	Read Issue & Manage Certificates	None

In the management console for each CA that Keyfactor Command will be interacting with, open the properties for the CA and grant the users and service account(s) for Keyfactor Command the appropriate permissions for your environment before continuing.

Tip: In order to support PFX and CSR enrollment through the Management Portal, the user initiating the enrollment in the Management Portal must be granted "Request Certificates" permission in the CA if enroll-

[1]To support certificate enrollment through Keyfactor Command that occurs in an automated fashion (e.g. certificate renewals initiated by the expiration alert renewal handler).
[2]To support certificate enrollment through Keyfactor Command that occurs in an automated fashion (e.g. certificate renewals initiated by the expiration alert renewal handler).
[3]To support certificate enrollment through Keyfactor Command that occurs in an automated fashion (e.g. certificate renewals initiated by the expiration alert renewal handler).
[4]To support certificate enrollment through Keyfactor Command that occurs in an automated fashion (e.g. certificate renewals initiated by the expiration alert renewal handler).
[5]To support tests of certificate enrollment through Keyfactor Command that occurs in an automated fashion (e.g. certificate renewals initiated by the expiration alert renewal handler).
[6]To support tests of certificate enrollment through Keyfactor Command that occurs in an automated fashion (e.g. certificate renewals initiated by the expiration alert renewal handler).

ment delegation is enabled. In many environments, all Authenticated Users are granted this permission, allowing the Management Portal users to inherit the permission.

EJBCA CAs

Management (e.g. revocation, certificate synchronization) and enrollment requests to an EJBCA CA are made in the context of the end entity associated with the client certificate selected in each CA configuration in the Keyfactor Command Management Portal to provide authentication to the EJBCA CA (see Acquire a Client Certificate for EJBCA CA Authentication on page 2307). The access rule created or used for this needs to grant sufficient permissions to allow the end entity to synchronize certificates. For full functionality, it needs the following permissions:

- /administrator/

  To support Keyfactor Command making API requests to the EJBCA CA
- /ca/*[your_ca_name]*/

  To support Keyfactor Command access to your CA
- /ca_functionality/create_certificate/

  To support certificate enrollment through Keyfactor Command
- /ca_functionality/create_crl/

  To support CRL publication following revocation
- /ca_functionality/view_ca/

  To support retrieval of CA information
- /ca_functionality/view_certificate/

  To support CA synchronization
- /ca_functionality/view_certificate_profiles/

  To support template import
- /endentityprofilesrules/*[your_end_entity_profile_name]*/create_end_entity/

  To support creation of end entities (a new end entity is created for each Keyfactor Command certificate enrollment unless the *Enforce Unique DN* option is enabled and the new certificate's DN matches that of an existing certificate)
- /endentityprofilesrules/*[your_end_entity_profile_name]*/edit_end_entity/

  To support certificate enrollment with the *Enforce Unique DN* option through Keyfactor Command and certificate renewal through Keyfactor Command
- /endentityprofilesrules/*[your_end_entity_profile_name]*/revoke_end_entity/

  To support certificate revocation through Keyfactor Command
- /endentityprofilesrules/*[your_end_entity_profile_name]*/view_end_entity/

  To support certificate enrollment through Keyfactor Command
- /ra_functionality/create_end_entity

To support creation of end entities (a new end entity is created for each Keyfactor Command certificate enrollment unless the *Enforce Unique DN* option is enabled and the new certificate's DN matches that of an existing certificate)

- /ra_functionality/edit_end_entity

  To support certificate enrollment with the *Enforce Unique DN* option through Keyfactor Command and certificate renewal through Keyfactor Command

- /ra_functionality/revoke_end_entity

  To support certificate revocation through Keyfactor Command

- /ra_functionality/view_end_entity

  To support certificate enrollment through Keyfactor Command

- /system_functionality/view_administrator_privileges

  To support overall functionality

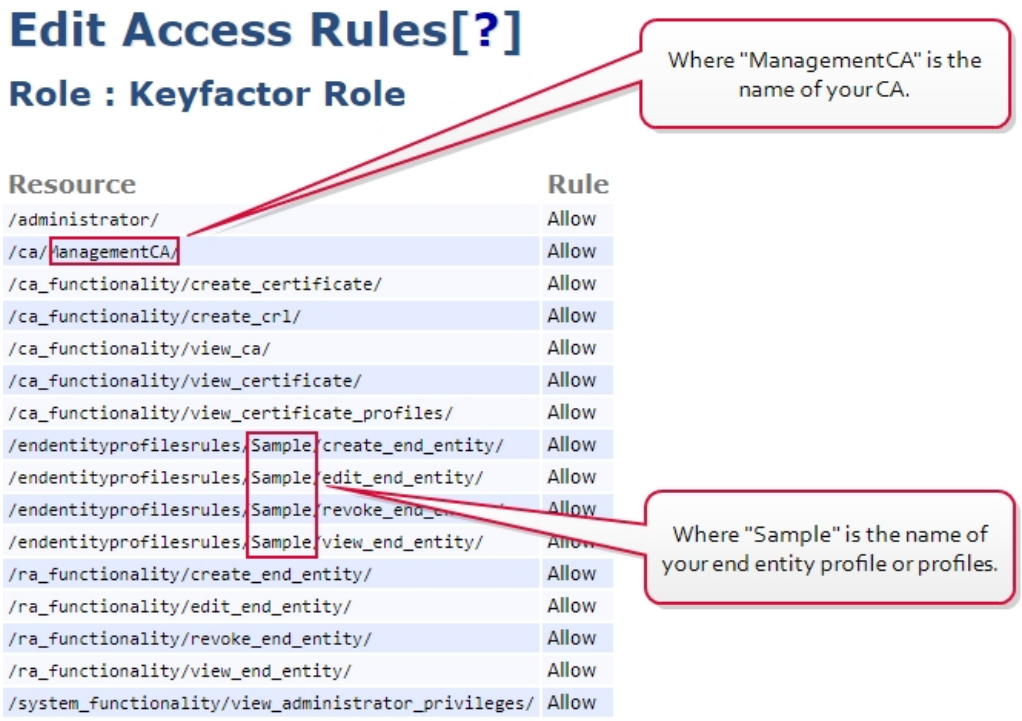

Figure 488: EJBCA Access Permissions

You may either create a new access rule that limits access to just these required permissions, or use an existing access rule. In either case, you need to add the certificate used to authenticate Keyfactor Command to the EJBCA CA as a member of that access rule.

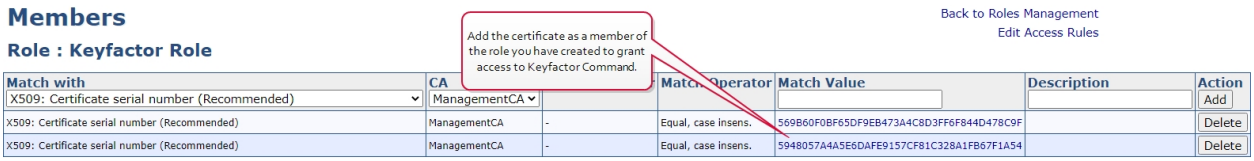

Figure 489: Add Client Certificate as Member of EJBCA Access Rule

Enable and Start the Keyfactor Command Service

The Keyfactor Command Service runs on the Keyfactor Command server hosting the Services role and controls database synchronization, among other jobs. During the Keyfactor Command configuration process you configured the service account under which the Keyfactor Command Service will run and may have configured the service to start automatically at server boot time (see Configure: Service on page 2267).

Tip: As of Keyfactor Command version 10.1 the Keyfactor Command Service can be installed on every server that Keyfactor Command is installed on, for instance in a high availability scenario. This will allow the service to check out jobs via a locking mechanism which will enforce that any jobs are running on only one service at a time. There is a new *CMSTimerService.exe.config* timeout setting for the service locking mechanism `<add key="Keyfactor.TimerJobs.LockTimeout" value="5000" />` which is the lock timeout. It's the number of ms Keyfactor Command will wait to acquire a lock. By default Keyfactor Command will attempt to get a lock for 5 secs and if unsuccessful, an error will be thrown.

To begin the CA synchronization, you just need to start the service (if it hasn't started automatically):

1. On the Keyfactor Command server hosting the Services role, open the Services MMC.
2. In the Services MMC confirm that the Keyfactor Command Service is set to a Startup Type of Automatic (if desired). If the service is not running, click the green arrow to start it.

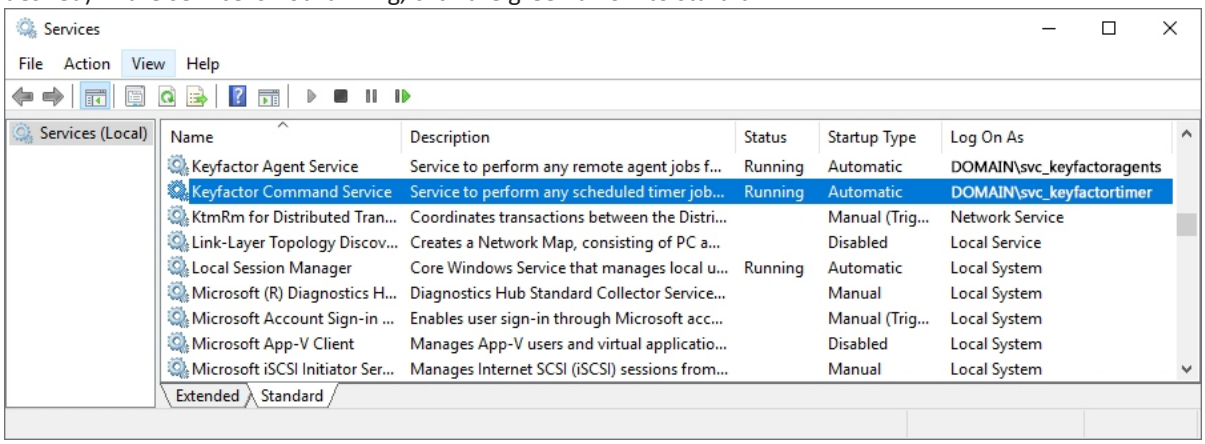

Figure 490: Keyfactor Command Service

The CA(s) will begin to synchronize when the first scheduled scan time is reached. Scans scheduled at intervals match to clock times, so a scan set at an interval of 15 minutes will run at 6:00, 6:15, 6:30, 6:45, etc. You can check the Keyfactor Command timer service log file on the Keyfactor Command Services server to confirm that

synchronization is operating as expected. You can also use the Certificate Search feature in the Keyfactor Command Management Portal to confirm the certificates are appearing in the Keyfactor Command database. That database synchronization begins with the oldest certificates in the CA database, which may be expired or revoked. Be sure to toggle the Include Revoked and Include Expired options, see Include Expired and Revoked Certificates in Certificate Search below, when checking to see if synchronization is working. See Certificate Search Page on page 31 in the *Keyfactor Command Reference Guide* for information on using the search.

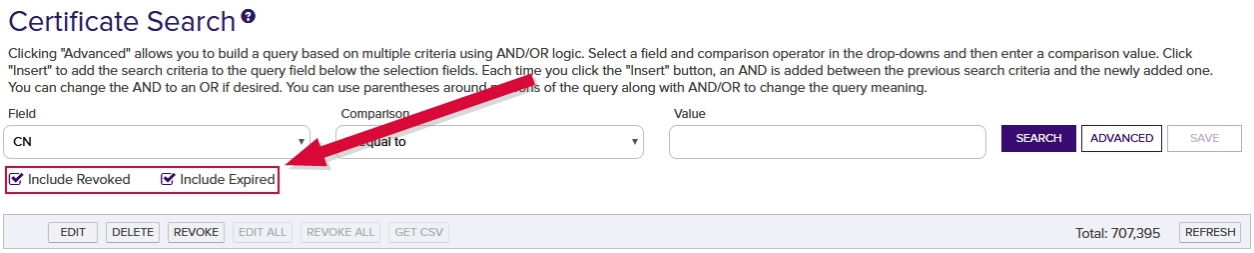

Figure 491: Include Expired and Revoked Certificates in Certificate Search

4.4.4.4 Create or Identify Certificate Templates for Enrollment

This step only needs to be completed if your Keyfactor Command license includes certificate enrollment and you plan to use this feature.

> **Note:** Keyfactor Command and this documentation use the term *template* generically to refer to Microsoft certificate templates and EJBCA certificate templates. EJBCA templates are built from the EJBCA end entity profile and certificate profile and named using a naming scheme of *<end entity profile name>_<certificate profile name>* and *<end entity profile name>* (*<certificate profile name>*) for the template name and template display name.

The enrollment function in the Keyfactor Command Management Portal is generally used by administrators to request certificates for use on servers, network devices, and similar equipment. There's a good chance that certificate templates for these purposes already exist in your environment. To prepare for the Keyfactor Command installation, you need to gather a list of the CAs that will be used to issue certificates through the Keyfactor Command Management Portal and a list of the *template names* (vs template display names) of the templates that will be used for this (Microsoft CAs) or certificate profiles and end entity profiles (EJBCA CAs). If any new templates or profiles need to be created for this purpose, they should be created before completing the Keyfactor Command post-installation steps.

For Microsoft CAs, the security settings on your existing templates may need to be modified to allow users to enroll for certificates using them through the Keyfactor Command Management Portal, depending on how the templates have been used previously. For CAs in the local forest (the forest in which Keyfactor Command is installed) and forests in a two-way trust with the local forest, enrollment through the Keyfactor Command Management Portal is often done in the context of the user logged into the portal. This differs from enrolling for a certificate through the Microsoft certificates MMC, where requests for computer certificates (such as web server certificates) are done in the context of the machine account from which the certificate is requested, not the user account, and thus the machine account needs permissions, not the user. When using the Keyfactor Command Management Portal, each of the users who will use one of the enrollment functions needs **Read** and **Enroll** permis-

sions on the templates they will be using through the portal (see Grant the Keyfactor Command Users and Service Account(s) Permissions on the CAs on page 2308 for more details).

Tip: Enrollment through the Keyfactor Command Management Portal against remote Microsoft CAs (CAs in a forest with either no trust with the forest in which Keyfactor Command is installed or a one-way trust) are done in the context of the service account configured on the Management Portal CA record for *Explicit Credentials* (see Create Active Directory Service Accounts for Keyfactor Command on page 2229).

The Keyfactor Command Management Portal offers the option of using a different set of CAs and templates for each of the two different enrollment methods—PFX and CSR. As you collect your list of CAs and templates, you will need to decide whether you want to use the same CAs and templates for both types of enrollment or whether each type of enrollment will have a unique list of CAs and templates.

The list of templates used for enrollment in the Keyfactor Command Management Portal is configured through the Keyfactor Command Management Portal template management. Although in previous releases of Keyfactor Command, the templates and CAs for enrollment were configured during installation, this is now done as a post-install step in the Management Portal. See Certificate Authorities on page 307 and Certificate Template Operations on page 334 in the *Keyfactor Command Reference Guide*.

4.4.4.5 Configure Renewal Handler Permission

The expiration renewal event handler allows you to execute a certificate renewal automatically for each expiring certificate that is found in a supported certificate store for each expiration alert when the alert task is triggered by the execution of the expiration alerts. In order for the renewal handler to execute successfully, the Active Directory service account under which the Keyfactor Command Service runs must have select permissions in the Keyfactor Command Management Portal. In addition, if you wish to test the execution of expiration alerts with renewal handlers and your IIS application pool runs in the context of a different Active Directory service account than the Keyfactor Command Service, the Active Directory service account for the IIS application pool must also be granted these permissions.

Note: If your Microsoft CA has been configured with the *Use Explicit Credentials* option, the permissions described here need to be granted to the user specified by the *Use Explicit Credentials* option, not either of the above-referenced service accounts.
If you're using an EJBCA CA, no further permissions need to be granted and this step may be skipped.

If you don’t plan to use the expiration renewal handler, you can skip this step.

To configure permissions for the service account(s) to support use of the expiration renewal handler:

1. In the Keyfactor Command Management Portal, browse to *System Settings Icon*  *> Security Roles & Identities*.

2. On the Security Roles and Identities page on the Security Roles tab, click **Add** to create a new role to be used just to grant permissions to the service account(s) to support use of the expiration renewal handler.

3. On the Details tab, give it an appropriate name and description to reflect this usage.

4. On the Global Permissions tab, click the **Enroll PFX** toggle for *Certificate Enrollment* to enable it, click the **Read** and **Schedule** toggles for *Certificate Store Management* to enable them, and click the **Read** toggle for *Management Portal* to disable it, if enabled.

5. Click **Save** to save the role.

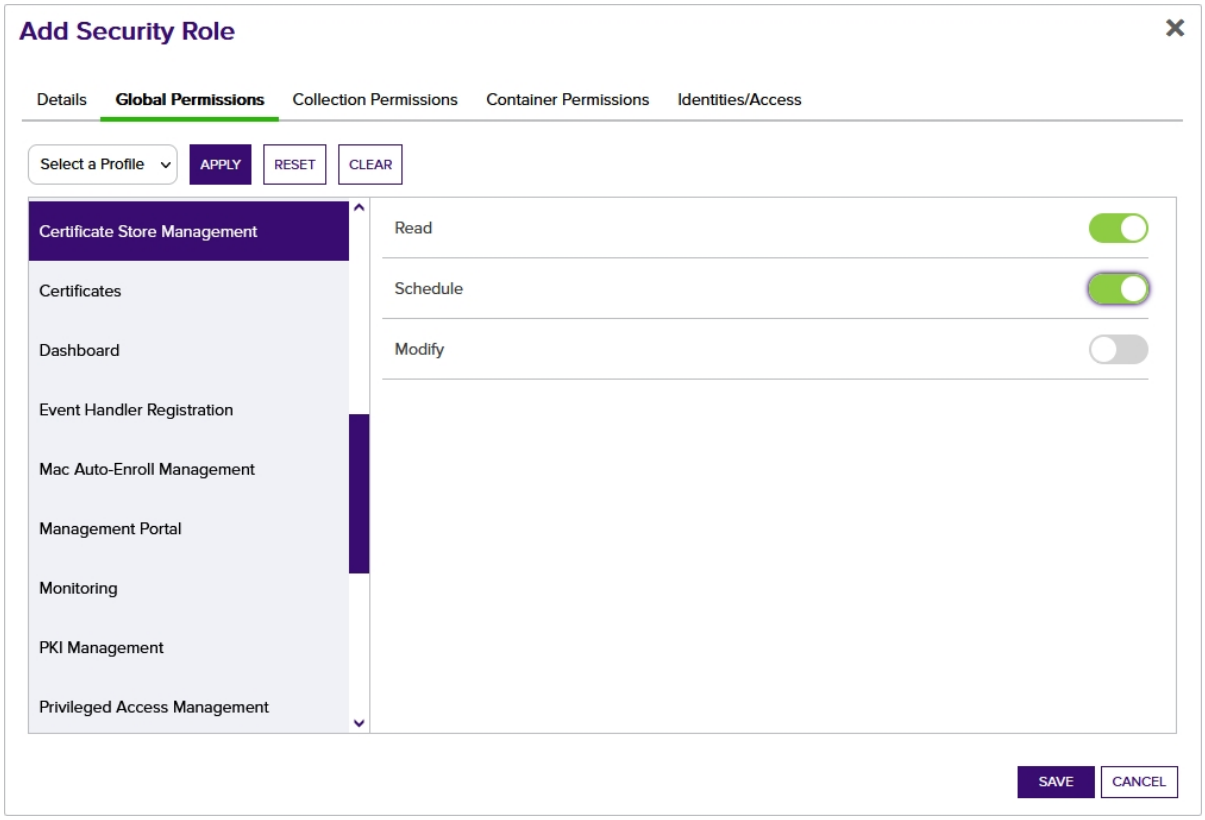

Figure 492: Configure Expiration Renewal Handler

6. On the Security Roles and Identities page on the Security Identities tab, click **Add** to add a new security identity.

7. In the Security Identities dialog, enter the Active Directory user name of the service account under which the Keyfactor Command Service runs using DOMAIN\username format and click **Save**. If the account resolves correctly, the new identity will be saved and the dialog will close.

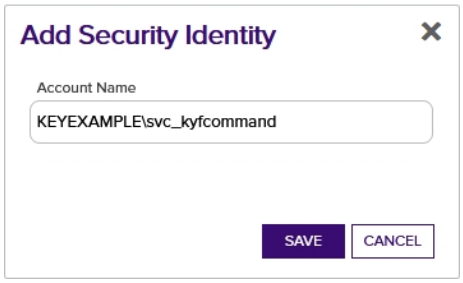

Figure 493: Configure Expiration Renewal Handler: Add New Identity

8. If your IIS application pool runs as a different Active Directory service account from that used for the Keyfactor Command Service, repeat steps four and five for the IIS application pool service account.

9. In the Security Identity Editor section of the page, double-click the Keyfactor Command Service identity in the identity grid, right-click the row in the identity grid and choose **Edit Roles** from the right-click menu, or highlight the Keyfactor Command Service identity in the identity grid and click **Edit Roles** at the top of the identity grid.

10. In the Roles dialog, select the role you created for the expiration renewal handler in the Available Roles list and use the right arrow to move the role to the Current Roles list. Click **Save** to assign the role to the identity.

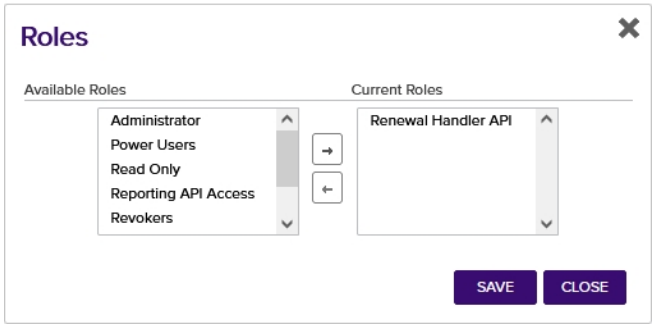

Figure 494: Configure Expiration Renewal Handler: Assign Role to Identity

11. If your IIS application pool runs as a different Active Directory service account from that used for the Keyfactor Command Service, repeat steps seven and eight for the IIS application pool service account.

4.4.4.6 Create a Certificate Template for Mac Auto-Enrollment

This step only needs to be completed if your Keyfactor Command license includes Mac auto-enrollment and you plan to use this feature.

To create the certificate template that will be used for Mac auto-enrollment:

1. On the CA that will issue the Mac auto-enrollment certificates, open the Certification Authority management tool.

2. In the Certification Authority management tool, drill down to locate the Certificate Templates folder. Right-click the **Certificate Templates** folder and choose **Manage**. This will open the Certificate Templates Console.

3. In the Certificate Templates Console, right-click the User template and choose **Duplicate Template**.

4. If prompted with a Duplicate Template dialog (some versions of Windows), choose Windows Server 2003 Enterprise and click **OK**.

5. General Tab: In the Properties of New Template dialog on the General tab, enter **Mac Auto-Enrollment** (or an alternate name of your choosing) in the **Template display name** field. The **Template name** will be auto-populated based on the text you enter in the **Template display name**. Select a **Validity period** for the certificate that's appropriate for your environment.

6. Extensions Tab: If you plan to use the certificates to authenticate to enterprise systems, you will need to ensure that **Client Authentication** is set as the only application policy in the certificate. To do this, in the **Extensions included in this template** section of the Extensions tab, highlight **Application Policies** and click the **Edit**... button. In the Edit Application Policies Extensions dialog, remove the **Encrypting File System** and **Secure Email** policies and click **OK**.

7. Security Tab: In the Properties of New Template dialog on the Security tab, add the Active Directory group of users who will be allowed to auto-enroll from Macs and grant this group **Read**, **Enroll**, and **Autoenroll** permissions on the template.

8. Click **OK** to save the new template.

9. Back in the Certification Authority management tool, right-click the **Certificate Templates** folder and choose **New->Certificate Template to Issue**. Select the **Mac Auto-Enrollment** template from the list presented and click **OK**.

4.5 Keyfactor CA Policy Module

The Keyfactor CA Policy Module includes four certificate authority policy handlers that can be used to alter or restrict the functionality of a Microsoft certificate authority. The policy handlers are installed on the Microsoft CA and enabled through the Microsoft CA properties page. The available policy handlers are:

RFC 2818 Policy Handler

Automate inclusion of a DNS SAN matching the CN of the requested certificate in certificate enrollments for a defined set of CA templates.

SAN Attribute Policy Handler

Allow the addition of SANs not included in the CSR when making a CSR enrollment request. The added SANs will overwrite any existing SANs in the CSR. This functionality is the same as that seen with the Microsoft default policy module for the CA as a whole when the CA EDITF_ATTRIBUTESUBJECTALTNAME2 flag is set except the SAN Attribute Policy Handler provides the ability to control SAN addition on a template-by-template basis without the need to enable the Microsoft CA EDITF_ATTRIBUTESUBJECTALTNAME2 flag.

vSCEP™ Policy Handler

Allow secure control of on-device key generation during certificate enrollment for iOS and Mac devices.

Whitelist Policy Handler

Enforce that certificate requests for a given template or templates can only be initiated from a given computer or set of computers.

Important: If you're upgrading from a previous version of the Keyfactor CA Policy Module, refer to the *Keyfactor Command Upgrade Overview* for important upgrade instructions and a required upgrade script. Newer versions of Keyfactor CA Policy Module **cannot** be installed over the top of existing Keyfactor CA Policy Module installations to complete an upgrade.

4.5.1 System Requirements

The Keyfactor CA Policy Module is supported on Microsoft certificate authorities running on Windows Server 2016 or higher. It interoperates with Keyfactor Command versions 9.0 or greater.

The policy module requires the Microsoft .NET **Desktop** Runtime version 6.0 (x64). Version 6.0 is available for download from Microsoft:

https://dotnet.microsoft.com/download/dotnet/6.0/runtime

At the above link, this would be the **Download x64** option under the "Run desktop apps" heading.

You can use the following PowerShell command to check the .NET core version(s) installed on a server (if any):

```
dotnet --list-runtimes
```

Output from this command will look something like this if you have the correct 6.0 x64 version of the .NET Desktop Runtime installed (notice the paths are in C:\Program Files, not C:\Program Files (x86), indicating this is the x64 version):

```
Microsoft.NETCore.App 6.0.11 [C:\Program Files\dotnet\shared\Microsoft.NETCore.App]
Microsoft.WindowsDesktop.App 6.0.11 [C:\Program
Files\dotnet\shared\Microsoft.WindowsDesktop.App]
```

Important: If you're upgrading from a previous version of the Keyfactor CA Policy Module, refer to the *Keyfactor Command Upgrade Overview* for important upgrade instructions and a required upgrade script. Newer versions of Keyfactor CA Policy Module **cannot** be installed over the top of existing Keyfactor CA Policy Module installations to complete an upgrade.

4.5.2 Preparing for the Keyfactor CA Policy Module

The preparation steps necessary for the Keyfactor CA Policy Module vary depending on the policy handler(s) you intend to use.

Important: If you're upgrading from a previous version of the Keyfactor CA Policy Module, refer to the *Keyfactor Command Upgrade Overview* for important upgrade instructions and a required upgrade script. Newer versions of Keyfactor CA Policy Module **cannot** be installed over the top of existing Keyfactor CA Policy Module installations to complete an upgrade.

The policy handlers have the following preparation requirements:

RFC 2818 Policy Handler

During the configuration of the RFC 2818 Policy Handler, you will need to define the list of Microsoft certificate templates that will automatically be assigned a DNS SAN matching the certificate's CN when a certificate enrollment request reaches the CA. These templates are configured by selecting them from a list. You will need to have this list of templates ready.

SAN Attribute Policy Handler

During the configuration of the SAN Attribute Policy Handler, you will need to define the list of Microsoft certificate templates that will allow certificate enrollment requests via CSR to submit SANs outside of the CSR for inclusion in the final certificate, replacing any SANs originally in the CSR. These templates are configured by selecting them from a list. You will need to have this list of templates ready.

vSCEP™ Policy Handler

During the configuration of the vSCEP™ Policy Handler, you will need to enter the URL to the vSCEP service on your Keyfactor Command server and the username and password of a service account that the policy handler will use to make requests to the vSCEP API on the Keyfactor Command server. The user you enter here needs to be a member of the group you configure for *Allowed Users/Groups* on the vSCEP Service tab in the Keyfactor Command configuration wizard (see vSCEP Services Tab on page 2272). The service account needs to be created in Active Directory prior to installation of the Keyfactor CA Policy Module software, and the person installing the Keyfactor CA Policy Module software needs to know the service account domain, username and password.

Whitelist Policy Handler

During the configuration of the SAN Attribute Policy Handler, you will need to define the list of Microsoft certificate templates that will be gated by the handler and the list of machines that will be allowed to use these templates. Any templates you include will be available for enrollment only from machines you include in the allowed list. The purpose of this handler is to force all enrollments to be made from the Keyfactor Command server(s), so the list of machines should include your Keyfactor Command server(s). The templates for this policy handler are configured by typing in their certificate *template name* (short name), so you will need an exact list of the template names.

In addition, you will need to have your Keyfactor product license available for upload into the policy module once installed to activate it.

4.5.3 Installing the Keyfactor CA Policy Module Handlers

These steps only need to be completed if your Keyfactor Command license includes the Keyfactor CA Policy Module and you plan to use this feature and one or more of its policy handlers. Review the policy handlers to determine if one or more of them meets a need in your environment.

Important: For a CA Clustered solution, if the Keyfactor CA Policy Module is installed on a node then configured, then failed over to another node, this will corrupt the check point key. The module must be installed on BOTH nodes, configured on one node, then failed over to the other node.

The available policy handlers are:

RFC 2818 Policy Handler

Automate inclusion of a DNS SAN matching the CN of the requested certificate in certificate enrollments for a defined set of CA templates.

SAN Attribute Policy Handler

Allow the addition of SANs not included in the CSR when making a CSR enrollment request. The added SANs will overwrite any existing SANs in the CSR. This functionality is the same as that seen with the Microsoft default policy module for the CA as a whole when the CA EDITF_ATTRIBUTESUBJECTALTNAME2 flag is set except the SAN Attribute Policy Handler provides the ability to control SAN addition on a template-by-template basis without the need to enable the Microsoft CA EDITF_ATTRIBUTESUBJECTALTNAME2 flag.

Important: By default, Microsoft CAs do not support the addition of SANs not included in the CSR when making a request using a CSR enrollment method. To enable your CA to support requesting certificates with additional SANs, you must either install and configure the Keyfactor Command SAN Attribute Policy Handler on the CA(s) or enable the Microsoft CA EDITF_ATTRIBUTESUBJECTALTNAME2 flag. There are security risks inherent in enabling either of these options on your CA. Keyfactor recommends that you do not enable these options unless it is an absolute requirement. With the SAN Attribute Policy Handler, you can limit the risk by limiting the exposure to just selected templates. Keyfactor further recommends that you:

- Use the SAN Attribute Policy Handler only with templates that require CA manager approval so that a manager will be required to review the request and the added SANs before the certificate is issued.
- Use the SAN Attribute Policy Handler in conjunction with the Whitelist Policy Handler to limit requests for the selected templates to being initiated only by the Keyfactor Command server(s).
- Configure server level monitoring with a product such as Microsoft's System Center Operations Manager (SCOM) to provide alerts for any changes relating to the CA(s) configured with the SAN Attribute Policy Handler so that, for example, changes to the templates configured to support SAN addition do not go unnoticed.

vSCEP™ Policy Handler

Allow secure control of on-device key generation during certificate enrollment for iOS and Mac devices.

Whitelist Policy Handler

Enforce that certificate requests for a given template or templates can only be initiated from a given computer or set of computers.

Note: The following Windows update affects how certificate requests are built when sent to a Microsoft CA and may cause enrollments done outside Keyfactor Command against a Microsoft CA configured with the Whitelist Policy Handler to fail.
https://support.microsoft.com/en-us/topic/kb5014754-certificate-based-authentication-changes-on-windows-domain-controllers-ad2c23b0-15d8-4340-a468-4d4f3b188f16

The processing order of the handlers currently available in the Keyfactor CA Policy Module, when used together on the same machine, is significant for some handlers and not others. Specifically, the processing order is not significant for the vSCEP™ Policy Handler and Machine Whitelist Policy handler. These handlers may be placed anywhere within the list of handlers. However, the processing order does matter for the SAN Attribute Policy Handler and the RFC 2818 Policy Handler. When these two handlers are used together, the SAN Attribute Policy Handler must be placed on the list above the RFC 2818 Policy Handler to allow the SAN Attribute Policy Handler to be processed before the RFC 2818 Policy Handler. This is because the SAN Attribute Policy Handler removes any existing SANs on the enrollment request and replaces them with those specified in the request outside of the CSR—such as those entered in the optional SAN section on the CSR page of the Keyfactor Command Management Portal. This includes any SANs added by the RFC 2818 Policy Handler.

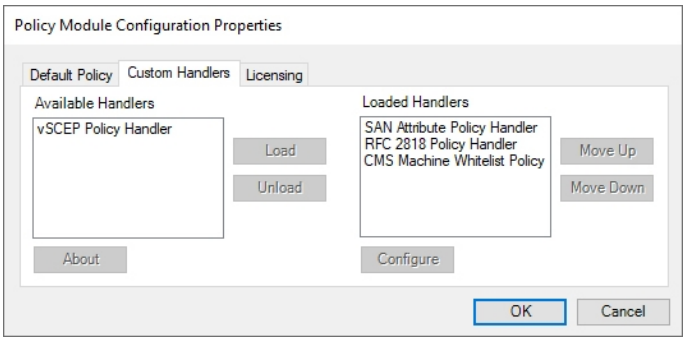

Figure 495: Keyfactor CA Policy Module Policy Module Handler Ordering

When the Keyfactor CA Policy Module is used, the policy module listed on the Default Policy tab of the Policy Module Configuration Properties dialog is run first when a request reaches the CA. This default policy might be the standard Windows default, as shown Figure 496: Default Policy Module, or it might be another non-built-in policy module, such as the Microsoft FIM CM Policy Module. After the default policy module runs, the Loaded Handlers on the Custom Handlers tab of the Policy Module Configuration Properties dialog are run in the order listed (top to bottom). After all the handlers have been run, the result (approved, denied, or marked as pending) is returned to the CA for processing.

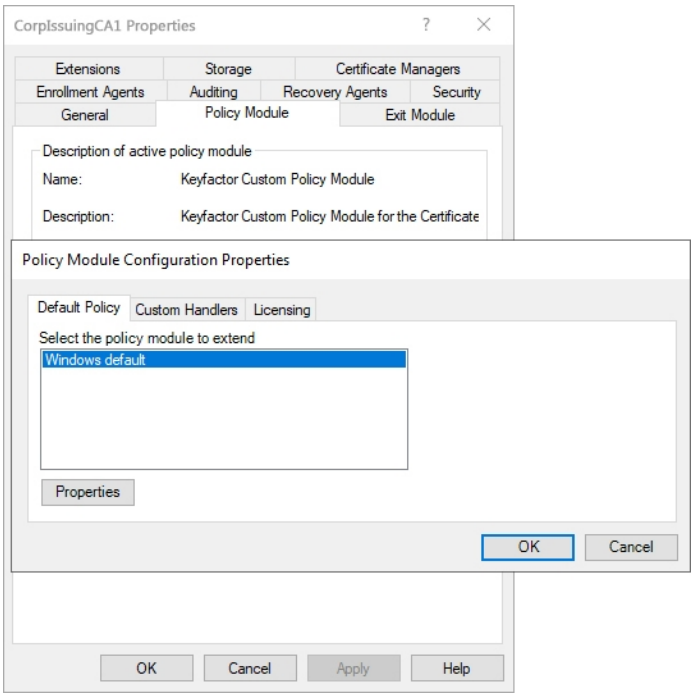

Figure 496: Default Policy Module

Tip: Once the installation is complete, the configuration options for the policy handlers can be found in the registry on the CA in the following paths (where CA_LOGICAL_NAME is the logical name of the local CA):

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services\CertSvc\Configuration\CA_
LOGICAL_NAME\PolicyModules\CMS_Custom.Policy\PolicyHandlers\RFC2818.PolicyHandler
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services\CertSvc\Configuration\CA_
LOGICAL_NAME\PolicyModules\CMS_
Custom.Policy\PolicyHandlers\SANAttribute.PolicyHandler
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services\CertSvc\Configuration\CA_
LOGICAL_NAME\PolicyModules\CMS_Custom.Policy\PolicyHandlers\vSCEP.PolicyHandler
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services\CertSvc\Configuration\CA_
LOGICAL_NAME\PolicyModules\CMS_
Custom.Policy\PolicyHandlers\CMSWhitelist.PolicyHandler
```

Warning: These registry keys should not be modified without advice from Keyfactor support.

4.5.3.1 Install the Keyfactor RFC 2818 Policy Handler

To begin the RFC 2818 Policy Handler installation, execute the KeyfactorCAModuleInstaller.msi file from the Keyfactor installation media and install as follows.

1. On the first installation page, click **Next** to begin the setup wizard.

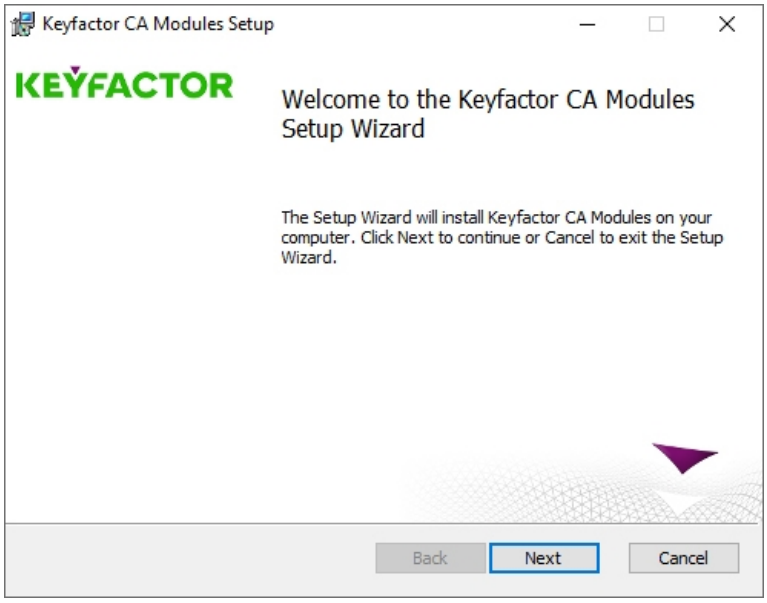

Figure 497: Install RFC 2818 Policy Handler: Begin Setup Wizard

2. On the next page, read and accept the license agreement and click **Next**.

3. On the next page, select the components to install. For the RFC 2818 Policy Handler, deselect all the components except the RFC 2818 Policy Handler component. If desired, you can highlight Keyfactor Custom Policy Module and click **Browse** to select an alternate installation location for the files. The default installation location is:

    C:\Program Files\Keyfactor\Keyfactor CA Modules

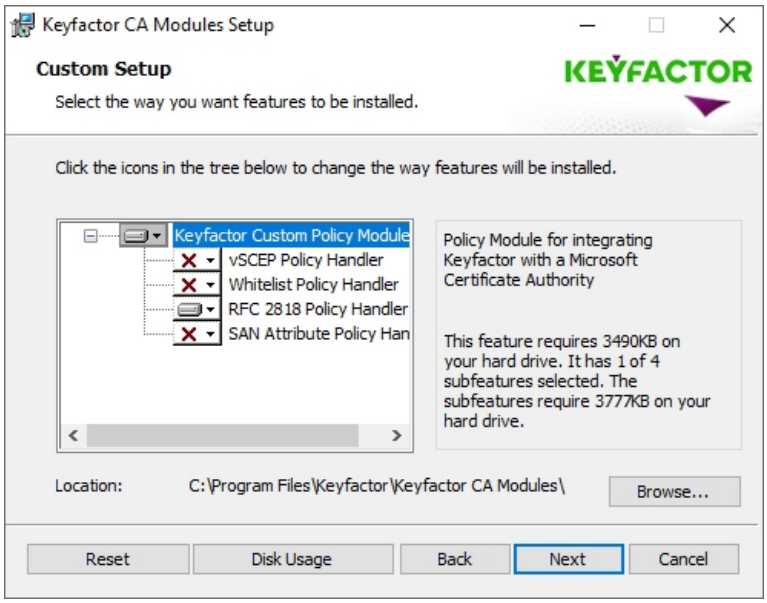

Figure 498: Install RFC 2818 Policy Handler: Select Components

4. On the next screen, click **Install**.

5. On the final installation wizard page, leave the "Launch the CA MMC snap-in now" box selected and click **Finish**. The Microsoft Certification Authority management tool should start automatically. This can take several seconds.

6. In the Certification Authority management tool, right-click the CA name at the top of the tree and choose **Properties**.

7. In the Properties dialog for the CA on the CA Policy Module tab, click **Select**, highlight the **Keyfactor Custom Policy Module** in the Set Active Policy Module dialog and click **OK**.

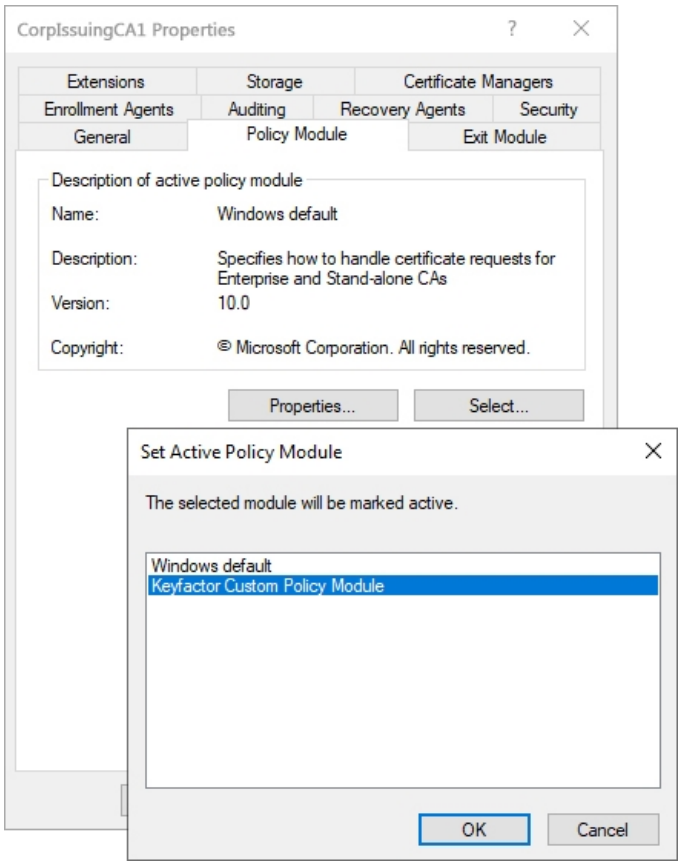

Figure 499: Enable the Keyfactor CA Policy Module

8. In the Properties dialog for the CA on the CA Policy Module tab, click **Properties**.

9. On the Licensing tab of the Policy Module Configuration Properties page, click **Upload License** and browse to locate the license file provided to you by Keyfactor. This file should have the extension CMSLICENSE.

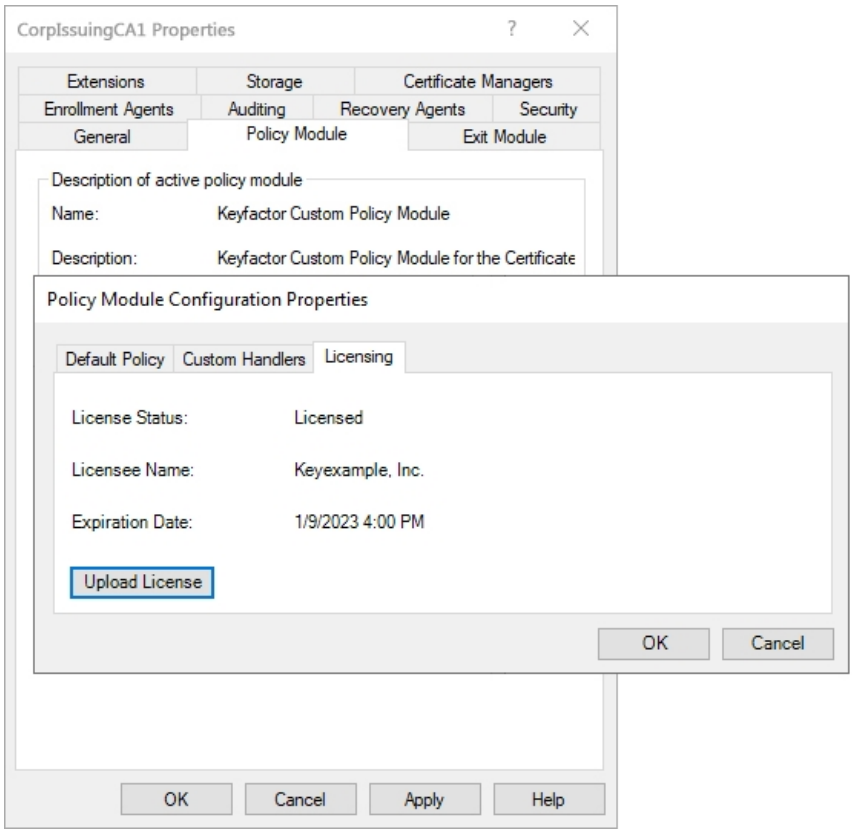

Figure 500: Upload the Keyfactor CA Policy Module License

10. On the Custom Handlers tab of the Policy Module Configuration Properties page, highlight the **RFC 2818 Policy Handler** under Loaded Handlers, click **Load** to move it over to the loaded handlers, and click **OK**.

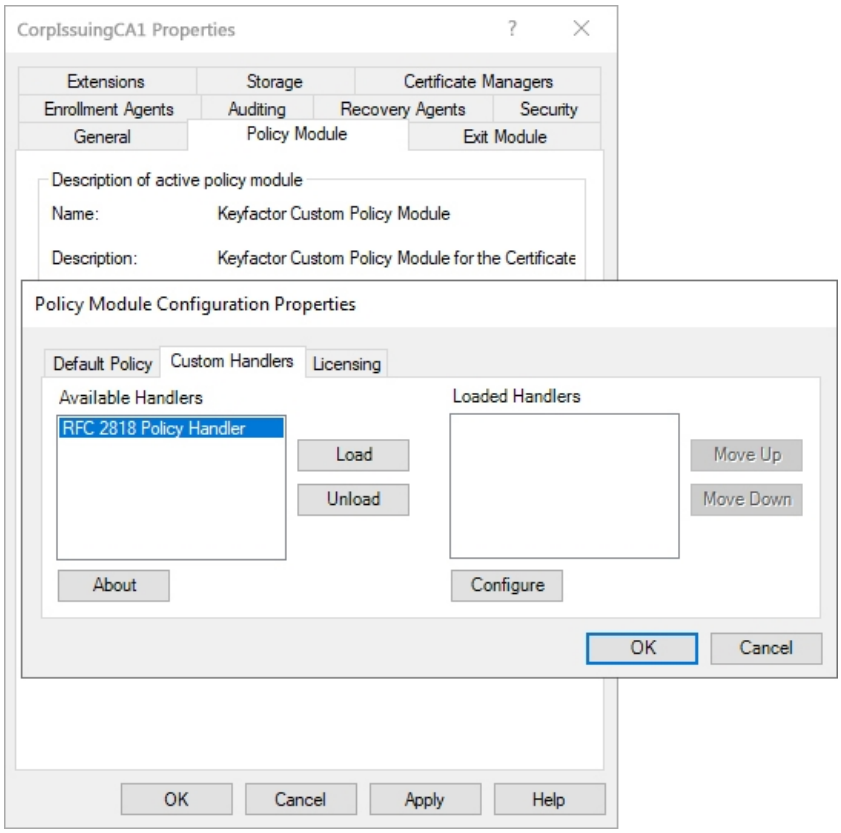

Figure 501: Enable the RFC 2818 Policy Handler

11. On the Custom Handlers tab of the Policy Module Configuration Properties page, highlight the RFC 2818 Policy Handler under Loaded Handlers and click **Configure**.

12. On RFC 2818 Policy Handler configuration dialog, select the templates that should be under management by the RFC 2818 policy handler and click **Add**. Certificate enrollments from any source made using the templates selected here on the configured CA will automatically be assigned a DNS SAN matching the certificate's CN.

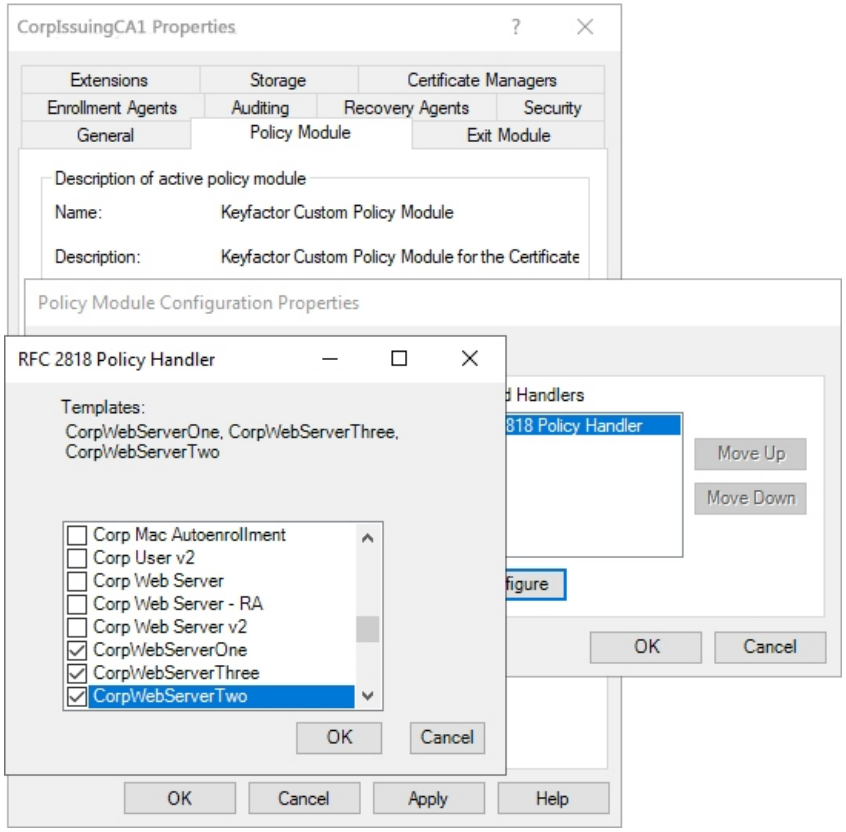

Figure 502: Add Templates for Management with the RFC 2818 Policy Handler

13. Click **OK** as many times as needed to close the configuration dialogs and save the configuration. You will be prompted to restart the CA services.

4.5.3.2 Install the Keyfactor SAN Attribute Policy Handler

To begin the SAN Attribute Policy Handler installation, execute the KeyfactorCAModuleInstaller.msi file from the Keyfactor installation media and install as follows.

1. On the first installation page, click **Next** to begin the setup wizard.

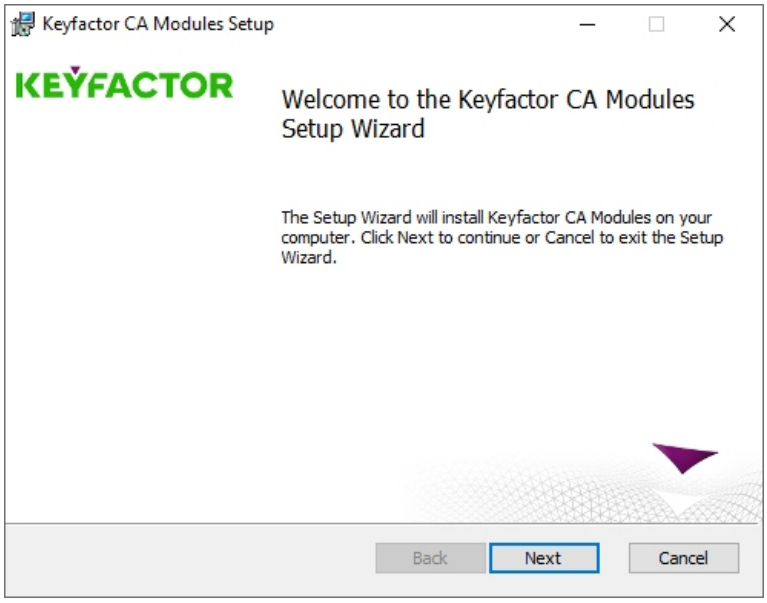

Figure 503: Install SAN Attribute Policy Handler: Begin Setup Wizard

2. On the next page, read and accept the license agreement and click **Next**.

3. On the next page, select the components to install. For the SAN Attribute Policy Handler, deselect all the components except the SAN Attribute Policy Handler component. If desired, you can highlight Keyfactor Custom Policy Module and click **Browse** to select an alternate installation location for the files. The default installation location is:

    C:\Program Files\Keyfactor\Keyfactor CA Modules

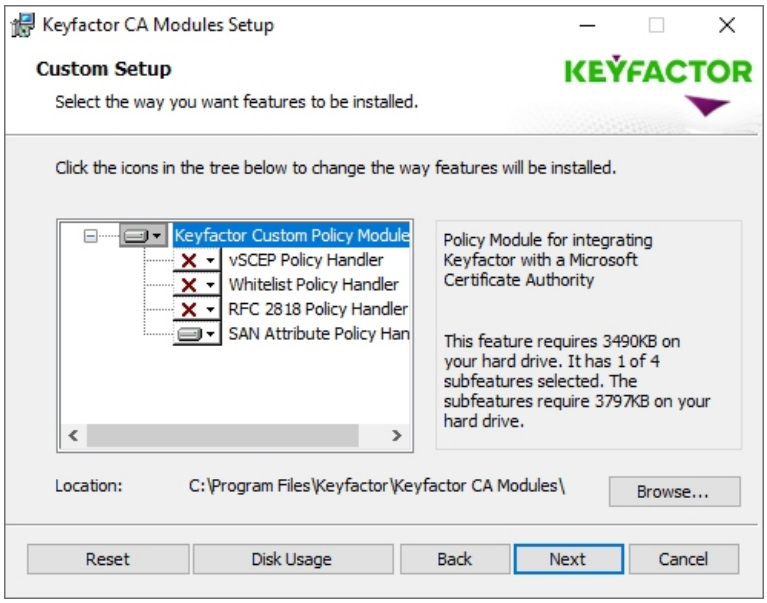

Figure 504: Install SAN Attribute Policy Handler: Select Components

4. On the next screen, click **Install**.

5. On the final installation wizard page, leave the "Launch the CA MMC snap-in now" box selected and click **Finish**. The Microsoft Certification Authority management tool should start automatically. This can take several seconds.

6. In the Certification Authority management tool, right-click the CA name at the top of the tree and choose **Properties**.

7. In the Properties dialog for the CA on the CA Policy Module tab, click **Select**, highlight the **Keyfactor Custom Policy Module** in the Set Active Policy Module dialog and click **OK**.

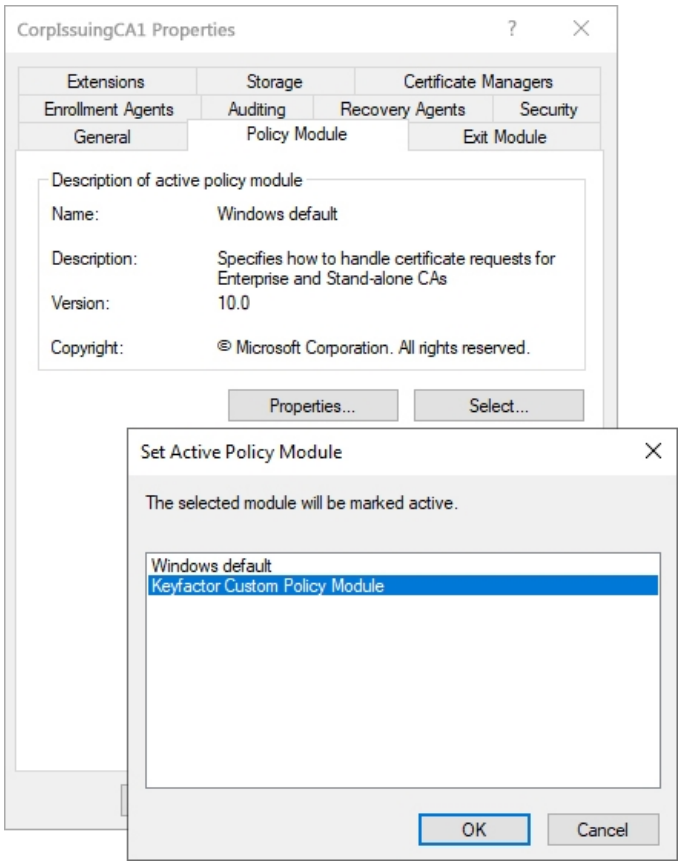

Figure 505: Enable the Keyfactor CA Policy Module

8. In the Properties dialog for the CA on the CA Policy Module tab, click **Properties**.

9. On the Licensing tab of the Policy Module Configuration Properties page, click **Upload License** and browse to locate the license file provided to you by Keyfactor. This file should have the extension CMSLICENSE.

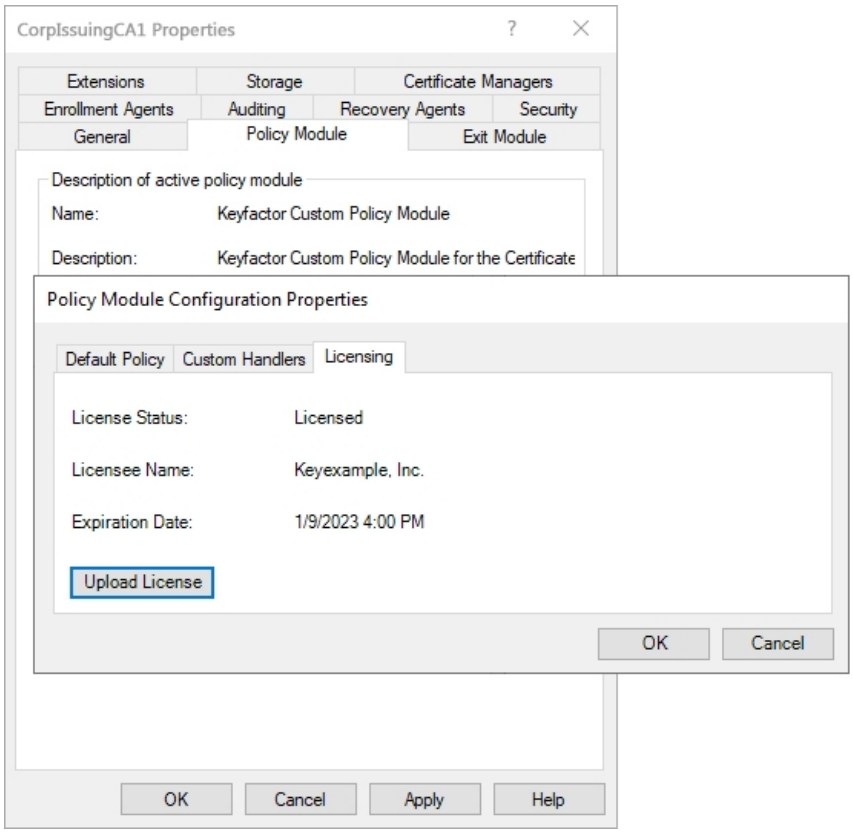

Figure 506: Upload the Keyfactor CA Policy Module License

10. On the Custom Handlers tab of the Policy Module Configuration Properties page, highlight the **SAN Attribute Policy Handler** under Loaded Handlers, click **Load** to move it over to the loaded handlers, and click **OK**.

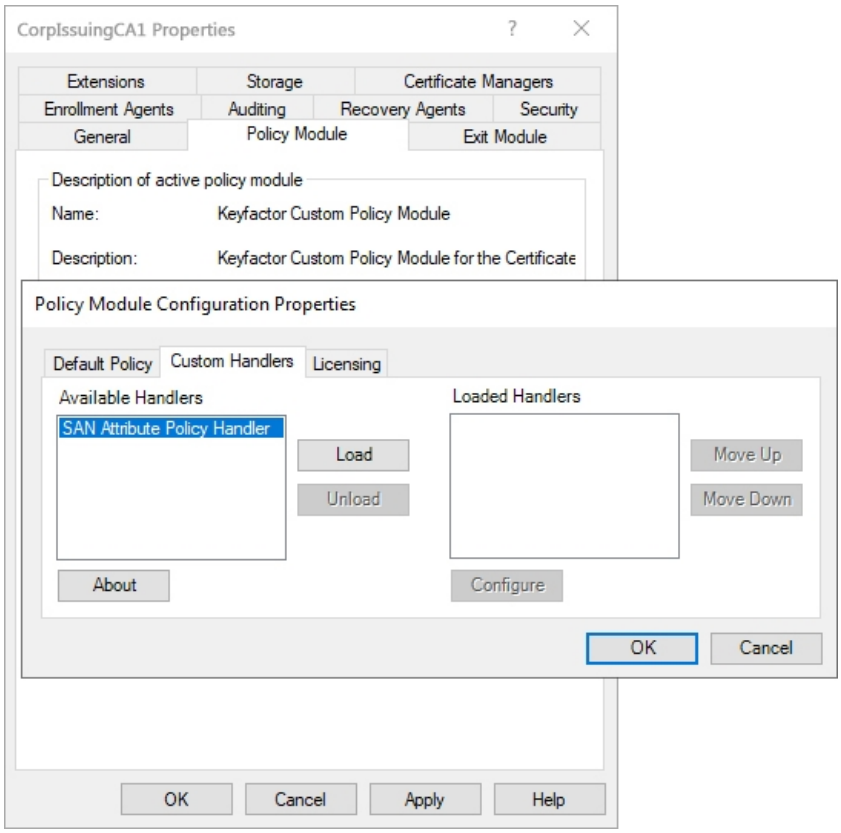

Figure 507: Enable the SAN Attribute Policy Handler

11. On the Custom Handlers tab of the Policy Module Configuration Properties page, highlight the SAN Attribute Policy Handler under Loaded Handlers and click **Configure**.

12. On SAN Attribute Policy Handler configuration dialog, select the templates that should be under management by the SAN Attribute policy handler and click **Add**. Certificate enrollments from any source made using the templates selected here on the configured CA and a CSR enrollment method will allow the addition of SANs not included in the CSR and control the SAN addition functionality on a template-by-template basis without the need to enable the Microsoft CA EDITF_ATTRIBUTESUBJECTALTNAME2 flag.

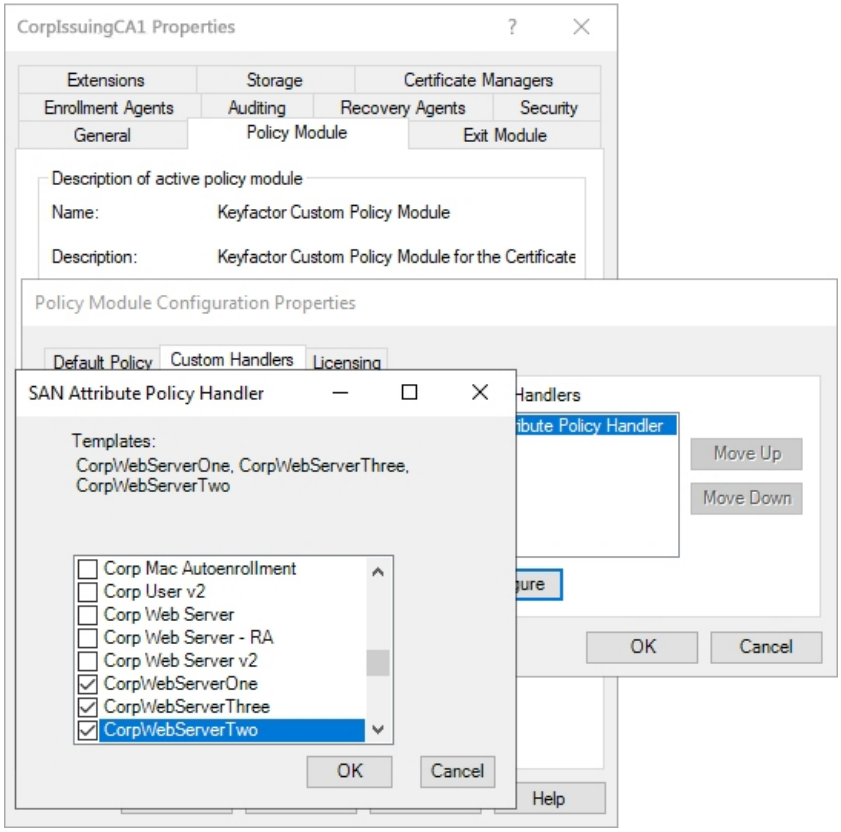

Figure 508: Add Templates for Management with the SAN Attribute Policy Handler

13. Click **OK** as many times as needed to close the configuration dialogs and save the configuration. You will be prompted to restart the CA services.

4.5.3.3 Install the Keyfactor vSCEP™ Policy Handler

To begin the vSCEP™ Policy Handler installation, execute the KeyfactorCAModuleInstaller.msi file from the Keyfactor installation media and install as follows.

1. On the first installation page, click **Next** to begin the setup wizard.

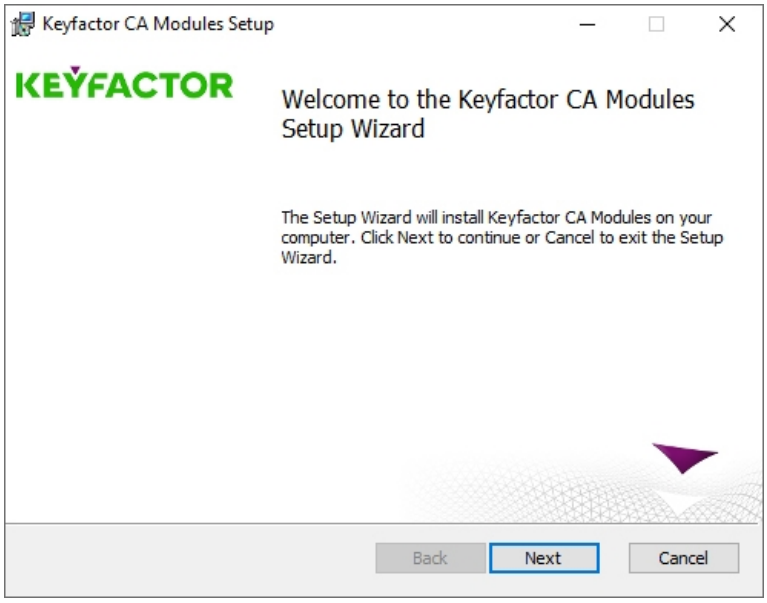

Figure 509: Install vSCEP Policy Handler: Begin Setup Wizard

2. On the next page, read and accept the license agreement and click **Next**.

3. On the next page, select the components to install. For the vSCEP™ Policy Handler, deselect all the components except the vSCEP™ Policy Handler component. If desired, you can highlight Keyfactor Custom Policy Module and click **Browse** to select an alternate installation location for the files. The default installation location is:

    C:\Program Files\Keyfactor\Keyfactor CA Modules

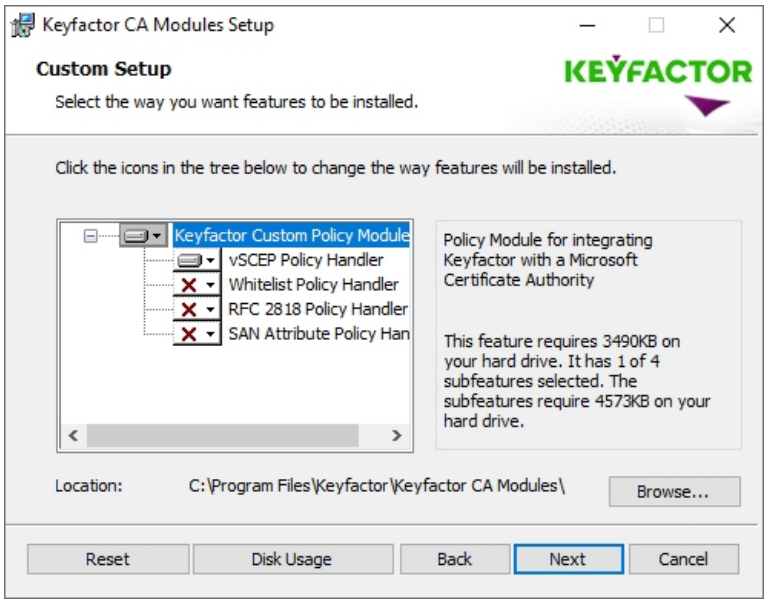

Figure 510: Install vSCEP Policy Handler: Select Components

4. On the next screen, click **Install**.

5. On the final installation wizard page, leave the "Launch the CA MMC snap-in now" box selected and click **Finish**. The Microsoft Certification Authority management tool should start automatically. This can take several seconds.

6. In the Certification Authority management tool, right-click the CA name at the top of the tree and choose **Properties**.

7. In the Properties dialog for the CA on the CA Policy Module tab, click **Select**, highlight the **Keyfactor Custom Policy Module** in the Set Active Policy Module dialog and click **OK**.

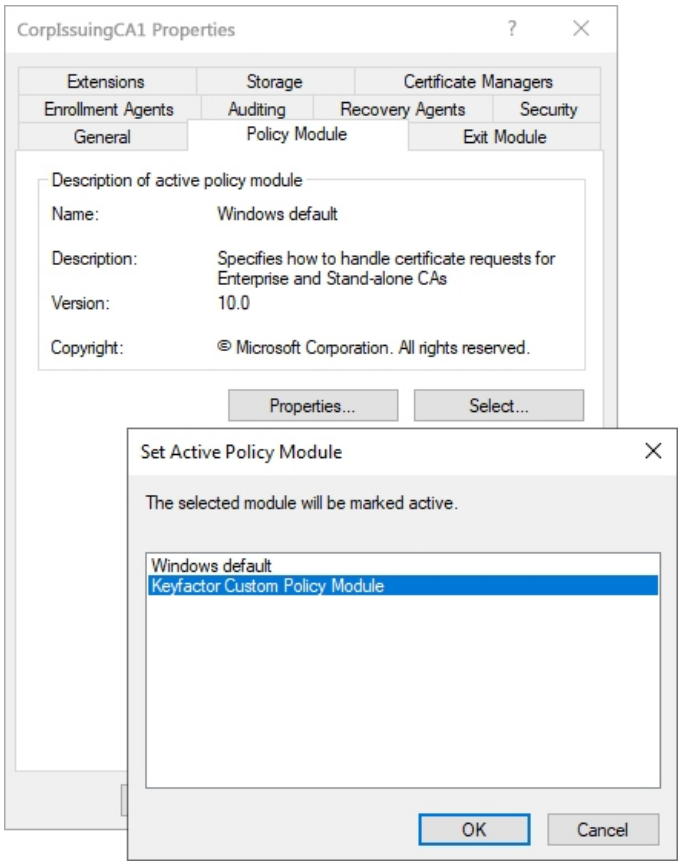

Figure 511: Enable the Keyfactor CA Policy Module

8. In the Properties dialog for the CA on the CA Policy Module tab, click **Properties**.

9. On the Licensing tab of the Policy Module Configuration Properties page, click **Upload License** and browse to locate the license file provided to you by Keyfactor. This file should have the extension CMSLICENSE.

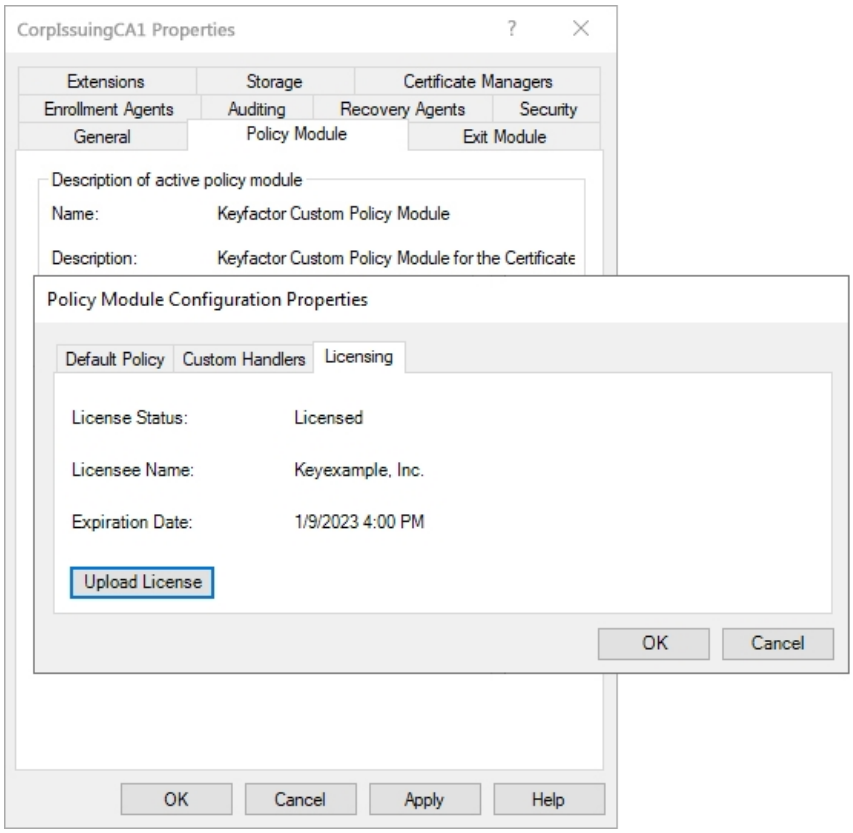

Figure 512: Upload the Keyfactor CA Policy Module License

10. On the Custom Handlers tab of the Policy Module Configuration Properties page, highlight the **vSCEP Policy Handler** on the list of available handlers, click **Load** to move it over to the loaded handlers, and click **OK**.

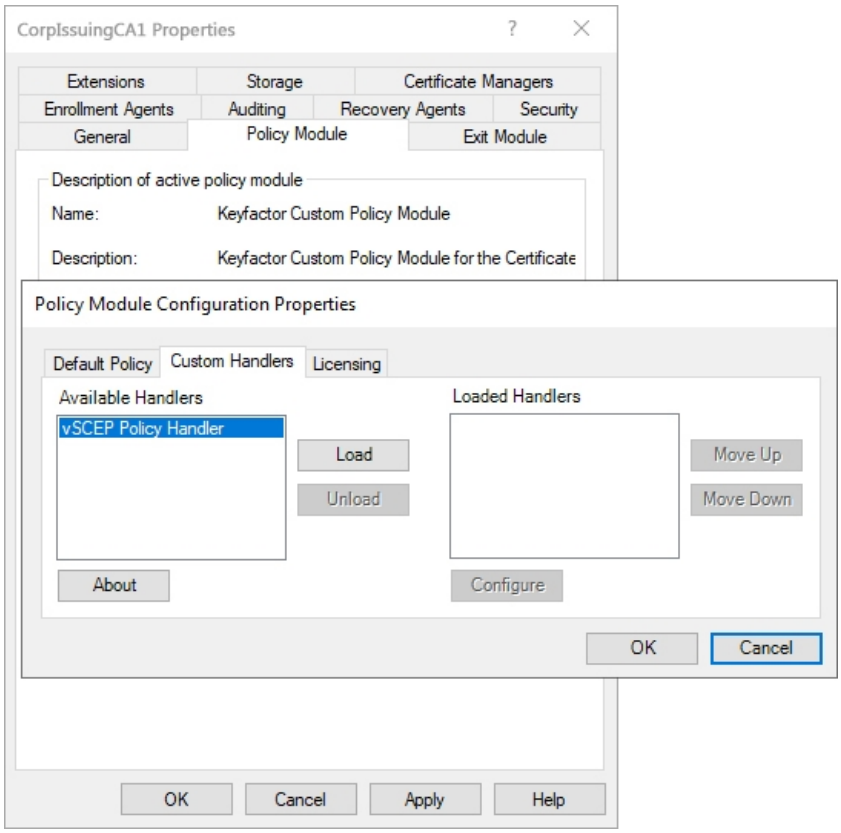

Figure 513: Enable the vSCEP™ Policy Handler

11. On the Custom Handlers tab of the Policy Module Configuration Properties page, highlight the vSCEP™ Policy Handler under Loaded Handlers and click **Configure**.

12. On the vSCEP™ Policy Handler dialog, enter the vSCEP URL at the top of the page. This is the URL for the Keyfactor Command server where the vSCEP service is installed followed by the virtual directory name of the validation service. By default, the virtual directory name is *KeyfactorVSCEP*. Enter the username and password for the Active Directory service account used to authenticate to the vSCEP service on the Keyfactor Command server. Click the Verify button to confirm that the username and password entered are valid. Leave the **Verify Connection on Save** box checked and click **Save**. The URL entered will be tested to confirm that it can be reached and that authentication to it succeeds using the credentials provided.

    Note: The user you enter here needs to be a member of the group you configure for *Allowed Users/Groups* on the vSCEP Service tab in the Keyfactor Command configuration wizard (see vSCEP Services Tab on page 2272).

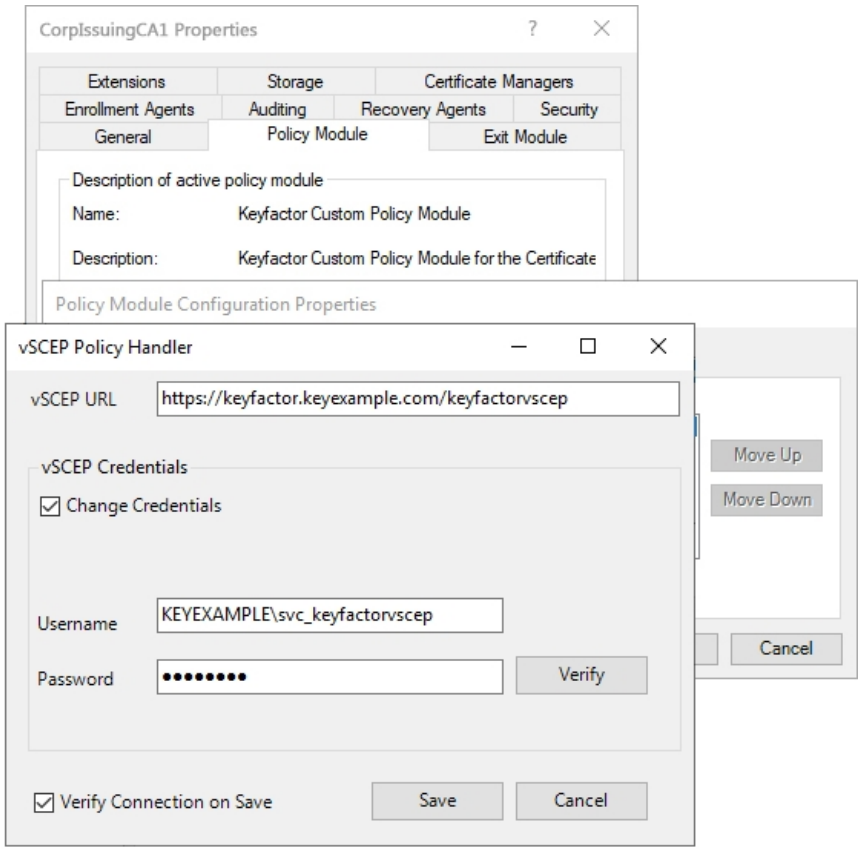

Figure 514: Configure Settings for the vSCEP™ Policy Handler

13. Click **OK** as many times as needed to close the configuration dialogs and save the configuration. You will be prompted to restart the CA services.

4.5.3.4 Install the Keyfactor Whitelist Policy Handler

To begin the Whitelist Policy Handler installation, execute the KeyfactorCAModuleInstaller.msi file from the Keyfactor installation media and install as follows.

Note: The following Windows update affects how certificate requests are built when sent to a Microsoft CA and may cause enrollments done outside Keyfactor Command against a Microsoft CA configured with the Whitelist Policy Handler to fail.
https://support.microsoft.com/en-us/topic/kb5014754-certificate-based-authentication-changes-on-windows-domain-controllers-ad2c23b0-15d8-4340-a468-4d4f3b188f16

1. On the first installation page, click **Next** to begin the setup wizard.

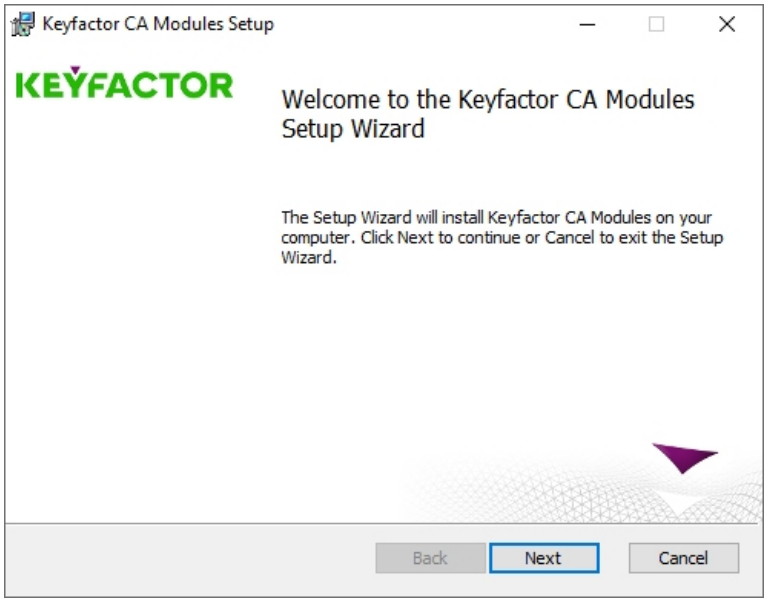

Figure 515: Install Whitelist Policy Handler: Begin Setup Wizard

2. On the next page, read and accept the license agreement and click **Next**.

3. On the next page, select the components to install. For the Whitelist Policy Handler, deselect all the components except the Whitelist Policy Handler component. If desired, you can highlight Keyfactor Custom Policy Module and click **Browse** to select an alternate installation location for the files. The default installation location is:

    C:\Program Files\Keyfactor\Keyfactor CA Modules

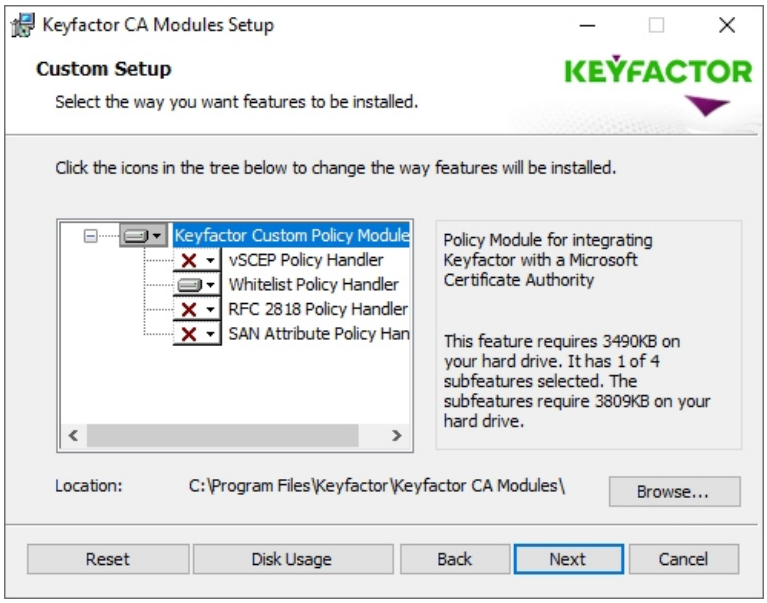

Figure 516: Install Whitelist Policy Handler: Select Components

4. On the next screen, click **Install**.

5. On the final installation wizard page, leave the "Launch the CA MMC snap-in now" box selected and click **Finish**. The Microsoft Certification Authority management tool should start automatically. This can take several seconds.

6. In the Certification Authority management tool, right-click the CA name at the top of the tree and choose **Properties**.

7. In the Properties dialog for the CA on the CA Policy Module tab, click **Select**, highlight the **Keyfactor Custom Policy Module** in the Set Active Policy Module dialog and click **OK**.

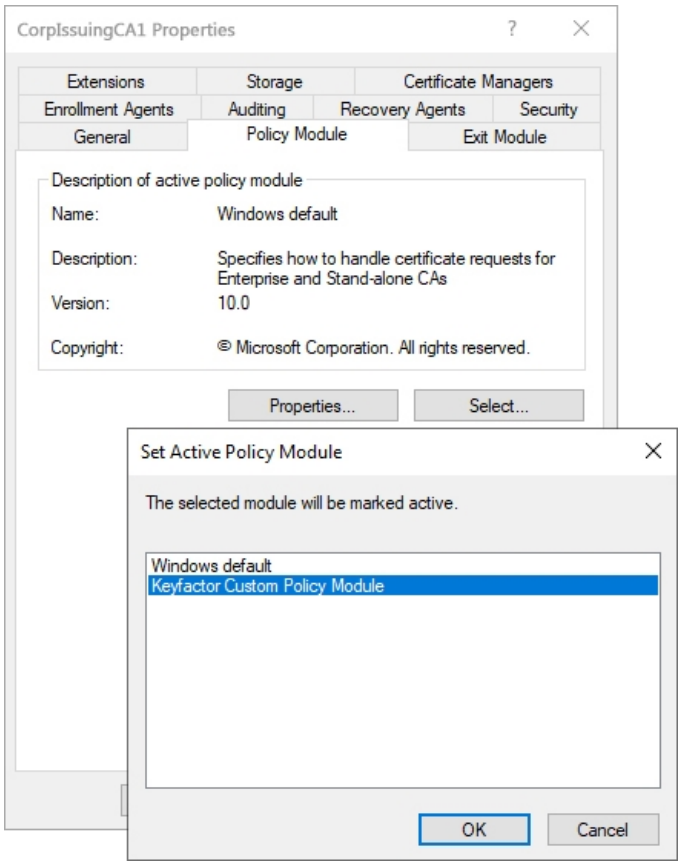

Figure 517: Enable the Keyfactor CA Policy Module

8. In the Properties dialog for the CA on the CA Policy Module tab, click **Properties**.

9. On the Licensing tab of the Policy Module Configuration Properties page, click **Upload License** and browse to locate the license file provided to you by Keyfactor. This file should have the extension CMSLICENSE.

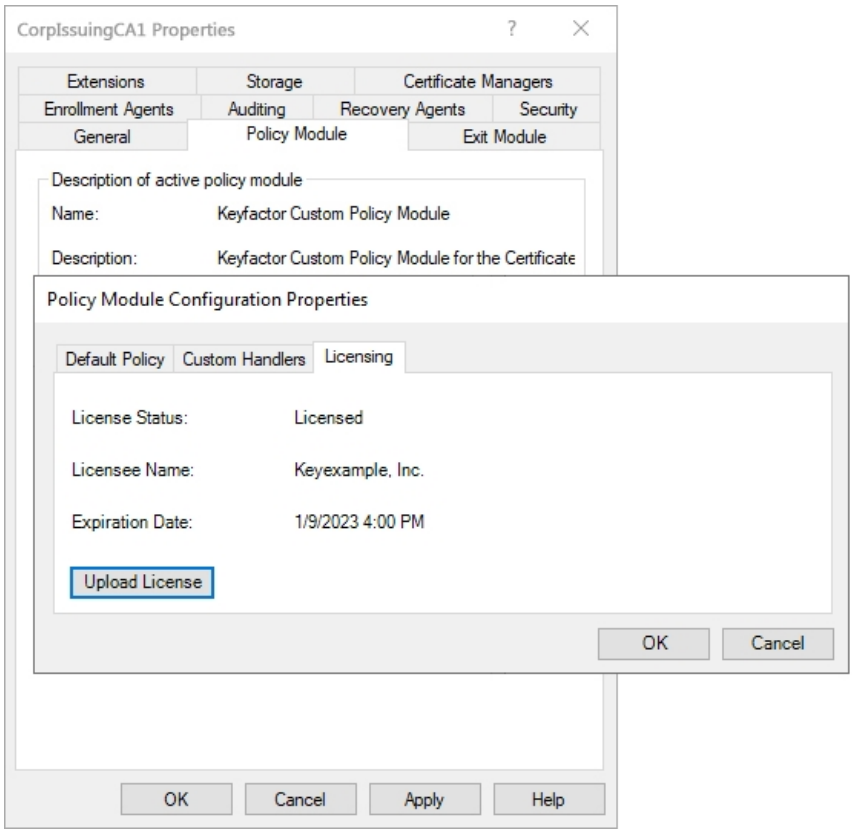

Figure 518: Upload the Keyfactor CA Policy Module License

10. On the Custom Handlers tab of the Policy Module Configuration Properties page, highlight the **CMS Machine Whitelist Policy** on the list of available handlers, click **Load** to move it over to the loaded handlers, and click **OK**.

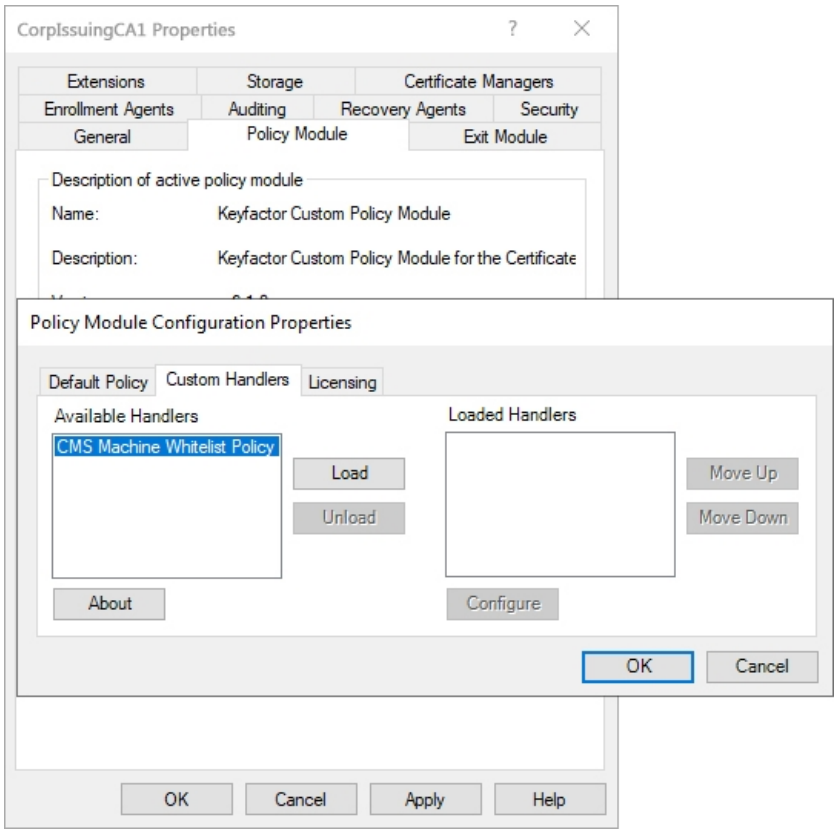

Figure 519: Enable the Whitelist Policy Handler

11. On the Custom Handlers tab of the Policy Module Configuration Properties page, highlight CMS Machine Whitelist Policy under Loaded Handlers and click **Configure**.

12. On the Template tab of the Policy Module Configuration dialog, enter the certificate *template names* (short names), not the template display names, one at a time, of the certificate template(s) you want to manage with the whitelist policy handler and click **Add**. In many cases, the template name is the same as the template display name with the spaces removed. Any templates entered here will be available for enrollment only from machines listed on the Machine Names tab.

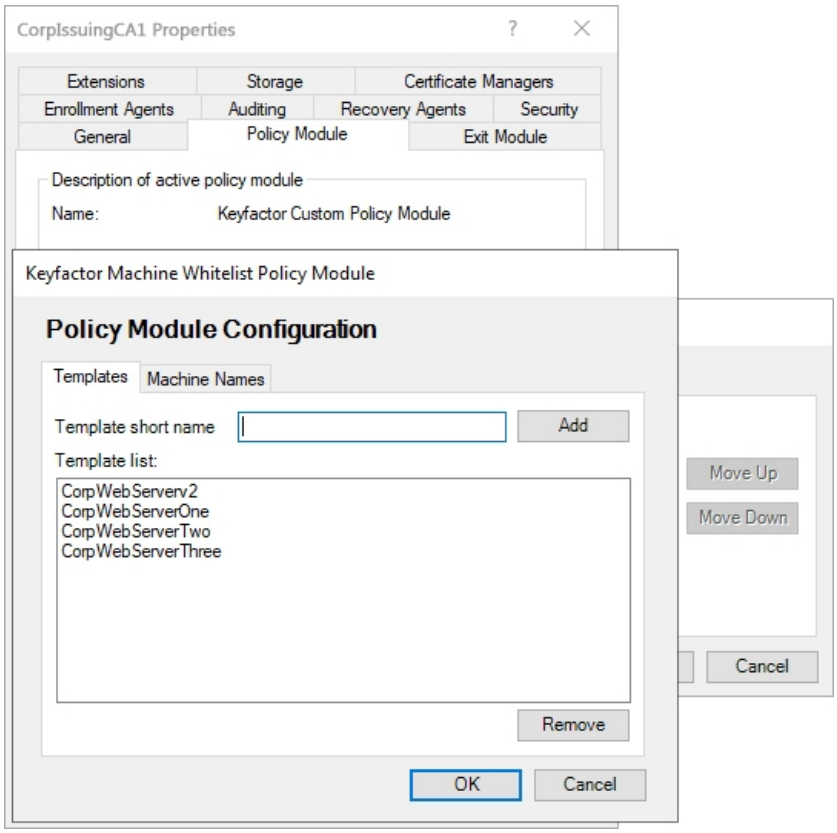

Figure 520: Add Templates for Management with the Whitelist Policy Handler

13. On the Machine Names tab of the Policy Module Configuration dialog, enter the machine names (FQDNs), one at a time, of the machines that you want to manage with the whitelist policy handler and click **Add**. Any machines entered here will be allowed to enroll for the templates listed on the Templates tab.

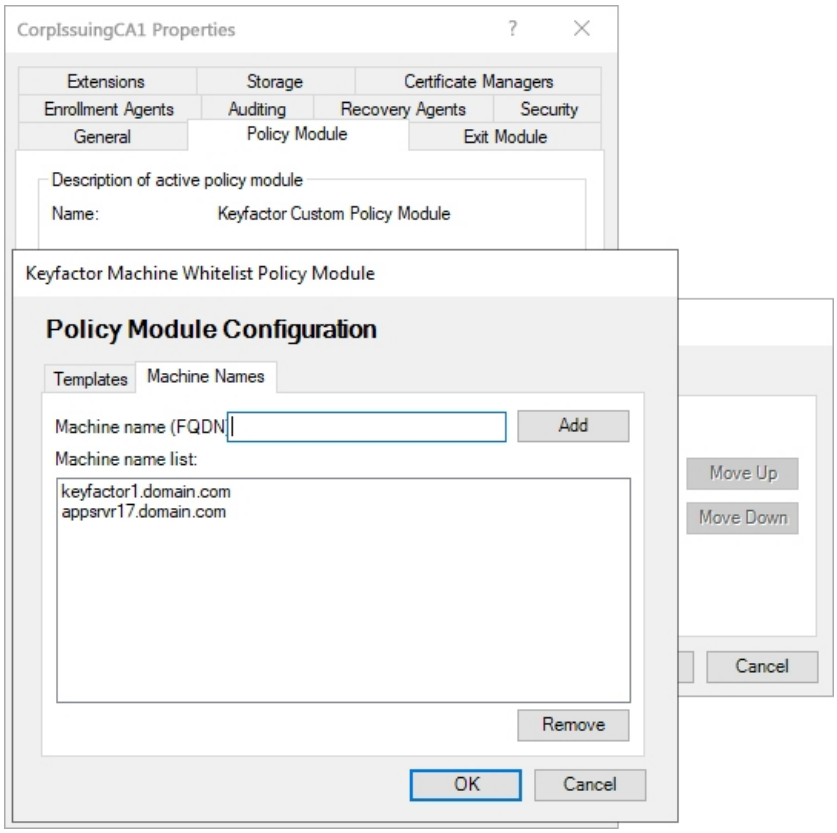

Figure 521: Add Machines for Management with the Whitelist Policy Handler

14. Click **OK** as many times as needed to close the configuration dialogs and save the configuration. You will be prompted to restart the CA services.

4.5.4 Configure Logging for the Keyfactor CA Policy Module

The Keyfactor CA Policy Module provides extensive logging for visibility and troubleshooting. By default, Keyfactor CA Policy Module places its log files in the C:\Keyfactor\logs directory, generates logs at the "Info" logging level and stores the primary logs for two days before deleting them.

To configure logging:

1. On the policy module server where you wish to adjust logging, open a text editor (e.g. Notepad) using the "Run as administrator" option.

2. In the text editor, browse to open the Nlog.config file for the Keyfactor CA Policy Module The file is located in the installation directory for the product, which is the following by default:

   C:\Program Files\Keyfactor\Keyfactor CA Modules\NLog.config

3. Your Nlog.config file may have a slightly different layout than shown here, but it will contain the five fields highlighted in Figure 522: Keyfactor CA Policy Module NLog.config File. The fields you may wish to edit are:

- fileName="C:\Keyfactor\Logs\Keyfactor_CA_Log.txt"

  The path and file name of the active policy module log file, referencing the logDirectory variable.

  > **Important:** If you choose to change the path for storage of the log files, you will need to create the new directory (e.g. D:\KeyfactorLogs) and grant the service account under which the Active Directory Certificate Services service is running full control permissions on this directory.

- archiveFileName="C:\Keyfactor\Logs\Keyfactor_CA_Log_Archive_{#}.txt"

  The path and file name of previous days' orchestrator log files, referencing the logDirectory variable. The orchestrator rotates log files daily and names the previous files using this naming convention.

- maxArchiveFiles="2"

  The number of archive files to retain before deletion.

- name="*" minlevel="Info" writeTo="logfile"

  The level of log detail that should be generated and output to the log file. The default "Info" level logs error and some informational data but at a minimal level to avoid generating large log files. For troubleshooting, it may be desirable to set the logging level to "Debug" or "Trace". Available log levels (in order of increasing verbosity) are:

  - OFF—No logging
  - FATAL—Log severe errors that cause early termination
  - ERROR—Log severe errors and other runtime errors or unexpected conditions that may not cause early termination
  - WARN—Log errors and use of deprecated APIs, poor use of APIs, "almost" errors, and other runtime situations that are undesirable or unexpected but not necessarily "wrong"
  - INFO—Log all of the above plus runtime events (startup/shutdown)
  - DEBUG—Log all of the above plus detailed information on the flow through the system
  - TRACE—Maximum log information—this option can generate VERY large log files

```
<targets>
  <target name="buffered_wrapper" xsi:type="BufferingWrapper" slidingTimeout="true" bufferSize="500" flushTimeout="500">
    <target xsi:type="File" name="logfile" fileName="C:\Keyfactor\logs\Keyfactor_CA_Log.txt" layout="${longdate} ${logger} [${level}] - ${message}"
            archiveFileName="C:\Keyfactor\logs\Keyfactor_CA_Log_Archive_{#}.txt" archiveEvery="Day" archiveNumbering="Rolling" maxArchiveFiles="2" />
  </target>
  <target xsi:type="OutputDebugString" name="String" layout="${longdate} ${logger}::${message}"/>
  <target xsi:type="Debugger" name="debugger" layout="${longdate} ${logger}::${message}"/>
  <target xsi:type="Console" name="console" layout="${logger} ${message}"/>
  <target xsi:type="EventLog" name="eventLog" source="Keyfactor CA Modules"
          eventId="${event-properties:item=eventID}" category="${event-properties:item=categoryID}" layout="${event-properties:item=message}" />
</targets>
<rules>
  <!-- Don't write events to the log file (log file should contain different, more verbose, logging) -->
  <logger name="*-EVENT" minlevel="Info" writeTo="eventLog" final="true" />
  <logger name="*" minlevel="Info"  writeTo="logfile" />
</rules>
```

Figure 522: Keyfactor CA Policy Module NLog.config File

4.5.5 Add Non-Keyfactor SCEP Servers to the Ignore List

This step only needs to be completed if you installed the Keyfactor CA Policy Module with the vSCEP™ Policy Handler.

If your CA for that issues certificates based on SCEP challenges is used by multiple SCEP servers, you will need to add SCEP servers not used for Keyfactor Command vSCEP API requests to the ignore list on the CA running the vSCEP™ Policy Handler. This will allow the vSCEP™ Policy Handler to ignore requests (passing them through to the CA) from the listed SCEP servers. Without this feature, SCEP challenges from non-Keyfactor Command servers would be denied because no data exists against which to verify the certificate details.

The vSCEP™ Policy Handler reads the ignore list in the registry string value **CCMBlacklist**. This field contains a semi-colon-delimited list of SCEP server host names from which all certificate requests should be ignored by the Keyfactor CA Policy Module and passed through to the CA. The **CCMBlacklist** setting can be found in the following registry location:

```
HKEY_LOCAL_MACHINE\SOFTWARE\Certified Security Solutions\vSCEP\Configuration
```

The **CCMBlacklist** registry value does not exist by default. Use the Registry Editor (regedit) to create the **CCMBLacklist** value as a DWORD and populate it with the SCEP server FQDNs for any SCEP servers whose requests should bypass the vSCEP™ Policy Handler.

4.6 Appendices

- Appendix - Troubleshooting Logi Log Files below
- Appendix - Logi Load Balancing: Keyfactor Command Configuration Wizard Setup on the next page
- Appendix - Configuration Wizard Errors in the Logs on page 2354

4.6.1 Appendix - Troubleshooting Logi Log Files

When troubleshooting Logi, the first thing to try is setting the *Debug Embedded Reports* application setting to **True** (see Application Settings: Console Tab on page 554 in the *Keyfactor Command Reference Guide*). This allows the reports to output errors with debug level information if they generate errors. If this does not generate the information necessary to resolve the problem, it can sometimes be helpful to modify the Keyfactor Analysis web.config file to allow IIS to show the actual error the application is experiencing at a lower level. To configure this:

1. Browse to the *Logi* directory under the installed directory for your Keyfactor Command implementation. By default, this is:
   C:\Program Files\Keyfactor\Keyfactor Platform\Logi
2. Using a text editor opened with the "Run as administrator option, open the web.config file for editing.
3. Find the <customErrors mode="RemoteOnly"/> section and change this to <customErrors mode="On"/>.
4. Look for the debug output in the *Logi\rdDownload* directory under the installed directory for your Keyfactor Command implementation. By default, this is:
   C:\Program Files\Keyfactor\Keyfactor Platform\Logi\rdDownload

Tip: If you do not find debug output when running a report manually in the Management Portal, try scheduling a report for delivery via email or saving to disk using the Report Manager. Debugging operates differently for these two modes of running a report.

Note: When the portal experiences a 500 error, Logi logs will not be written to the usual output directory.

```
<system.web>
  <!--  DYNAMIC DEBUG COMPILATION
        Set compilation debug="true" to insert debugging symbols (.pdb information)
        into the compiled page. Because this creates a larger file that executes
        more slowly, you should set this value to true only when debugging and to
        false at all other times. For more information, refer to the documentation about
        debugging ASP.NET files.
  -->
  <compilation defaultLanguage="vb" debug="true" />

  <!--  CUSTOM ERROR MESSAGES
        Set customErrors mode="On" or "RemoteOnly" to enable custom error messages, "Off" to disable.
        Add <error> tags for each of the errors you want to handle.
  -->
  <customErrors mode="RemoteOnly" />
  <!--  AUTHENTICATION
        This section sets the authentication policies of the application. Possible modes are "Windows",
        "Forms", "Passport" and "None"
  -->

  <authentication mode="Windows" />
```

Figure 523: Logi web.config

4.6.2 Appendix - Logi Load Balancing: Keyfactor Command Configuration Wizard Setup

In order for the Keyfactor Command Management Portal Dashboard and Reports to load when using a load balancer, the Keyfactor Command Configuration Wizard should have the following configuration on each of the application servers:

- On the Keyfactor Command Portal Tab, the Host Name must be the Load Balanced URL.

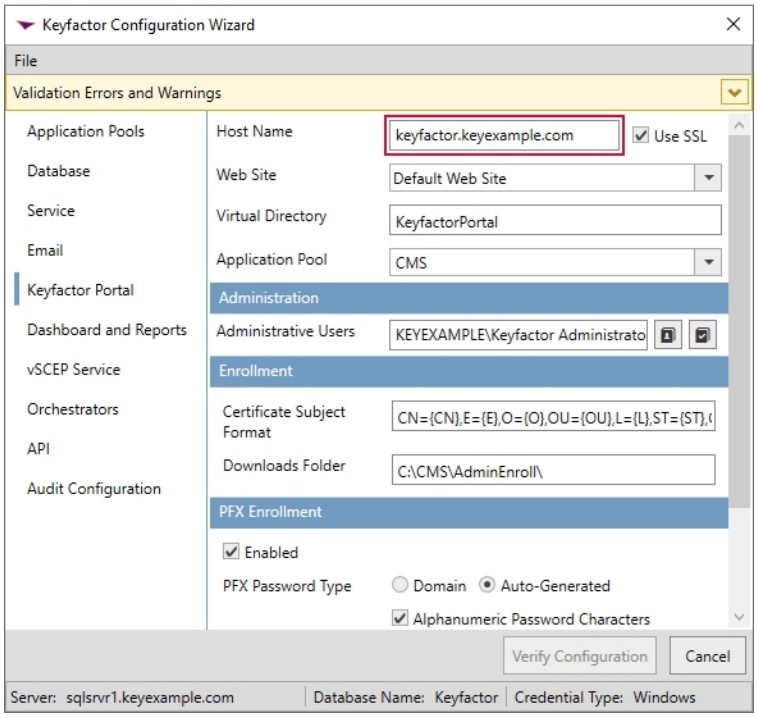

Figure 524: Logi Configuration Settings—Keyfactor Command Portal Tab

- Dashboard and Reports Tab:
  - The Host Name must be the Load Balanced URL. This is the host name that the Management Portal server uses to connect to the Logi Analytics Platform, and it therefore needs to be the name used on the internal side of the network.
  - The Keyfactor Command Site IP Address(es) must contain:
    - The application machine IPv4 addresses for all of the servers that will be load balanced.
    - The application machine IPv6 addresses for all of the servers that will be load balanced if IPv6 is enabled.
    - The internal IPv4 addresses of the load balancer that the load balancer will use to connect to the application servers.

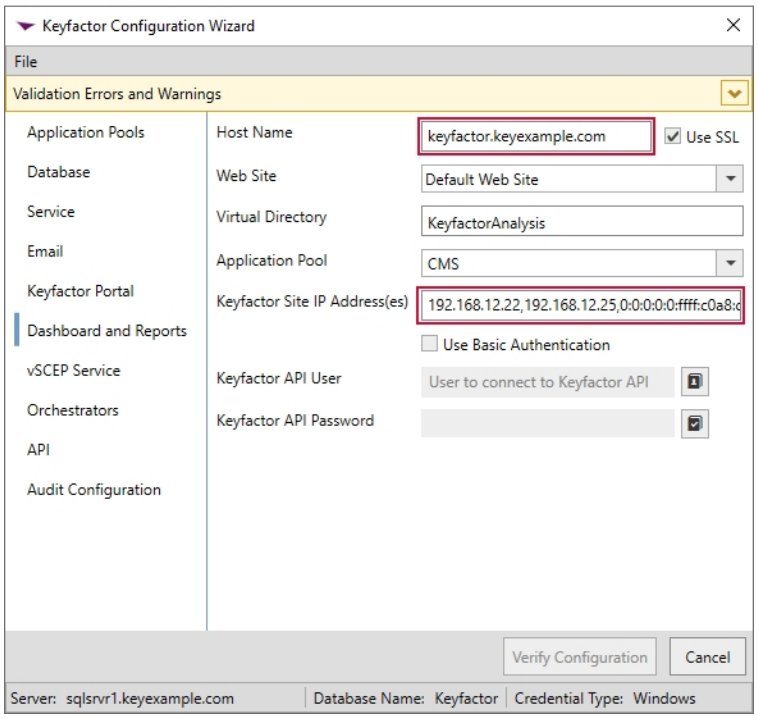

Figure 525: Logi Configuration Settings—Keyfactor Command Dashboards and Reports Tab

Tip: All IP Addresses that could be used internally to connect to the Logi application must be in the Dashboard and Reports configuration section in the configuration wizard. This includes the application host IPs and the load balancer IPs. It is also recommended that the host file is modified to map the load balancer URL to the local IP address.

- Load Balancer

  On the load balancer, a new rewrite rule needs to be made that changes the outbound URL from the application servers. Logi sends the HostName.domain.com/KeyfactorAnalysis URL back to the browser instead of the LoadBalancer.URL.com/KeyfactorAnalysis URL that the browser needs to complete the Logi authorization. In short, an Outbound rewrite rule needs to be created on the Load Balancer that does the following: HostName_URL/KeyfactorAnalysis needs to be converted to LoadBalancer_URL/keyfactorAnalysis

- Load Balancer - Session Affinity

  There are two load balancing scenarios based on user session management: Sticky session (recommended) and Non-Sticky session. In the Sticky session scenario, each user is assigned to a server by the load balancer and all the requests sent by this user are answered by the same server, for as long as the user's session persist. This is the recommended approach and does not require you to centralize the rdDataCache folder of the application. We strongly recommend using Sticky session instead. You can learn more about Load Balancing with Info applications on DevNet.

4.6.3 Appendix - Configuration Wizard Errors in the Logs

If incoming web request runs before the configuration is fully completed, you may encounter the following errors in the portal log file after upgrading. These errors are not something to be worried about. They just indicate that the web request was still looking at an old version of the database prior to it being completely upgraded.

```
2021-11-15 12:41:36.5155 Keyfactor.EF.KeyfactorExecutionStrategy [Error] - SqlException
with number 207 occurred, not attempting to retry the connection.
2021-11-15 12:41:36.5780 Keyfactor.EF.KeyfactorExecutionStrategy [Error] - Invalid column
name 'Immutable'.

Invalid column name 'SubscriberTerms'.

2021-11-15 12:41:36.6249 ASP.global_asax [Error] - An uncaught application error occurred:
An error occurred while executing the command definition. See the inner exception for
details.

2021-11-15 12:41:37.3281 ASP.global_asax [Error] - An uncaught application error occurred:
An item with the same key has already been added.

at System.ThrowHelper.ThrowArgumentException(ExceptionResource resource)
```

5.0 Installing Orchestrators

Keyfactor offers several orchestrators (a.k.a. agents) that may be used to interact with and enhance the functionality of the Keyfactor Command Server.

Tip: Keyfactor recommends that you check the Keyfactor GitHub Site (https://keyfactor.github.io/integrations-catalog/) with each release that you install to check if you will need to download the updated orchestrators to work with that version of Keyfactor Command.

This guide covers installation of the following orchestrators:

- Keyfactor Universal Orchestrator
  The Keyfactor Universal Orchestrator replaces the Keyfactor Windows Orchestrator and runs on both Windows or Linux servers. It can be used to:
  - Interact with Windows servers (a.k.a. IIS certificate stores) to provide certificate management (installations on Windows only).
  - Interact with FTP capable devices to provide certificate management.
  - Run SSL discovery and monitoring tasks.
  - Manage synchronization of certificate authorities in remote forests (installations on Windows only).
  - Collect logs from the orchestrator for central review.
  - Run custom jobs to provide certificate management capabilities on a variety of platforms and devices.
  - Run custom jobs to execute tasks outside the standard list of certificate management functions. This powerful feature can execute just about any job that requires processing on the orchestrator and submitting data back to Keyfactor Command.

  As of this release, the following functions, some of which were part of the Keyfactor Windows Orchestrator, are now included among the custom extensions supported for the Keyfactor Universal Orchestrator:
  - Remote Java keystore certificate management.
  - Remote PEM store certificate management.
  - Interact with F5 devices for certificate management.
  - Create new bindings for IIS web sites (the built-in IIS management tool will replace the certificate bound to a web site but not create new bindings) and manage certificates in both the Web Hosting certificate store and the Personal certificate store.
  - Interact with NetScaler devices for certificate management.

  These custom extensions are publicly available at:

  https://keyfactor.github.io/integrations-catalog/content/orchestrator

  The final release of the Keyfactor Windows Orchestrator was version 8.7. This version of the Keyfactor Windows Orchestrator is fully compatible with Keyfactor Command version 10.3. Keyfactor will continue to support the Keyfactor Windows Orchestrator. However, all new integrations and extensions will be delivered via the new Keyfactor Universal Orchestrator. Keyfactor recommends that customers use the Keyfactor

Universal Orchestrator moving forward as new integrations become available. Customers with one or more of these types of certificate stores may wish to retain one or more legacy Keyfactor Windows Orchestrators to manage these types of stores until such time as new integrations become available for the Keyfactor Universal Orchestrator.

- Keyfactor Java Agent
  The Keyfactor Java Agent runs on Windows or Linux servers and is used to perform discovery of Java keystores and PEM certificate stores, to inventory discovered stores, and to push certificates out to stores as needed. In addition, the Keyfactor Java Agent can be extended to create custom certificate store jobs.
- Keyfactor Bash Orchestrator
  The Keyfactor Bash Orchestrator runs on Linux servers and is used to perform discovery and management of SSH public keys, including installation of new keys and automated removal of unauthorized keys.

Keyfactor also offers a variety of tools to allow users to develop custom orchestrators and extensions, including:

- Keyfactor AnyAgent Framework

  The AnyAgent capability of the Keyfactor Universal Orchestrator, Keyfactor Windows Orchestrator, and Java Agent allows management of certificates regardless of source or location by allowing customers to implement custom agent functionality.
- Keyfactor Integration SDK

  The Keyfactor Integration SDK (software development kit) includes a variety of tools for building a custom orchestrator, including the Keyfactor Native Agent, which is a reference implementation intended for customers wanting to include Keyfactor Command certificate store management functionality in embedded or other platforms.
- Keyfactor Orchestrator NuGet Package

  The Keyfactor Orchestrator NuGet package is designed to allow customers to build custom extensions for the Keyfactor Universal Orchestrator.
- Keyfactor GitHub Site

  Keyfactor offers several publicly available integrations and plugins for the Keyfactor platform in the Keyfactor GitHub. Find all the latest developer tools and resources to integrate the Keyfactor platform with your PKI, Cloud, and DevOps infrastructure.

  https://keyfactor.github.io/

These tools for developing custom orchestrators and extensions are not documented in this guide. For more information about these and other custom orchestrator solutions, contact your Keyfactor representative.

5.1 Orchestrator Job Overview

Keyfactor orchestrators can be used to perform a wide variety of jobs. Out of the box, orchestrators can manage certificate stores, manage SSH keys, perform SSL scanning, fetch system logs, and synchronize certificates from CAs in remote forests. Orchestrator jobs fall into these broad types:

- Certificate Store Jobs

  This type of job includes the built-in jobs for managing certificate stores, based on the type(s) of certificate stores supported by the orchestrator, and custom-built certificate store jobs that can be added with an

extension (see Installing Custom-Built Extensions on page 2392) or script (see Configuring Script-Based Certificate Store Jobs on page 2395).

Certificate store jobs (built-in or custom-built), are managed in Keyfactor Command with certificate store types. If you're adding a custom-built certificate store job, you'll need to add a user-defined certificate store type to go with it (see Certificate Store Types on page 602 in the *Keyfactor Command Reference Guide* and Certificate Store Types on page 1229 in the *Keyfactor Web APIs Reference Guide*).

- Custom Jobs

  This type of job is intended to implement just about anything else you need an orchestrator to do other than manage certificate stores. The built-in fetch logs job is an example of a custom job.

  Custom jobs are managed in Keyfactor Command with custom job types. If you're adding a custom job, you'll need to add a custom job type to go with it (see Custom Job Types on page 1279 in the *Keyfactor Web APIs Reference Guide*).

  Custom jobs are supported only by the Keyfactor Universal Orchestrator.

- Other Jobs

  This type of job includes the built-in jobs for SSL scanning and certificate synchronization from remote CAs.

Prescripts and Postscripts

All of the job types supported by the Keyfactor Universal Orchestrator—including the built-in jobs—support executing a prescript and/or postscript as part of the job. A prescript might be used to fetch credentials from a privilege access management (PAM) solution to pass in to the username and password parameters for a certificate store. A postscript might be used to restart the web service (e.g. Apache) after performing a management job to replace the certificate in the certificate store for the web server. Prescripts and postscripts for all types of jobs are configured similarly to the description provided for installing custom-built extensions (see Installing Custom-Built Extensions on page 2392).

Orchestrator Job Flow

An orchestrator job begins when an orchestrator queries Keyfactor Command to ask for jobs and the Keyfactor Command orchestrator API returns a list of the jobs the orchestrator needs to run. The flow continues as shown in the following chart.

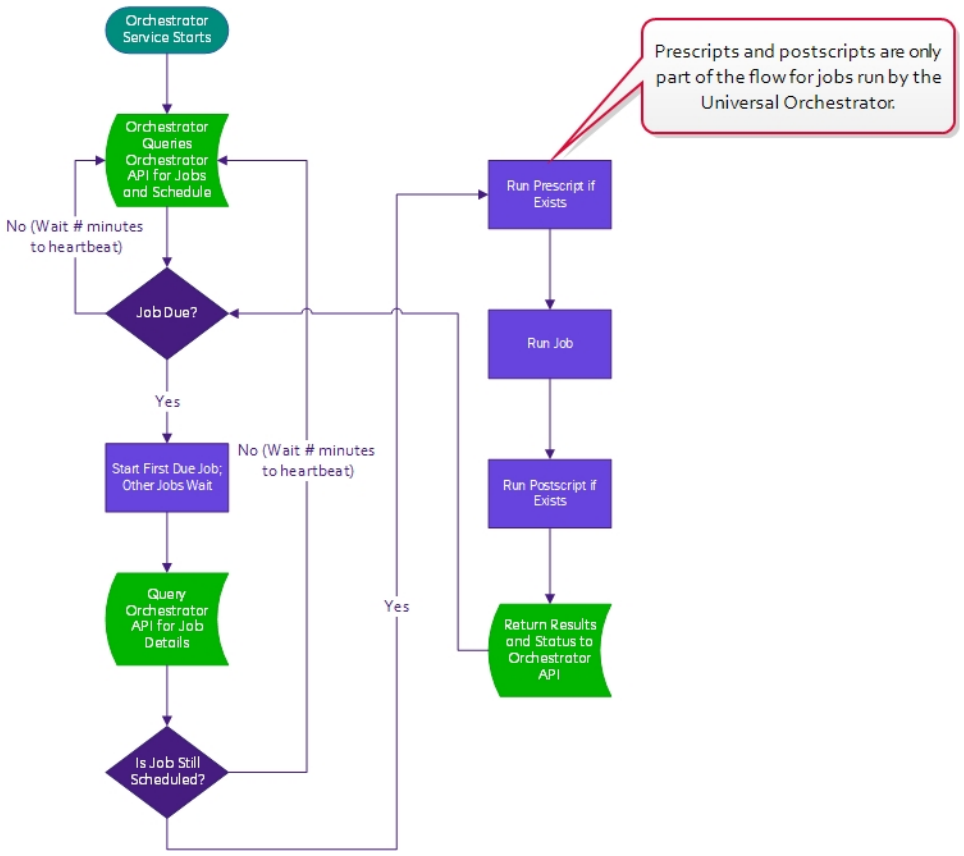

Figure 526: Orchestrator Job Flow

5.2 Universal Orchestrator

The Keyfactor Universal Orchestrator is designed to run jobs at the request of the Keyfactor Command server. Jobs primarily perform certificate management tasks, but other types of operations are also supported. The orchestrator operates as a .NET Core based service on either a Windows or Linux server and communicates with a Keyfactor Command server to receive job tasks and report job results. Along with the job results, data can be returned to the Keyfactor Command server and stored in the Keyfactor Command SQL database. Extensions are hosted by the orchestrator and implement the jobs to be executed.

The orchestrator includes these built-in extensions:

- Discover and monitor certificates at TLS 1.3 endpoints either within the local network or across the internet using any of the 5 ciphersuites mentioned in appendix B.4 of RFC 8446. Certificates from the results of SSL discovery and monitoring are imported into Keyfactor Command for viewing, reporting and alerting purposes. Scanning using server name indication (SNI) is supported.
- Manage and deliver certificates in the machine certificate store on Windows servers using the Management Portal, and (optionally) bind the certificates to Internet Information Services (IIS) web sites. This feature is supported only on Windows installations.

- Manage and deliver certificates in PEM stores on FTP capable devices using the Management Portal, and associate them with PEM stores on FTP capable devices. Certificates from PEM stores on FTP capable devices can be imported into Keyfactor Command for viewing, reporting and alerting purposes.
- Retrieve logs generated on the orchestrator via the Keyfactor Command Management Portal. This task returns up to 2 MB of log data from the end of the orchestrator log file to be viewed in the Management Portal.
- Manage certificates from remote Microsoft Certificate Authorities (CAs) using the Management Portal. Certificates from remote CAs can be imported into Keyfactor Command for viewing, reporting and alerting purposes. This feature is supported only on Windows installations.

  If the remote CA is domain-joined to a domain in the remote forest, the Universal Orchestrator may be installed on the CA itself or on a separate server joined to a domain in the same forest (generally a server in the same domain as the CA). Multiple CAs in the same remote forest can be managed with a single Universal Orchestrator server. However, if the remote CA is not domain-joined, the Universal Orchestrator must be installed on the remote CA server.

  Note: The Universal Orchestrator does not support certificate enrollment for remote CAs. If you need this capability, you will need to use the *Explicit Credentials* option in the Management Portal CA configuration (see the Adding or Modifying a CA Record on page 311 in the *Keyfactor Command Reference Guide*) or the Keyfactor Cross-Forest Gateway.

In addition, two types of custom extensions are supported:

- Manage and deliver certificates to certificate stores on various platforms and devices using custom certificate store types and orchestrator jobs in the Keyfactor Command Management Portal. With custom extensions, you can manage F5 devices, NetScaler devices, AWS resources and more.
- Run custom jobs on the orchestrator that fall outside the standard certificate management tasks. With custom jobs, you can perform operations locally on the orchestrator—or initiate them remotely across the network—and then report results back to Keyfactor Command along with data collected from the jobs, if any.

Custom extensions may be developed by Keyfactor or end users. For more information about custom extensions, contact your Keyfactor representative.

Tip: Installation of instances of both the Keyfactor Universal Orchestrator and Keyfactor Command Windows Orchestrator together on the same machine is supported. Note that the two orchestrators cannot share the same orchestrator name (used to identify the orchestrator in Keyfactor Command), so at least one of them needs to be installed using a name other than the default of the value of the COMPUTERNAME environment variable. For the Keyfactor Universal Orchestrator, this is the -OrchestratorName parameter (see Install the Universal Orchestrator on Windows on page 2372).

5.2.1 Preparing for the Universal Orchestrator

This section describes the steps that need to be taken prior to a Keyfactor Universal Orchestrator installation to install the prerequisites, create the required supporting components, and gather the necessary information to complete the Universal Orchestrator installation and configuration process.

5.2.1.1 System Requirements

The Keyfactor Universal Orchestrator is supported on the following operating systems:

- Windows Server 2019
- Oracle Linux 7 or higher
- Red Hat Enterprise 7 or higher
- Ubuntu 16 or higher

Note: Older versions of the Universal Orchestrator will work with newer versions of Keyfactor Command, but not the other way around (see the Compatibility Matrix in the *Keyfactor Command Documentation Suite*). The current version of the Universal Orchestrator requires Keyfactor Command version 10.0 or greater.

Important: Microsoft support for .NET Runtime version 3.1 was deprecated at the end of 2022. Instructions for upgrading to version 6.0 are included in the *Tip*, below.

Windows Application Requirements

The Universal Orchestrator has the following requirements on Windows.

- The orchestrator requires the Microsoft .NET Runtime version 6.0 (x64). Version 6.0 is available for download from Microsoft:

  https://dotnet.microsoft.com/download/dotnet/6.0/runtime

  You need only the .NET Runtime (x64), not the ASP.NET Core Runtime or ASP.NET Core Hosting Bundle. At the above link, this would be the **Download x64** option under the "Run console apps" heading.

  You can use the following PowerShell command to check the .NET core version(s) installed on a server (if any):

  ```
  dotnet --list-runtimes
  ```

  Output from this command will look something like this if you have the correct 6.0 x64 version of the .NET Runtime installed (notice the path is in C:\Program Files, not C:\Program Files (x86), indicating this is the x64 version):

  ```
  Microsoft.NETCore.App 6.0.11 [C:\Program Files\dotnet\shared\Microsoft.NETCore.App]
  ```

- If you intend to use the orchestrator to manage certificates on remote Windows machine store certificates (servers other than the server on which the orchestrator is installed) using the IIS Personal, IIS Trusted Roots, or IIS Revoked store types, make sure that TCP port 445 is open between the orchestrator and the remote servers.
- If you intend to use the orchestrator to manage certificates from remote Microsoft CAs (CAs outside the forest in which Keyfactor Command is installed or forests in a two-way trust with this forest), the orchestrator requires the Microsoft Visual C++ 2019 (or later) redistributable for x64. This is available for download from Microsoft:

  https://aka.ms/vs/16/release/vc_redist.x64.exe

  The Microsoft Visual C++ Redistributable appears as an application in the Windows Apps & features.

Linux Application Requirements

The following applications are required in order to install the Universal Orchestrator on Linux servers.

Microsoft .NET 6.0 Runtime

The orchestrator requires the Microsoft .NET Runtime version 6.0 (x64). Information about this is available from Microsoft:

https://docs.microsoft.com/en-us/dotnet/core/install/linux

You need only the .NET Runtime (x64), not the ASP.NET Core Runtime, but it won't hurt anything to install both the .NET and ASP.NET Core runtimes as suggested in the Microsoft documentation for installing .NET on Linux.

For the most part, it can be installed via the OS package manager. The method to complete this varies depending on the Linux operating system. For example, for Ubuntu 20.04, the following commands will install the correct version of .NET:

```
wget https://packages.microsoft.com/config/ubuntu/20.04/packages-microsoft-prod.deb
 sudo dpkg -i packages-microsoft-prod.deb
 sudo apt-get update
 sudo apt-get install apt-transport-https
 sudo apt-get install dotnet-runtime-6.0
```

You can use the following command to check the .NET version installed on a server (if any):

```
dotnet --list-runtimes
```

Output from this command will look something like this if you have the correct 6.0 version of the .NET Runtime installed:

```
Microsoft.NETCore.App 6.0.6 [/usr/share/dotnet/shared/Microsoft.NETCore.App]
```

jq

The orchestrator can only be installed on a Linux server that has jq installed. You can use the following command to check the jq version of a server:

```
jq --version
```

systemd

The orchestrator requires a Linux server that uses the systemd service manager. You can use the following command to test whether a system is running systemd:

```
ps -p 1
```

bash

The orchestrator can only be installed on a Linux server that is running bash version 4.3 or higher. You can use the following command to check the bash version of a server:

```
bash --version
```

curl

The orchestrator can only be installed on a Linux server that has curl installed. You can use the following command to check the curl version of a server:

```
curl --version
```

Tip: If you have an existing installation of the Universal Orchestrator using the older Microsoft .NET Runtime version 3.1, you do not need to reinstall the orchestrator to upgrade the .NET version. To update your existing Universal Orchestrator to the latest .NET version:

1. On the Universal Orchestrator machine, browse to locate the Orchestrator.runtimeconfig.json file in your installation directory. By default, this is:

   ```
   Windows: C:\Program Files\Keyfactor\Keyfactor
   Orchestrator\Orchestrator.runtimeconfig.json
   Linux: /opt/keyfactor/orchestrator/Orchestrator.runtimeconfig.json
   ```

2. Using a text editor, open the Orchestrator.runtimeconfig.json file for editing and add the following property to the runtimeOptions section:

   ```
   "rollForward": "LatestMajor"
   ```

   Being sure to add a comma at the end of the previous row, resulting in a final file that looks something like:

   ```
   {
      "runtimeOptions": {
         "tfm": "netcoreapp3.1",
         "framework": {
            "name": "Microsoft.NETCore.App",
            "version": "3.1.0"
         },
         "rollForward": "LatestMajor"
      }
   }
   ```

3. Save the Orchestrator.runtimeconfig.json file.
4. Uninstall the Microsoft .NET Runtime version 3.1 (x64) and install the 6.0 version.
5. Restart the Universal Orchestrator service (see Start the Universal Orchestrator Service on page 2401).

5.2.1.2 Create Service Accounts for the Universal Orchestrator

The Keyfactor Universal Orchestrator makes use of up to two service accounts to allow it to communicate with the Keyfactor Command server. These two service accounts work together to transfer information from the Universal Orchestrator to the Keyfactor Command server. The two service accounts can be thought of as players on two sides of a fence, with the service account that the Universal Orchestrator runs as lobbing information over the

fence to the service account that communicates with the Keyfactor Command server side to catch and hand to the Keyfactor Command server. Below these are referred to as the Universal Orchestrator service account and the Keyfactor Command connect service account.

The service accounts need to be created prior to installation of the Universal Orchestrator software (except as noted below for installations on Linux), and the person installing the Universal Orchestrator software needs to know the domain (if applicable), username and password of each service account.

Universal Orchestrator Service Account

Your choice of service account may vary depending on the operating system on which you are installing the orchestrator:

- **Universal Orchestrator on Windows**

  When the Universal Orchestrator is installed on Windows, you may use either the built-in Network Service account or a custom service account as the Universal Orchestrator service account. Keyfactor recommends using the default of Network Service unless you have a need to use a custom service account. If you choose to use a custom service account, it may be a standard Active Directory service account, an Active Directory group managed service account (gMSA), or a local machine account. Of the custom service account choices, an Active Directory account is more typically used unless the machine is not domain-joined. If you use an Active Directory service account, it needs to be a service account in the forest in which the Universal Orchestrator is installed. This is not necessarily the same forest as the forest in which the Keyfactor Command server is installed. The Universal Orchestrator on Windows has several possible roles, and the choice of service account may vary depending on these roles:

Certificate Store Management

If your Universal Orchestrator will be managing certificate stores, you may choose to run the orchestrator as the built-in Network Service account or as an Active Directory service account. However, if you plan to use the Universal Orchestrator to manage IIS certificate stores, you *must* use an Active Directory service account because of the permissions that must be granted on each server where you will be managing IIS certificate stores (see Configure the Targets for IIS Management on page 2389). A local account is generally not used in this role.

SSL Management

If your Universal Orchestrator SSL discovery and monitoring, you may choose to run the orchestrator as the built-in Network Service account or as a custom service account.

CA Management

If your Universal Orchestrator will be providing certificate synchronization from a remote CA, the Universal Orchestrator service account needs to be able to read the CA(s) in the forest in which the Universal Orchestrator is installed to retrieve certificates and templates from them. When the Universal Orchestrator is used in this configuration, this is typically a forest other than the forest in which the Keyfactor Command server is installed. For domain-joined CAs, you would typically use an Active Directory service account in the remote forest (the forest where the Universal Orchestrator is installed). For a non-domain-joined CA, you may use a

local account created on the CA as the Universal Orchestrator service account instead of a domain account.

Custom Extensions

Keyfactor offers several publicly available custom extensions for the Universal Orchestrator in the Keyfactor GitHub. Many of these will operate correctly with a Universal Orchestrator service account of Network Service, but some may require a custom account. Check the specific documentation for each custom extension for more information:

`https://keyfactor.github.io/integrations-catalog/content/orchestrator`

The Keyfactor Orchestrator Service on the server on which the Universal Orchestrator is installed runs as the Universal Orchestrator service account. This service account requires local "Log on as a service" permissions; this permission is granted automatically during installation.

- **Universal Orchestrator on Linux**

  For the purposes of this documentation, it is assumed that Linux machines will be non-domain joined and will use a local account to run the Universal Orchestrator.

  For Linux systems, Keyfactor recommends running the service as an account other than root. The default Universal Orchestrator service account of *keyfactor-orchestrator* will be created automatically during the install if the *force* option is used. If you prefer not to use the *force* option, you may create a local service account before running the installation script.

Keyfactor Command Connect Service Account

For the Keyfactor Command connect service account, a standard Active Directory service account in the primary Keyfactor Command server forest is used. Group managed service accounts are not supported in this role. This service account appears in the Management Portal Orchestrator Management grid as the Identity for the Universal Orchestrator.

Tip: If the Universal Orchestrator is installed on Windows in the same forest as the Keyfactor Command server, the same Active Directory service account may be used as both the Universal Orchestrator service account and the Keyfactor Command connect service account, if desired.

Permissions

The user installing the orchestrator must have the SeBackupPrivilege and SeRestorePrivilege rights on the Keyfactor Command server. Normally, administrators are granted these permissions by default, but you should confirm the permissions prior to starting the install. These permissions can be set through Group Policy or Local Security Policy, and can be found under "Local Policies\User Rights Assignment" as "Back up files and directories" and "Restore files and directories".

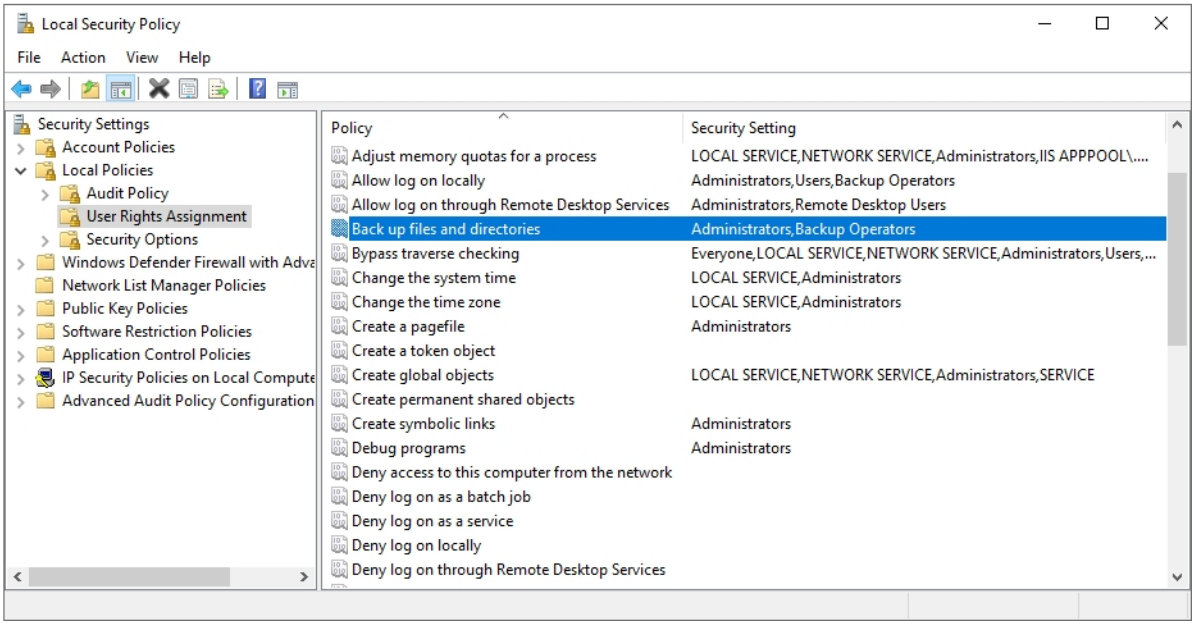

Figure 527: Local Security Policy

For more information on this from Microsoft, see:

https://docs.microsoft.com/en-us/windows/win32/api/userenv/nf-userenv-loaduserprofilea#remarks

5.2.1.3 Configure Certificate Root Trust for the Universal Orchestrator

Keyfactor recommends using HTTPS to secure the channel between each Keyfactor Universal Orchestrator and the Keyfactor Command server(s). This requires an SSL certificate configured in IIS on the Keyfactor Command server (s). This certificate can either be a publicly-rooted certificate (e.g. from DigiCert, Entrust, etc.), or one issued from a private certificate authority (CA). If your Keyfactor Command server is using a publicly rooted certificate, the orchestrator server may already trust the certificate root for this certificate. However, if you have opted to use an internally-generated certificate, your orchestrator server may not trust this certificate. In order to use HTTPS for communications between the orchestrator and the Keyfactor Command server with a certificate generated from a private CA, you may need to import the certificate chain for the certificate into either the local machine certificate store on the orchestrator server on Windows or the root certificate store on Linux.

Note: The CRL(s) for the Keyfactor Command certificate need to be available to the orchestrator (see Troubleshooting on page 2444).

Installations on Windows

If the public key infrastructure (PKI) that issued the certificate has only a root CA, the root certificate from this CA must be installed in the Trusted Root Certification Authorities store under Local Computer on the orchestrator server. If the PKI that issued the certificate has both a root and issuing CA, the root certificate must be installed in the Trusted Root Certification Authorities store under Local Computer on the orchestrator server and the issuing

CA certificate must be installed in the Intermediate Certification Authorities store under Local Computer on the orchestrator server.

Installations on Linux

The location of the OpenSSL trusted root store varies depending on your Linux implementation. The root certificate must be installed in the appropriate location for the operating system before beginning the installation.

5.2.1.4 Grant the Orchestrator Service Account Permissions on the CAs

This step only needs to be completed if you plan to use the Keyfactor Universal Orchestrator for remote CA synchronization.

In order for the Universal Orchestrator to be able to synchronize certificates from the remote CA(s) to the Keyfactor Command database, the Universal Orchestrator service account—the identity under which the orchestrator in the remote forest runs—must have permissions to read the CA database(s) in the remote forest.

In the management console for each CA that the orchestrator will interact with, open the properties for the CA and grant the service account that the orchestrator runs as (see Create Service Accounts for the Universal Orchestrator on page 2362) read permissions before continuing.

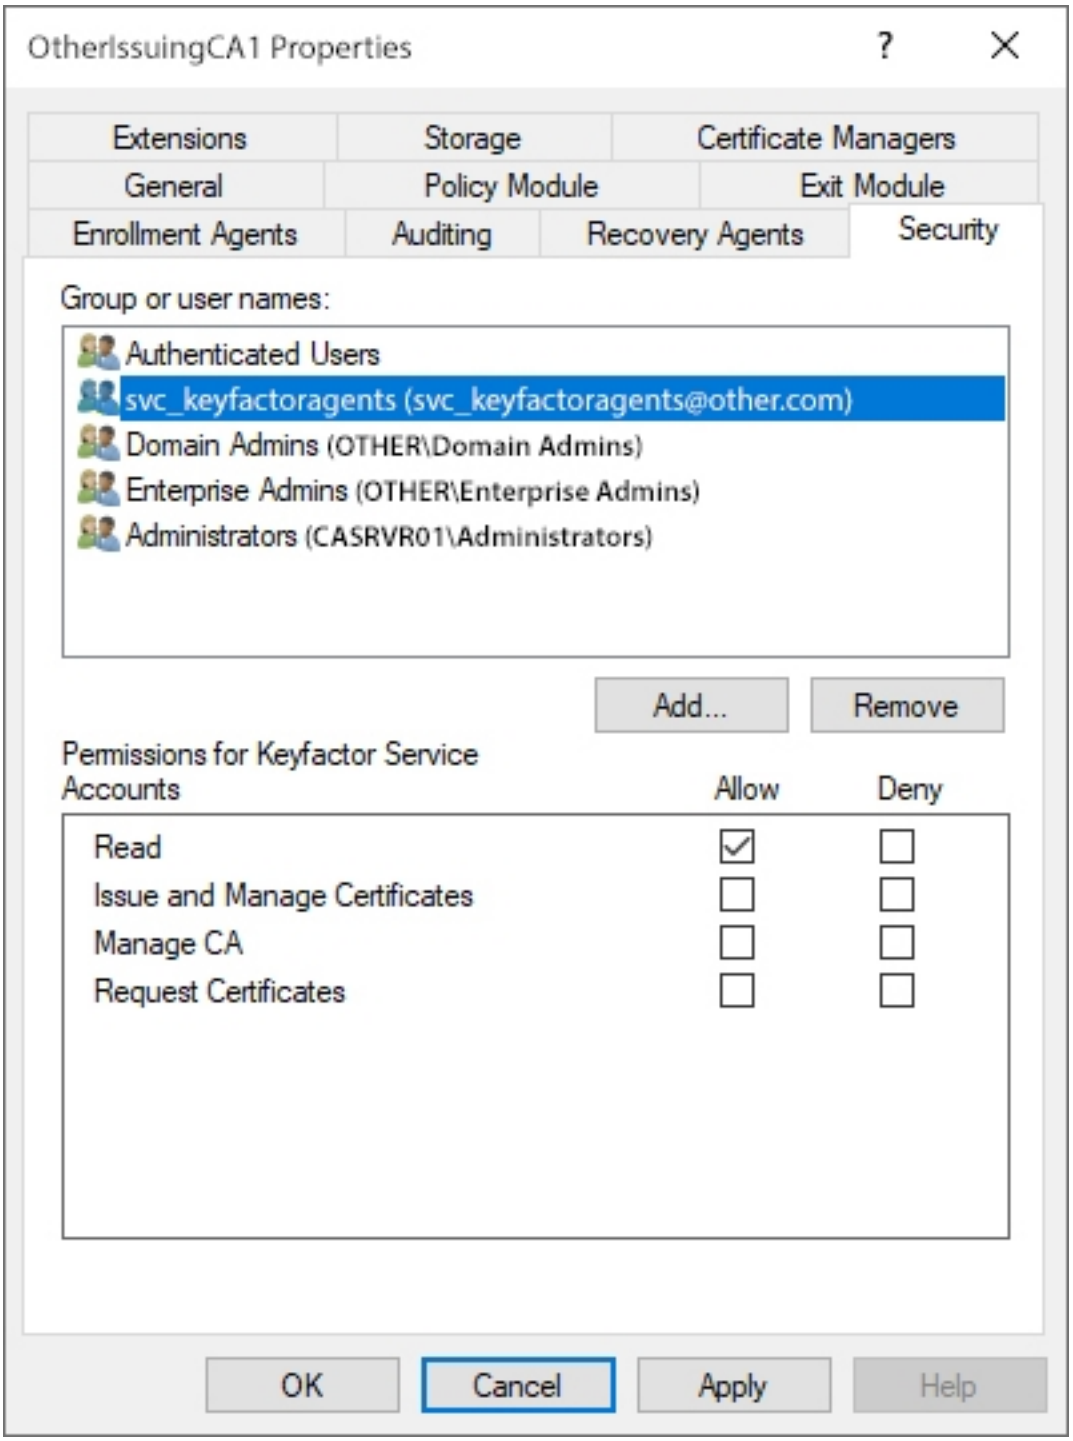

Figure 528: CA Permissions

5.2.1.5 Acquire a Certificate for Client Certificate Authentication (Optional)

The Keyfactor Universal Orchestrator supports client certificate authentication to allow you to authenticate via client certificates from individual orchestrator machines to either a centralized proxy, such as a network load balancer, which would in turn authenticate to the Keyfactor Command server using either a username and password that was stored securely on the proxy or another client certificate, or directly using IIS on the Keyfactor Command to manage the certificate authentication and Active Directory to manage the mapping of client certificates to service accounts. The proxy approach allows orchestrator credentials to be assigned and managed outside the Active Directory forest in which Keyfactor Command is installed. The web proxy's job is to confirm the validity of the certificate and to provide Active Directory credentials known to Keyfactor Command (if configured in this manner). Typically the proxy would be configured to accept all certificates issued from a given PKI implementation—even a PKI that is unknown to the Keyfactor Command Active Directory forest—thus delegating orchestrator access control to that PKI. For more information, see:

- Appendix - Set up the Universal Orchestrator to Use Client Certificate Authentication via a Reverse Proxy: Citrix ADC on page 2462
- Appendix - Set up the Universal Orchestrator to Use Client Certificate Authentication with Certificates Stored in Active Directory on page 2474

Important: The Universal Orchestrator supports automated client certificate renewal using an extension point interface on the orchestrator that can be implemented by the end-user. The custom extension will generate a CSR with private key and submit the CSR to Keyfactor Command for enrollment. Keyfactor Command will return the certificate to the orchestrator, which will pair it with its private key and use that certificate for authentication. See Register a Client Certificate Renewal Extension on page 2406 for more information.

There are several situations in which using certificate authentication for the Universal Orchestrator may be helpful, including:

- Scale—To allow orchestrator numbers to scale (e.g. the IoT case) where it isn't practical to have a unique Active Directory account for each orchestrator.
- Untrusted Environments—To support environments (e.g. a "hostile" network) where policy doesn't allow the password for an Active Directory account to be stored on the orchestrator.

The certificate that the Universal Orchestrator uses for authentication needs:

- An extended key usage (EKU) of Client Authentication

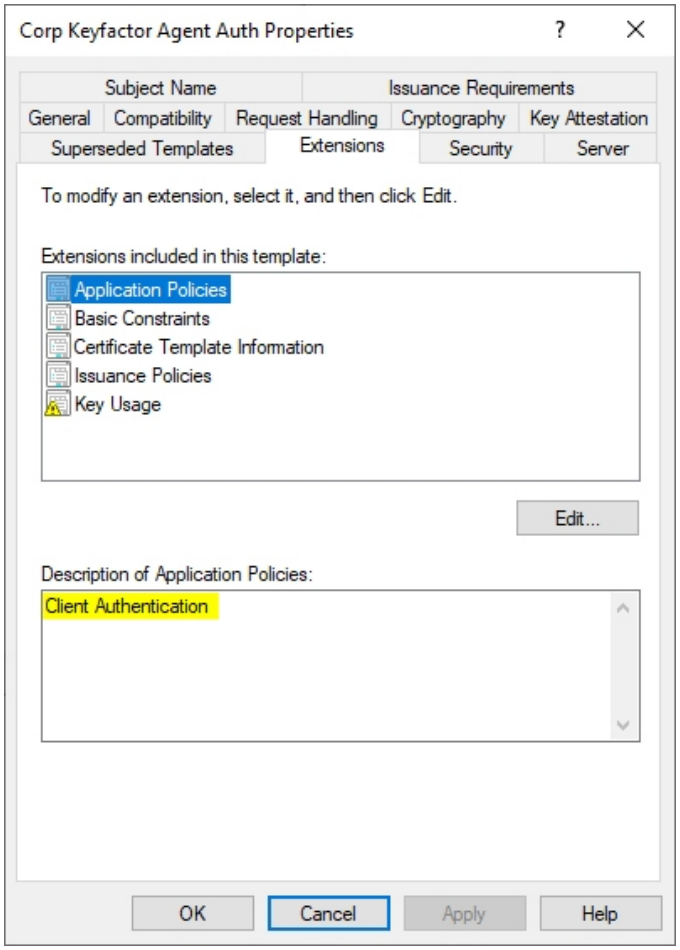

Figure 529: Microsoft Certificate Template Application Policies for Client Authentication Certificate

- A key usage that includes Digital Signature

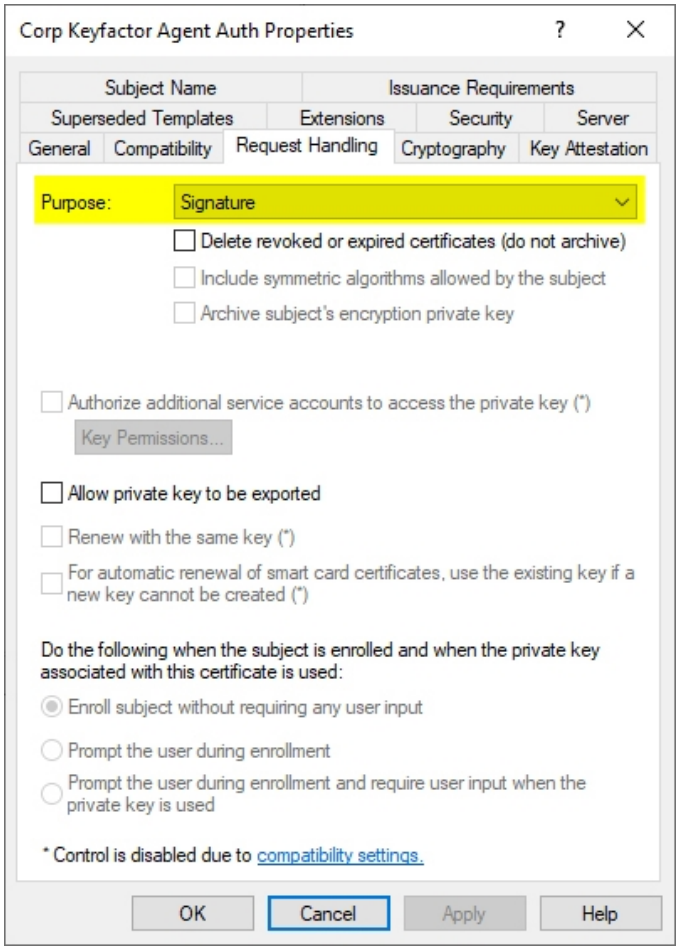

Figure 530: Microsoft Certificate Template Request Handling for Client Authentication Certificate

On Windows servers, the certificate may be referenced either as a PKCS12 file stored in the file system or may be place either in the local machine's personal store (*My*), or, if you opt to run the Universal Orchestrator service as a domain service account rather than the default of *Network Service*, in the personal store of the Universal Orchestrator service account user. If you opt to place the certificate in the local machine store, you need to grant the service account under which the Universal Orchestrator service will run (including *Network Service* if you will use this option) read permissions to the private key of the certificate. If you opt to place the certificate in the personal store of the Universal Orchestrator service account user, it also needs to be placed in the personal store of the user running the installation for the duration of the installation to allow it to be read during initial configuration. It may be removed from the installing user's store after installation is complete.

On Linux servers, the certificate is referenced as a PKCS12 file stored in the file system.

To acquire a certificate for use by the Universal Orchestrator using a Microsoft CA, first create a template using the appropriate configurations as described above and make it available for enrollment on the CA from which you will request the certificate. The simplest way to acquire a certificate as a PKCS12 file for either Linux or Windows use is

with PFX enrollment in Keyfactor Command. There are multiple ways to acquire a certificate and place it in the machine store on the Windows server where the Universal Orchestrator will be installed, including:

- Enroll through the Microsoft certificates MMC.
- Generate a CSR through the Microsoft certificates MMC and take the CSR to Keyfactor Command to issue a certificate using the CSR enrollment option in the Keyfactor Command Management Portal. You will need to return to the Microsoft certificates MMC to marry the certificate with the private key.
- Enroll for a certificate through Keyfactor Command using the PFX enrollment method and deploy it to the certificate store using an already installed Universal Orchestrator or Windows Orchestrator managing the store as an IIS store.
- Enroll using the command-line certreq command with a request.inf file on the Universal Orchestrator server.

Several of the above methods can also be used if you opt to enroll into the Universal Orchestrator service account user's personal store, though this option requires a few extra steps.

To enroll for a certificate using the certificates MMC into the local machine store:

1. On the Universal Orchestrator machine, do one of following:
    - Using the GUI:
        a. Open an empty instance of the Microsoft Management Console (MMC).
        b. Choose **File->Add/Remove Snap-in…**.
        c. In the *Available snap-ins* column, highlight **Certificates** and click **Add**.
        d. In the Certificates snap-in popup, choose the radio button for Computer account, click **Next**, accept the default of Local computer, and click **Finish**.
        e. Click **OK** to close the Add or Remove Snap-ins dialog.
    - Using the command line:
        a. Open a command prompt using the "Run as administrator" option.
        b. Within the command prompt type the following to open the certificates MMC:
        ```
        certlm.msc
        ```
2. Drill down to the Personal folder under **Certificates** for the Local Computer, right-click, and choose **All Tasks->Request New Certificate…**.
3. Follow the certificate enrollment wizard, selecting the template you created or identified for use for this purpose, and providing any required information.
4. When the enrollment completes, locate the certificate in the Personal store (you may need to refresh), highlight it, and choose **All Tasks->Manage Private Keys…**.
5. In the Permissions for private keys dialog, click **Add**, add the Universal Orchestrator service account—the account under which the Universal Orchestrator is running (created as per Create Service Accounts for the Universal Orchestrator on page 2362)—and grant that service account **Read** but not **Full control** permissions. Click **OK** to save.

5.2.1.6 Upgrading the Universal Orchestrator

There are two possible paths for upgrading from an earlier implementation of the Keyfactor Universal Orchestrator to a newer implementation:

- If your newer orchestrator will be installed in the same path as the older orchestrator, you may install the newer orchestrator over the older orchestrator using the *-Force* (Windows) or *--force* (Linux) option to overwrite the existing implementation.
- You may uninstall the older implementation using the provided uninstall script (uninstall.ps1 on Windows or uninstall.sh on Linux) and install the newer version using the standard installation steps (see Install the Universal Orchestrator on Windows below or Install the Universal Orchestrator on Linux on page 2382).

If you have an existing instance of the Keyfactor Windows Orchestrator and wish to migrate to the Keyfactor Universal Orchestrator, you may either install the two orchestrators side-by-side and then uninstall the Keyfactor Windows Orchestrator or uninstall the Keyfactor Windows Orchestrator and then install the Keyfactor Universal Orchestrator.

Important: Before following any of these upgrade paths, be sure to save off a copy of any custom extensions for the Keyfactor Universal Orchestrator (found in C:\Program Files\Keyfactor\Keyfactor Orchestrator\extensions by default) or plugins for the Keyfactor Windows Orchestrator (found in C:\Program Files\Keyfactor\Keyfactor Windows Orchestrator\plugins by default) before beginning the upgrade. You will need to put these back into place after the upgrade.

5.2.2 Install the Universal Orchestrator on Windows

To install the Keyfactor Universal Orchestrator on Windows, copy the zip file containing installation files to a temporary working directory on the Windows server and unzip it.

Note: In some instances, downloading a compressed file on Windows can cause the file to be marked as *blocked*. If you unzip a blocked file and proceed with the installation, the installation may fail with an error about missing files or dependencies (e.g. "Could not load file or assembly [filename] or one of its dependencies..."). Before beginning the installation, check the zip file *before* unzipping it to confirm that it is not blocked and unblock it if it is blocked.

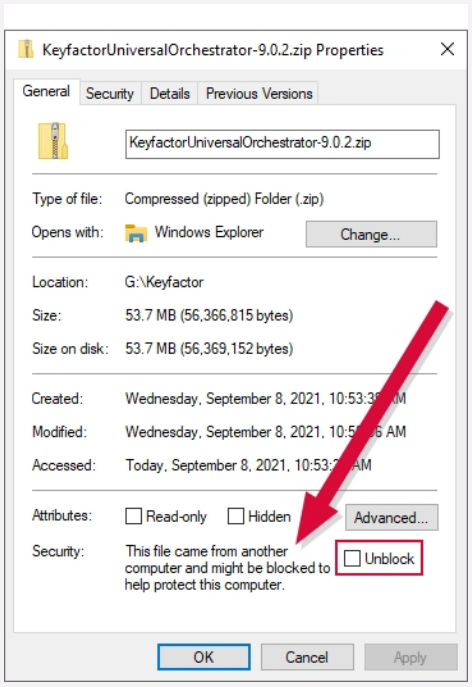

Figure 531: Installation Files Blocked after Download

To begin the installation:

1. On the Windows machine on which you wish to install the orchestrator, open a PowerShell window using the "Run as Administrator" option and change to the temporary directory where you placed the installation files.

2. In the PowerShell window, run the following commands to populate a variable with the user credentials for the Keyfactor Command connect service account (see Create Service Accounts for the Universal Orchestrator on page 2362) and, if you plan to run the orchestrator as a standard custom service account (rather than the default of Network Service), populate a variable with the user credentials for the Universal Orchestrator service account:

   ```
   $credKeyfactor = Get-Credential
   $credService = Get-Credential
   ```

   Enter the appropriate username and password when prompted. In these examples, *credKeyfactor* is used for the for the Keyfactor Command connect service account that the orchestrator uses to connect to Keyfactor Command and *credService* is used for the Universal Orchestrator service account that the service runs as. User-names should be given in DOMAIN\username format.

   To avoid being prompted for credentials while using Network Service to run the local service:

   ```
   $keyfactorUser = "DOMAIN\mykeyfactorconnectusername"
   $keyfactorPassword = "MySecurePassword"
   $secKeyfactorPassword = ConvertTo-SecureString $keyfactorPassword -AsPlainText -Force
   $credKeyfactor = New-Object System.Management.Automation.PSCredential ($keyfactorUser,
   $secKeyfactorPassword)
   ```

To avoid being prompted for credentials while using a standard AD service account to run the local service:

```
$serviceUser = "DOMAIN\myserviceusername"
$keyfactorUser = "DOMAIN\mykeyfactorconnectusername"
$keyfactorPassword = "MyFirstSecurePassword"
$servicePassword = "MySecondSecurePassword"
$secKeyfactorPassword = ConvertTo-SecureString $keyfactorPassword -AsPlainText -Force
$secServicePassword = ConvertTo-SecureString $servicePassword -AsPlainText -Force
$credKeyfactor = New-Object System.Management.Automation.PSCredential ($keyfactorUser,
$secKeyfactorPassword)
$credService = New-Object System.Management.Automation.PSCredential ($serviceUser,
$secServicePassword)
```

To avoid being prompted for credentials while using a group managed service account (gMSA) to run the local service:

```
$serviceUser = "DOMAIN\myGMSAserviceusername$"
$keyfactorUser = "DOMAIN\mykeyfactorconnectusername"
$keyfactorPassword = "MySecurePassword"
$secKeyfactorPassword = ConvertTo-SecureString $keyfactorPassword -AsPlainText -Force
$credKeyfactor = New-Object System.Management.Automation.PSCredential ($keyfactorUser,
$secKeyfactorPassword)
$credService = New-Object System.Management.Automation.PSCredential ($serviceUser,(New-
Object System.Security.SecureString))
```

Tip: In some cases, you may be using the same service account for both the Universal Orchestrator service account role and the Keyfactor Command connect service account role. If this is the case, you may use a single variable for both passwords in the next step.

Note: Group managed service accounts are not supported for use in making the connection to Keyfactor Command.

3. In the PowerShell window, run the install.ps1 script using the following syntax to begin the installation:

-URL (Required)

This is the URL to the Agent Services endpoint on the Keyfactor Command server running the Keyfactor Command Agent Services role. If you installed all the Keyfactor Command server roles together, this is the URL for your Keyfactor Command server with /KeyfactorAgents after the server's IP or FQDN (e.g. https://keyfactor.keyexample.com/KeyfactorAgents). If you choose to use SSL to connect to the Keyfactor Command server, you'll need to enter a URL that contains a hostname that is found in the SSL certificate.

This parameter is **required**.

Note: If you've opted to use client certificate authentication for the orchestrator, the value you use for the **URL** will vary depending on the method you select to implement client certificate authentication. You may choose to route client certificate authentication through a proxy (see Appendix - Set up the Universal Orchestrator to Use Client Certificate Authentication via a Reverse Proxy: Citrix ADC on page 2462), in which case you would use the proxy server name here (whatever name you're using to route traffic through the proxy). You may choose to publish client certificates to Active Directory and access the Keyfactor Command server directly (see Appendix - Set up the Universal Orchestrator to Use Client Certificate Authentication with Certificates Stored in Active Directory on page 2474), in which case you would use the Keyfactor Command server name here.

Tip: If your Keyfactor Command server was configured with an alternate virtual directory for the Keyfactor Command Agents Services endpoint, you will need to enter that in the URL rather than /KeyfactorAgents.

Client Authentication Parameters (Required)

The Keyfactor Universal Orchestrator supports authenticating to the Keyfactor Command server using either standard authentication (Basic authentication) or client certificate authentication. When you configure the orchestrator, you should configure either standard authentication (*WebCredential*) and provide a username and password as a PSCredential object or configure client certificate authentication (either *ClientCertificateThumbprint* or *ClientCertificate* and *ClientCertificatePassword*). You cannot configure both types of authentication together.

One of the following authentication methods is **required**:

- *WebCredential*
- *ClientCertificateThumbprint*
- *ClientCertificate* and *ClientCertificatePassword*

Important: Choosing a client certificate authentication method for the orchestrator may require additional configuration on your Keyfactor Command server. For more information, see Appendix - Set up the Universal Orchestrator to Use Client Certificate Authentication with Certificates Stored in Active Directory on page 2474, Appendix - Set up the Universal Orchestrator to Use Client Certificate Authentication via a Reverse Proxy: Citrix ADC on page 2462, and Install the Main Keyfactor Command Components on the Keyfactor Command Server(s) on page 2253 in the *Keyfactor Command Server Installation Guide*.

Tip: For information about rotating passwords and client authentication certificates, see Change Service Account Passwords on page 2402.

-WebCredential (Required with Basic Authentication)

This is the credential object of the Keyfactor Command connect service account that the orchestrator uses to communicate with Keyfactor Command that you created as per Create Service Accounts for the Universal Orchestrator on page 2362. It is provided as a PSCredential object.

This parameter is **required** if Basic authentication will be used.

This parameter cannot be used in conjunction with the *ClientCertificateThumbprint*, *ClientCertificate*, or *ClientCertificatePassword* parameter.

-ClientCertificateThumbprint

The thumbprint of the client authentication certificate used to authenticate to Keyfactor Command created as per Acquire a Certificate for Client Certificate Authentication (Optional) on page 2368. The certificate must have a Client Authentication EKU, have a private key readable by the account under which the Universal Orchestrator service will run (see -ServiceCredential on the next page), and be located in either the orchestrator local machine's personal certificate store (*My*) or the Universal Orchestrator service account user's (see -ServiceCredential on the next page) personal certificate store. If the certificate is stored in the local machine's store, the Universal Orchestrator service account user must be granted permissions to read the private key of the certificate (see the final steps under Acquire a Certificate for Client Certificate Authentication (Optional) on page 2368).

You may specify either the thumbprint of the certificate with the *ClientCertificateThumbprint* parameter or specify a path and password to a PKCS12 file containing the certificate on the orchestrator using *ClientCertificate* and *ClientCertificatePassword*. You do not need to specify both a thumbprint and a PKCS12 file; if you do, the certificate stores will take precedence.

This parameter cannot be used in conjunction with the *WebCredential* parameter.

-ClientCertificate

The path and file name on the orchestrator of a PKCS12 file containing the client authentication certificate used to authenticate to Keyfactor Command created as per Acquire a Certificate for Client Certificate Authentication (Optional) on page 2368. The certificate must have a Client Authentication EKU.

The account under which the Universal Orchestrator service will run (see -ServiceCredential on the next page) needs read and write permissions on the PKCS12 file you specify with this parameter.

Specifying this parameter **requires** that *ClientCertificatePassword* also be specified.

You may specify either the thumbprint of the certificate with the *ClientCertificateThumbprint* parameter or specify a path and password to a PKCS12 file containing the certificate on the orchestrator using *ClientCertificate* and *ClientCertificatePassword*. You do not need to specify both a thumbprint and a PKCS12 file; if you do, the certificate stores will take precedence.

This parameter cannot be used in conjunction with the *WebCredential* parameter.

-ClientCertificatePassword

The password for the PKCS12 file specified with the ClientCertificate parameter.

Specifying this parameter **requires** that *ClientCertificate* also be specified.

This parameter cannot be used in conjunction with the *WebCredential* parameter.

-Source

Specify this parameter to point to a directory containing the installation files other than the directory in which the install.ps1 file is found. This parameter is used primarily if a copy of the install.ps1 file is made in an alternate directory, updated with some customizations, and then used for installation without being copied back to the directory where the remaining installation files are located.

-Destination

This parameter specifies a location in which to install the orchestrator that is other than the default. The default installation location is:

```
C:\Program Files\Keyfactor\Keyfactor Orchestrator
```

This parameter cannot be used in conjunction with the *InPlace* parameter.

-InPlace

This parameter is used to indicate that the installation should occur in the current directory where the install files are located and no files should be copied to another location on the machine.

This parameter cannot be used in conjunction with the *Destination* parameter. This parameter is only supported if the *Capabilities* parameter is set to *all*.

-ServiceSuffix

This parameter is used to add a suffix to the root service name of *KeyfactorOrchestrator* (e.g. *Instance1* for a resulting service name of *KeyfactorOrchestrator-Instance1*). This is used primarily for implementations where the orchestrator will be installed multiple times on the same server.

This parameter cannot be used in conjunction with the *NoService* parameter.

If this parameter is not specified, the default service name of *KeyfactorOrchestrator-Default* will be used—with a display name of *Keyfactor Orchestrator Service (Default)*.

-ServiceCredential

This is the credential object of the Universal Orchestrator service account the orchestrator service will run as (see Create Service Accounts for the Universal Orchestrator on page 2362. It is provided as a PSCredential object.

This parameter cannot be used in conjunction with the *NoService* parameter.

If this parameter is not specified, the built-in Network Service account will be used.

-NoService

This parameter is used to indicate that no Windows service should be created. The orchestrator will be installed but will need to be started manually or added as a service at a later time.

This parameter cannot be used in conjunction with the *ServiceSuffix* or *ServiceCredential* parameter.

-OrchestratorName

Specifying this parameter allows you to override the name the orchestrator would by default use to register itself in Keyfactor Command.

By default, the orchestrator uses the value of the COMPUTERNAME environment variable.

-Capabilities

This parameter is used to specify the capabilities the orchestrator will support if a capability set other than the default set is desired. Supported options are:

- all

  All the capabilities supported by the orchestrator will be enabled and reported to Keyfactor Command.

- none

  The orchestrator will be installed with no capabilities and will not be registered with Keyfactor Command. This is primarily used for implementations that will support only custom capabilities (see Installing Custom-Built Extensions on page 2392 and Configuring Script-Based Certificate Store Jobs on page 2395).

- ssl

  Only the SSL discovery and monitoring capability will be enabled and reported to Keyfactor Command.

If the *InPlace* parameter is specified, this parameter must be set to *all*.

If this parameter is not specified, the default set of capabilities for the orchestrator will be used. For the Universal Orchestrator, the default capability set is *IIS*, *CA*, *FTP* and *LOG* (log fetching).

One installation of the orchestrator can be enabled with multiple capabilities to perform more than one function, but there are best practices for locating orchestrators that should be considered. For example, Keyfactor recommends against performing the SSL discovery and monitoring function using an orchestrator installed on the main Keyfactor Command server due to the resource requirements of this function and against using the same orchestrator for the SSL function and other functions, again due to the resource requirements. The CA management function is typically used on remote servers and not collocated with other orchestrator functions.

-Force

Specifying this parameter causes the installation to warn and continue on certain potential problems, including:

- A service with either the default service name or the service name specified with the *ServiceSuffix* parameter already exists. The service will be overwritten if *Force* is specified.
- Either the default installation location or the location specified with the *Location* parameter is not empty. The install will occur to the specified or default location anyway and files may be overwritten if *Force* is specified.

If this parameter is not specified and any of these problems are encountered, the installation will terminate prematurely.

Installation example with expected output using basic authentication (rather than a client certificate) and Network Service to run the local service:

```
$keyfactorUser = "KEYEXAMPLE\svc_kyforch1"
$keyfactorPassword = "MySecurePassword123!"
$secKeyfactorPassword = ConvertTo-SecureString $keyfactorPassword -AsPlainText -Force
$credKeyfactor = New-Object System.Management.Automation.PSCredential ($keyfactorUser, $secKey-
factorPassword)

.\install.ps1 -URL https://keyfactor.keyexample.com/KeyfactorAgents -WebCredential $credKeyfactor
-OrchestratorName websrvr42-IIS.keyexample.com -Capabilities all

Copying files
Setting configuration data
Installing Windows Service
Granting necessary file permissions to NT AUTHORITY\NETWORK SERVICE for configuration file
Starting service KeyfactorOrchestrator-Default
```

Installation example with expected output using basic authentication (rather than a client certificate) and a standard AD service account to run the local service:

```
$serviceUser = "KEYEXAMPLE\svc_kyforch1"
$keyfactorUser = "KEYEXAMPLE\svc_kyforch2"
$servicePassword = "MyFirstSecurePassword123!"
$keyfactorPassword = "MySecondSecurePassword456#"
$secServicePassword = ConvertTo-SecureString $servicePassword -AsPlainText -Force
$secKeyfactorPassword = ConvertTo-SecureString $keyfactorPassword -AsPlainText -Force
$credService = New-Object System.Management.Automation.PSCredential ($serviceUser, $secSer-
vicePassword)
$credKeyfactor = New-Object System.Management.Automation.PSCredential ($keyfactorUser,
```

```
$secKeyfactorPassword)

.\install.ps1 -URL https://keyfactor.keyexample.com/KeyfactorAgents -WebCredential $credKeyfactor
-ServiceCredential $credService -OrchestratorName websrvr42-IIS.keyexample.com -Capabilities all

Copying files
Setting configuration data
Installing Windows Service
Granting necessary file permissions to KEYEXAMPLE\svc_kyforch1 for configuration file
Granting Log on as a Service permission to KEYEXAMPLE\svc_kyforch1
Starting service KeyfactorOrchestrator-Default
```

Installation example with expected output using basic authentication (rather than a client certificate) and an AD gMSA to run the local service:

```
$serviceUser = "KEYEXAMPLE\GMSA_kyforch$"
$keyfactorUser = "KEYEXAMPLE\svc_kyforch"
$keyfactorPassword = "MySecurePassword123!"
$secKeyfactorPassword = ConvertTo-SecureString $keyfactorPassword -AsPlainText -Force
$credService = New-Object System.Management.Automation.PSCredential ($serviceUser,(New-Object
System.Security.SecureString))
$credKeyfactor = New-Object System.Management.Automation.PSCredential ($keyfactorUser, $secKey-
factorPassword)

.\install.ps1 -URL https://keyfactor.keyexample.com/KeyfactorAgents -WebCredential $credKeyfactor
-ServiceCredential $credService -OrchestratorName websrvr42-IIS.keyexample.com -Capabilities all

Copying files
Setting configuration data
Installing Windows Service
Granting necessary file permissions to KEYEXAMPLE\GMSA_kyforch$ for configuration file
Granting Log on as a Service permission to KEYEXAMPLE\GMSA_kyforch$
Starting service KeyfactorOrchestrator-Default
```

Important: Prior to using a gMSA in the installation, you need to have installed the account on the Universal Orchestrator server using the *Install-ADServiceAccount* PowerShell command. For example:

```
Install-ADServiceAccount -Identity GMSA_kyforch$
```

This requires the *Active Directory module for Windows PowerShell*, which is installed as a feature as part of the *Remote Server Administrator Tools*.

Installation example with expected output using client certificate authentication with the certificate stored in the local machine store:

```
$serviceUser = "KEYEXAMPLE\svc_kyforch"
$servicePassword = "MySecurePassword123!"
$secServicePassword = ConvertTo-SecureString $servicePassword -AsPlainText -Force
$credService = New-Object System.Management.Automation.PSCredential ($serviceUser, $secSer-
vicePassword)

.\install.ps1 -URL https://keyfactor.keyexample.com/KeyfactorAgents -ClientCertificateThumbprint
29b21df7403b4afe6daf44762e5c47fb73c07ce7 -ServiceCredential $credService -OrchestratorName
websrvr42-IIS.keyexample.com -Capabilities all

Copying files
Setting configuration data
Installing Windows Service
Granting necessary file permissions to KEYEXAMPLE\svc_kyforch for configuration file
Granting Log on as a Service permission to KEYEXAMPLE\svc_kyforch
Starting service KeyfactorOrchestrator-Default
```

Tip: The client certificate authentication example shown here references a certificate stored in the local machine store. Because of this, the service account that will run the Universal Orchestrator service needs to be granted permissions to read the private key of the certificate before the installation is run. If the certificate had been acquired into the Universal Orchestrator service account user's personal store rather than the local machine store, the step of granting private key read permissions would not have been necessary.

Installation example with expected output using client certificate authentication with the certificate stored as a file:

```
.\install.ps1 -URL https://keyfactor.keyexample.com/KeyfactorAgents -ClientCertificate
C:\Certs\kyforch.pfx -ClientCertificatePassword MySecurePassword123! -OrchestratorName websrvr42-
IIS.keyexample.com -Capabilities all

Copying files
Setting configuration data
Installing Windows Service
Granting necessary file permissions to KEYEXAMPLE\svc_kyforch for configuration file
Granting Log on as a Service permission to KEYEXAMPLE\svc_kyforch
Starting service KeyfactorOrchestrator-Default
```

Tip: The client certificate authentication example shown here does not use the -ServiceCredential parameter. This will cause the Universal Orchestrator service to run as Network Service. If you prefer to run the service as a domain service account, you will need to include the -ServiceCredential parameter and specify the PSCredential value for the service credentials appropriately, as shown in the

previous examples.
Network Service will need to be granted read and write permissions on the PFX file before the script is executed.

4. Review the output from the installation to confirm that no errors have occurred.

The script creates a directory, C:\Program Files\Keyfactor\Keyfactor Orchestrator by default, and places the orchestrator files in this directory. Log files are found in C:\Program Files\Keyfactor\Keyfactor Orchestrator\logs by default, though this is configurable (see Configure Logging for the Universal Orchestrator on page 2398).

The orchestrator service, by default given a display name of *Keyfactor Orchestrator Service (Default)*, should be automatically started at the conclusion of the install and configured to restart on reboot unless you have selected the *NoService* parameter.

Tip: Once the installation of the orchestrator is complete, you need to use the Keyfactor Command Management Portal to approve the orchestrator and configure certificate stores or SSL jobs as per the *Keyfactor Command Reference Guide*:

- Approving or Disapproving Orchestrators on page 459
- Certificate Store Operations on page 363
- SSL Discovery on page 418

If you've opted to enable remote CA management for the orchestrator, further configuration is needed (see Configure the Universal Orchestrator for Remote CA Management on page 2390).

5.2.3 Install the Universal Orchestrator on Linux

To install the Keyfactor Universal Orchestrator on Linux, copy the zip file containing installation files to a temporary working directory on the Linux server and unzip it.

To begin the installation:

1. On the Linux machine on which you wish to install the orchestrator, in a command shell change to the temporary directory where you placed the installation files.

2. Use the chmod command to make the install.sh script file executable. The file ships in a non-executable state to avoid accidental execution. For example:

   ```
   sudo chmod +x install.sh
   ```

3. In the command shell, run the install.sh script as root using the following syntax to begin the installation:

   ### --url

   This is the URL to the Agent Services endpoint on the Keyfactor Command server running the Keyfactor Command Agent Services role, which is installed as part of the Keyfactor Command Services role. If you

installed all the Keyfactor Command server roles together, this is the URL for your Keyfactor Command server with /KeyfactorAgents after the server's IP or FQDN (e.g. https://key-factor.keyexample.com/KeyfactorAgents). If you choose to use SSL to connect to the Keyfactor Command server, you'll need to enter a URL that contains a hostname that is found in the SSL certificate.

This parameter is **required**.

Tip: If your Keyfactor Command server was configured with an alternate virtual directory for the Keyfactor Command Agents Services endpoint, you will need to enter that in the URL rather than /Key-factorAgents.

Client Authentication Parameters

The Keyfactor Universal Orchestrator supports authenticating to the Keyfactor Command server using either standard authentication (Basic authentication) or client certificate authentication. When you configure the orchestrator, you should configure either standard authentication (*username* and *password*) or configure client certificate authentication (*client-auth-certificate* and *client-auth-certificate-password*). You cannot configure both types of authentication together.

One of the following authentication methods is **required**:

- *username* and *password*
- *client-auth-certificate* and *client-auth-certificate-password*

Important: Choosing to use client certificate authentication for the orchestrator may require additional configuration on your Keyfactor Command server. For more information, see Install the Main Keyfactor Command Components on the Keyfactor Command Server(s) on page 2253 in the *Keyfactor Command Server Installation Guide* and Appendix - Set up the Universal Orchestrator to Use Client Certificate Authentication with Certificates Stored in Active Directory on page 2474, Appendix - Set up the Universal Orchestrator to Use Client Certificate Authentication via a Reverse Proxy: Citrix ADC on page 2462.

Tip: For information about rotating passwords and client authentication certificates, see Change Service Account Passwords on page 2402.

--username

This is the Keyfactor Command connect service account that the orchestrator uses to communicate with Keyfactor Command that you created as per Create Service Accounts for the Universal Orchestrator on page 2362. It may be entered either as username@domain (e.g. svc_kyforch@keyexample.com) or DOMAIN\\username (e.g. KEYEXAMPLE\\svc_kyforch).

This parameter is **required** if Basic authentication will be used.

This parameter cannot be used in conjunction with the *client-auth-certificate* and *client-auth-certificate-password* parameters.

--password

This is the password for the Keyfactor Command connect service account that the orchestrator uses to communicate with Keyfactor Command specified with the *username* parameter.

Warning: The password for the Keyfactor Command connect service account is stored in clear text in the orchestratorsecrets.json file in the configuration directory under the installation directory for the orchestrator. By default, this file is granted read/write permissions for the Universal Orchestrator service account running the service on the Linux machine (*keyfactor-orchestrator* by default) and no permissions for any other users. Access to this file should be strictly controlled.
If you prefer to avoid the use of a password in a file, consider using client certificate authentication.

This parameter is **required** if the *username* parameter is specified.

Tip: If you prefer to avoid providing the password at the command line (and storing it in command history), use an input file instead as follows:

a. Create a file that contains just your password. For example:
```
vi my_password_file
```

b. When using the password parameter, reference the file. For example:
```
--password $(cat my_password_file)
```

c. Delete the password file after the install is complete. For example:
```
rm my_password_file
```

--client-auth-certificate

The path and file name on the orchestrator of a PKCS12 file containing the client authentication certificate used to authenticate to Keyfactor Command created as per Acquire a Certificate for Client Certificate Authentication (Optional) on page 2368. The certificate must have a Client Authentication EKU.

The account under which the Universal Orchestrator service will run (see --service-user on page 2386) needs read and write permissions on the PKCS12 file you specify with this parameter.

Specifying this parameter **requires** that *client-auth-certificate-password* also be specified.

This parameter cannot be used in conjunction with the *username* and *password* parameters.

--client-auth-certificate-password

The password for the PKCS12 file specified with the *client-auth-certificate* parameter.

Specifying this parameter **requires** that *client-auth-certificate* also be specified.

This parameter cannot be used in conjunction with the *username* and *password* parameters.

Tip: If you prefer to avoid providing the password for the certificate file at the command line (and storing it in command history), use an input file instead as follows:

a. Create a file that contains just your password. For example:
```
vi cert_password_file
```

b. When using the password parameter, reference the file. For example:
```
--password $(cat cert_password_file)
```

c. Delete the password file after the install is complete. For example:
```
rm cert_password_file
```

--source

Specify this parameter to point to a directory containing the installation files other than the directory in which the install.sh file is found. This parameter is used primarily if a copy of the install.sh file is made in an alternate directory, updated with some customizations, and then used for installation without being copied back to the directory where the remaining installation files are located.

--destination

This parameter specifies a location in which to install the orchestrator that is other than the default. The default installation location is:

```
/opt/keyfactor/orchestrator
```

This parameter cannot be used in conjunction with the *in-place* parameter.

--in-place

This parameter is used to indicate that the installation should occur in the current directory where the install files are located and no files should be copied to another location on the machine.

This parameter cannot be used in conjunction with the *destination* parameter. This parameter is only supported if the *capabilities* parameter is set to *all*.

--service-suffix

This parameter is used to add a suffix to the root service name of *keyfactor-orchestrator* (e.g. *instance1* for a resulting service name of *keyfactor-orchestrator-instance1*). This is used primarily for implementations where the orchestrator will be installed multiple times on the same server.

This parameter cannot be used in conjunction with the *no-service* parameter.

If this parameter is not specified, the default service name of *keyfactor-orchestrator-default* will be used.

--service-user

This is the local Linux Universal Orchestrator service account that the service will run as (see Create Service Accounts for the Universal Orchestrator on page 2362. It should be entered as just the user name. Entry of a password for this service account is not required. You may either create this account prior to running the installation script (or use an existing account) or use the *force* parameter to generate the account automatically during the installation process.

This parameter cannot be used in conjunction with the *no-service* parameter.

If this parameter is not specified, the default service account name of *keyfactor-orchestrator* will be used.

--no-service

This parameter is used to indicate that no service should be created and added to the server's service control manager. The orchestrator will be installed but will need to be started manually or added to the server's service control manager manually.

This parameter cannot be used in conjunction with the *service-suffix* or *service-user* parameter.

--orchestrator-name

Specifying this parameter allows you to override the name the orchestrator would by default use to register itself in Keyfactor Command.

By default, the orchestrator uses the results from a hostname lookup for the server's name.

--capabilities

This parameter is used to specify the capabilities the orchestrator will support if a capability set other than the default set is desired. Supported options are:

- all

  All the capabilities supported by the orchestrator will be enabled and reported to Keyfactor Command.

- none

  The orchestrator will be installed with no capabilities and will not be registered with Keyfactor Command. This is primarily used for implementations that will support only custom capabilities (see Installing Custom-Built Extensions on page 2392 and Configuring Script-Based Certificate Store Jobs on page 2395).

- ssl

  Only the SSL discovery and monitoring capability will be enabled and reported to Keyfactor Command.

If the *in-place* parameter is specified, this parameter must be set to *all*.

If this parameter is not specified, the default set of capabilities for the orchestrator will be used. For the Linux orchestrator, the default capability set is *FTP* and *LOG* (log fetching).

Important: The Linux orchestrator does not support the CA (remote CA management) or IIS (Windows server certificate store) capabilities due to the Windows-specific nature of the authentication requirements for these methods.

--force

Specifying this parameter causes the installation to warn and continue on certain potential problems, including:

- The local Universal Orchestrator service account does not exist. The default user will be created if *force* is specified.
- The appsettings.json file does not exist. A new one will be created if *force* is specified.
- A service with either the default service name or the service name specified with the *service-suffix* parameter already exists. The service will be overwritten if *force* is specified.
- Either the default installation location or the location specified with the *location* parameter is not empty. The install will occur to the specified or default location anyway and files may be overwritten if *force* is specified.

If this parameter is not specified and any of these problems are encountered, the installation will terminate prematurely. See also the *what-if* parameter.

--what-if

This parameter is used to test the installation command without actually installing in order to see any errors that might arise and correct them before installing.

Installation example with expected output using basic authentication:

```
vi my_password_file

sudo ./install.sh --url https://keyfactor.keyexample.com/KeyfactorAgents --username svc_
kyforch@keyexample.com --password $(cat my_password_file) --orchestrator-name appsrvr16-
ssl.keyexample.com --capabilities all --force

Creating user keyfactor-orchestrator
Copying files from /tmp/KeyfactorOrchestrator to /opt/keyfactor/orchestrator
Saving app settings
Setting file permissions
Installing systemd service keyfactor-orchestrator-default
Created symlink /etc/systemd/system/multi-user.target.wants/keyfactor-orchestrator-default.ser-
vice → /etc/systemd/system/keyfactor-orchestrator-default.service.
Starting systemd service keyfactor-orchestrator-default
```

Installation example with expected output using client certificate authentication:

```
vi cert_password_file

sudo ./install.sh --url https://keyfactor.keyexample.com/KeyfactorAgents --client-auth-certi-
ficate /opt/certs/kyforch.p12 --client-auth-certificate-password $(cat cert_password_file) --
orchestrator-name appsrvr16-ssl.keyexample.com --capabilities all --force

Creating user keyfactor-orchestrator
Copying files from /tmp/KeyfactorOrchestrator to /opt/keyfactor/orchestrator
Saving app settings
Setting file permissions
Installing systemd service keyfactor-orchestrator-default
Created symlink /etc/systemd/system/multi-user.target.wants/keyfactor-orchestrator-default.ser-
vice → /etc/systemd/system/keyfactor-orchestrator-default.service.
Starting systemd service keyfactor-orchestrator-default
```

4. Review the output from the installation to confirm that no errors have occurred.

The script creates a directory, /opt/keyfactor/orchestrator by default, and places the orchestrator files in this directory. Log files are found in /opt/keyfactor/orchestrator/logs by default, though this is configurable (see Configure Logging for the Universal Orchestrator on page 2398).

The orchestrator service, by default named keyfactor-orchestrator-default.service, should be automatically started at the conclusion of the install and configured to restart on reboot unless you have selected the *no-service* parameter.

Tip: Once the installation of the orchestrator is complete, you need to use the Keyfactor Command Management Portal to approve the orchestrator and configure certificate stores or SSL jobs as per the *Keyfactor Command Reference Guide*:

- Approving or Disapproving Orchestrators on page 459
- Certificate Store Operations on page 363
- SSL Discovery on page 418

5.2.4 Optional Configuration

Once the installation is complete, the Keyfactor Universal Orchestrator should be running and ready to communicate with the Keyfactor Command server. The initial installation allows the orchestrator to register itself with Keyfactor Command and run jobs of the capability types configured during installation (after being approved in the Keyfactor Command Management Portal) unless you selected the NoService parameter.

This section details some post-install configuration steps that may need to be completed for some capabilities and some optional settings.

Important: Synchronization for the remote CA functionality of the orchestrator will not begin until you complete the configuration by making the appropriate configuration changes in the Keyfactor Command Management Portal. See Orchestrator Management on page 454 in the *Keyfactor Command Reference Guide* for instructions on approving the orchestrator in the Keyfactor Command Management Portal on the *Orchestrators->Management* page and Adding or Modifying a CA Record on page 311 in the *Keyfactor Command Reference Guide* for instructions on configuring certificate and template synchronization for remote CAs on the *Locations->Certificate Authorities* page.

5.2.4.1 Configure the Targets for IIS Management

This step only needs to be completed if you plan to use the Keyfactor Universal Orchestrator to manage Windows machine store certificates (IIS Certificate Store Inventory Reporting and IIS Certificate Store Management).

Permissions

On each target machine where you wish to manage the machine certificate store with the Universal Orchestrator, you need to grant the Active Directory service account under which the orchestrator is running sufficient permissions to read the local machine certificate store and, if you plan to deploy certificates to it using Keyfactor Command, write to it. This can be accomplished by adding the Universal Orchestrator service account to the local administrators group on each target machine.

PowerShell Remoting

The orchestrator uses PowerShell remoting to deliver certificates in PFX format to targets and bind certificates to IIS web sites. This includes certificates delivered directly from the PFX enrollment option of the Keyfactor Command Management Portal or Keyfactor API to targets. If you wish to use any of these features, you will need to make sure that each target machine on which you want to use one of these features is running at least PowerShell version 3 and that PowerShell remoting has been enabled. To check the PowerShell version on a given machine, open a PowerShell window, run the following command, and check the output CLRVersion:

```
$PSVersionTable
```

PowerShell version 3 is available for download from Microsoft.

To enable PowerShell remoting:

1. On the target machine, open a PowerShell window using the "Run as administrator" option.
2. On the target machine, run the following command to enable PowerShell remoting:
   ```
   Enable-PSRemoting
   ```
   Respond Yes to all the question prompts (or "A" for all).
3. On the target machine it may be necessary to run the following command to enable execution of unsigned local PowerShell scripts for some operating systems (e.g. Windows Server 2008 R2):
   ```
   Set-ExecutionPolicy RemoteSigned
   ```
4. To test the PowerShell remoting, on the Universal Orchestrator server, open a PowerShell window and run the following command (where TARGET_MACHINE is the FQDN of the target machine you wish to manage

with the orchestrator):

```
Enter-PSSession –ComputerName TARGET_MACHINE
```

Use the actual hostname of the target machine rather than a DNS alias (either "A" or CNAME records) when running this test. This is necessary because PowerShell remoting relies on Kerberos authentication, which requires that the target machine has a service principal name (SPN) in the HTTP/ format assigned to the target's machine account. This will be present by default (as part of the HOST/ format record) as long as the HTTP/ format SPN has not been manually assigned elsewhere. Using an alias gets into complexities of setting up appropriate SPNs and assuring that there are not duplicate SPNs in the environment.

You should be connected to the target machine and be able to execute PowerShell commands on the target machine.

Firewall Port Considerations

When you add an IIS certificate store in Keyfactor Command, the Universal Orchestrator uses the port for SMB (445) to communicate to the remote target hosting the IIS certificate store. Make sure that any firewalls between the Universal Orchestrator, Keyfactor Command, and the IIS target allow communications over port TCP 445.

5.2.4.2 Configure the Universal Orchestrator for Remote CA Management

If you've opted to enable the remote CA management functionality for the Keyfactor Universal Orchestrator, further configuration is needed on the orchestrator to configure the CA(s) that the orchestrator will manage.

To configure CAs for the orchestrator:

1. On the orchestrator, open a text editor (e.g. Notepad) using the "Run as administrator" option.
2. In the text editor, browse to open the *extensionoptions.json* file for the Universal Orchestrator. The file is located in the configuration directory within the install directory, which is the following directory by default:

   C:\Program Files\Keyfactor\Keyfactor Orchestrator\configuration

3. In the extensionoptions.json file, locate the CertificateAuthority section.

```
{
  "CertificateAuthority": {
    "BatchSize": 10000,
    "CacheHours": 3,
    "RecordCountLimit": 5000,
    "MaxErrorCount": 5,
    "AdditionalCertificateAuthoritiesAllowed": false,
    "CertificateAuthorities": [
      {
        "Forest": "keyother.com",
        "Hostname": "corpca01.keyother.com",
        "LogicalName": "KeyIssuing01"
      },
      {
        "Forest": "keyother.com",
        "Hostname": "corpca02.keyother.com",
        "LogicalName": "KeyIssuing02"
      }
    ]
  },
```

Figure 532: CA Configuration Settings

4. Either set the *AdditionalCertificateAuthoritiesAllowed* value to **true** or populate the *CertificateAuthorities* section with your CA information (see Table 768: Remote CA Configuration Parameters).
5. Save the file.
6. Restart the orchestrator service (see Start the Universal Orchestrator Service on page 2401).

Table 768: Remote CA Configuration Parameters

Parameter	Description
BatchSize	An integer that specifies the number of certificate cache records to read from the Keyfactor Command in each data retrieval batch. The default is 10,000. **Tip:** Certificate cache information from Keyfactor Command is retrieved from and stored on the orchestrator to allow the orchestrator to calculate which records represent changes and return only those to Keyfactor Command on requests from Keyfactor Command for CA synchronization.
CacheHours	An integer that specifies the number of hours for which to cache certificate information from Keyfactor Command on the orchestrator before clearing it. The default is 3.
RecordCountLimit	An integer that specifies the number of records to read from the CA(s) in each synchronization batch. The default is 5,000.
MaxErrorCount	An integer that specifies the number of times an attempt should be made to read records from the CA before the synchronization job ends with a failure. The default is 5.

<table>
<tr><th>Parameter</th><th>Description</th></tr>
<tr><td>AdditionalCertificateAuthoritiesAllowed</td><td>A Boolean that sets whether any CAs available to the orchestrator (to which the orchestrator has network access and sufficient permissions) should be considered as managed (True) or whether only those CAs specifically listed in the CertificateAuthorities parameter should be considered as managed (False). If you set this value to True, you do not need to populate the CertificateAuthorities value.</td></tr>
<tr><td>CertificateAuthorities</td><td>An array of the certificate authorities that should be considered managed by the orchestrator. The certificate authority information includes:
<table>
<tr><th>Parameter</th><th>Description</th></tr>
<tr><td>Forest</td><td>The name of the Active Directory forest in which the CA resides.</td></tr>
<tr><td>Hostname</td><td>The fully qualified domain name of the CA.</td></tr>
<tr><td>LogicalName</td><td>The logical name of the CA.</td></tr>
</table></td></tr>
</table>

5.2.4.3 Installing Custom-Built Extensions

Custom-built extensions for the Keyfactor Universal Orchestrator are generated using the Universal Orchestrator NuGet package. Custom-built extensions for certificate store jobs and custom jobs are both installed in the same way.

Once you have your custom-built extension ready, install it as follows:

1. On the Universal Orchestrator server, locate the extensions directory within the install directory. By default, this is:

   Windows: C:\Program Files\Keyfactor\Keyfactor Orchestrator\extensions
   Linux: /opt/keyfactor/orchestrator/extensions

2. Under the extensions directory, create a new directory with an appropriate name for your custom-built extension (e.g. MyExtension). This name is for reference only and does not need to match any names used elsewhere.

3. Place the DLL(s) created for your custom-built extension along with any other supporting files needed for the extension in the new directory.

4. In the directory for your custom-built extension, create a file called manifest.json if one has not been provided with the extension. The manifest.json file must be placed in the same directory as the DLL(s) for your extension.

5. Using a text editor, edit the manifest.json file and configure it appropriately for your application. Some things to keep in mind are:

- The opening and closing lines of the file must match those shown in red here:

```
{
   "extensions": {
      "Keyfactor.Orchestrators.Extensions.IOrchestratorJobExtension":
{
         "Custom.MyJob": {
            "assemblypath": "Keyfactor.Orchestrators.MyJob.dll",
            "TypeFullName": "Keyfactor.Orchestrators.MyJob.MyJobExtension"
         }
      }
   }
}
```

- Each customized section of the file starts with either a custom job reference (e.g. Custom.MyJob) or a certificate store reference (e.g. CertStores.MyStore.Inventory).

  Custom jobs (beginning *Custom*) correspond to custom job types created with the Keyfactor API *POST /JobTypes/Custom* method. For example, a custom job type with a *JobTypeName* of *MyJob* would appear in the file as *Custom.MyJob*.

  Certificate store jobs (beginning *CertStores*) correspond to certificate store types created with the Keyfactor API *POST /CertifiateStoreType* method (see POST Certificate Store Types on page 1247 in the *Keyfactor Web APIs Reference Guide*) or in the Keyfactor Command Management Portal (see Adding or Editing a Certificate Store Type on page 604 in the *Keyfactor Command Reference Guide*). For example, a certificate store type with a *Capability* of *MyStore* configured to do inventory, management and discovery, would have three separate sections in the file as *CertStores.MyStore.Inventory*, *CertStores.MyStore.Management*, and *CertStores.MyStore.Discovery*. An inventory section is required.
- The *assemblypath* referenced in each section points to the DLL in the extensions directory that corresponds to that job function. A single manifest file may include many different capabilities if the extension performs more than one type of job (e.g. inventory and management of certificates), such as is shown in the below example.
- The *TypeFullName* referenced in each section corresponds to the name of the type that resides inside of the DLL listed for the assembly path. A single manifest file may include many different capabilities if the extension performs more than one type of job (e.g. inventory and management of certificates), such as is shown in the below example.
- Each section may optionally have a *PreScript* reference, which points to a script file on the orchestrator machine that will run before the main job for the section executes.
  - For orchestrators installed on Windows, these will be PowerShell scripts. No special configuration is needed other than entry of a path to the PowerShell script in the *PreScript* field. The script may be placed anywhere on the orchestrator machine. The orchestrator will need read permissions to the script.
  - For orchestrators installed on Linux, these will be Bash scripts. In order to use a Bash script with the orchestrator, you must first register the Bash script driver in the appsettings.json file. This file is found in the Configuration directory. Edit the file and add the following below the existing

AppSettings configuration section in the file (before the final closing bracket):

```
"extensions": {
   "Keyfactor.Orchestrators.ScriptDrivers.IScriptDriver": {
      "RegisteredScriptDriver": {
         "assemblypath": "Keyfactor.Orchestrators.BashDriver.dll",
         "TypeFullName": "Keyfactor.Orchestrators.ScriptDrivers.BashDriver"
      }
   }
}
```

After the Bash script driver is registered, you may enter a path to the Bash script in the orchestrator manifest.json file *PreScript* section. The script may be placed anywhere on the orchestrator machine. The orchestrator will need read permissions to the script.

Tip: If your script fails, this will cause the entire job to fail. You can use this to your advantage if you'd like to fail the job under certain conditions by doing a *Write-Error* on Windows or *exit <error code>* on Linux.

For more information about calling scripts from the orchestrator, contact your Keyfactor representative.

- Each section may optionally have a *PostScript* reference, which points to a script file on the orchestrator machine that will run after the main job for the section executes. See the notes for script use under *PreScript*.
- User-defined certificate store jobs support up to four job types—Inventory, Management, Discovery, and Reenrollment. Each one of these job types should have a separate section in the file.

```
{
   "extensions": {
      "Keyfactor.Orchestrators.Extensions.IOrchestratorJobExtension": {
         "CertStores.MyStore.Inventory": {
            "assemblypath": "Keyfactor.Orchestrators.MyStore.dll",
            "TypeFullName": "Keyfactor.Orchestrators.MyStore.MyStoreInventoryJobExtension"
         },
         "CertStores.MyStore.Management": {
            "assemblypath": "Keyfactor.Orchestrators.MyStore.dll",
            "TypeFullName": "Keyfactor.Orches-
trators.MyStore.MyStoreManagementJobExtension",
            "PreScript": "C:\\Program Files\\Keyfactor\\Keyfactor
Orchestrator\\extensions\\MyStoreManagementPreScript.ps1",
            "PostScript": "C:\\Program Files\\Keyfactor\\Keyfactor Orches-
trator\\extensions\\MyStoreManagementPostScript.ps1"
```

```
        },
        "CertStores.MyStore.Discovery": {
           "assemblypath": "Keyfactor.Orchestrators.MyStore.dll",
           "TypeFullName": "Keyfactor.Orchestrators.MyStore.MyStoreDiscoveryJobExtension"
        }
     }
  }
}
```

6. Restart the Universal Orchestrator service (see Start the Universal Orchestrator Service on page 2401).

7. In the Keyfactor Command Management Portal, re-approve the orchestrator. The orchestrator will update to a status of new (if it had been approved previously) upon receiving updated capabilities. See Orchestrator Management on page 454 in the *Keyfactor Command Reference Guide* for information on approving orchestrators.

8. In the Keyfactor Command Management Portal or using the Keyfactor API, add a certificate store type or custom job type for your custom-built extension, if applicable. See Adding or Editing a Certificate Store Type on page 604 in the *Keyfactor Command Reference Guide* or POST Custom Job Types on page 1283 in the *Keyfactor Web APIs Reference Guide*.

Contact your Keyfactor representative for more information about custom-built solutions or to obtain access to the NuGet packages required for development of Universal Orchestrator extensions.

5.2.4.4 Configuring Script-Based Certificate Store Jobs

The Keyfactor Universal Orchestrator supports the option to implement custom-built certificate store jobs using one or more scripts (PowerShell or Bash) rather than a full extension (see Installing Custom-Built Extensions on page 2392). To implement custom-built certificate store jobs in this way, you need to create your scripts that will execute the certificate store actions (e.g. inventory, add certificates, remove certificates) and a manifest.json file to reference the jobs and install them on the orchestrator. Optionally, each certificate store action script can call a prescript and/or a postscript to perform actions before or after the main action.

Note: The scripting method of running custom-built certificate store jobs cannot be used to run other types of custom jobs. These are supported only with the use of a custom extension (see Installing Custom-Built Extensions on page 2392). However, both certificate store jobs and custom jobs support the use of prescripts and postscripts (see Orchestrator Job Overview on page 2356).

To configure a set of custom-built certificate store scripts:

1. On the Universal Orchestrator server, locate the scripts directory within the install directory. By default, this is:

   Windows: C:\Program Files\Keyfactor\Keyfactor Orchestrator\Scripts
   Linux: /opt/keyfactor/orchestrator/Scripts

2. Under the scripts directory, create a new directory with an appropriate name for your custom-built certificate store job set (e.g. MyStore). This name matches the name of the job referenced in the manifest.json file.

3. Place the scripts created for your custom-built certificate store job set in the new directory. Supported script file names are:

    - Add (e.g. Add.ps1 or Add.sh)
      A management job to add a certificate to the certificate store.
    - Create (e.g. Create.ps1 or Create.sh)
      A management job to create the certificate store if it does not already exist.
    - Discovery (e.g. Discovery.ps1 or Discovery.sh)
      A discovery job.
    - Inventory (e.g. Inventory.ps1 or Inventory.sh)
      An inventory job.
    - Reenrollment (e.g. Reenrollment.ps1 or Reenrollment.sh)
      A reenrollment job.
    - Remove (e.g. Remove.ps1 or Remove.sh)
      A management job to remove a certificate from the certificate store.

4. In order to use a Bash script with orchestrators installed on Linux, you must first register the Bash script driver in the appsettings.json file. This file is found in the configuration directory. Edit the file and add the following below the existing AppSettings configuration section in the file (before the final closing bracket):

    ```
    "extensions": {
       "Keyfactor.Orchestrators.ScriptDrivers.IScriptDriver": {
          "RegisteredScriptDriver": {
             "assemblypath": "Keyfactor.Orchestrators.BashDriver.dll",
             "TypeFullName": "Keyfactor.Orchestrators.ScriptDrivers.BashDriver"
          }
       }
    }
    ```

5. On the Universal Orchestrator server, locate the JobExtensionDrivers directory within the extensions directory under the install directory. By default, this is:

    Windows: C:\Program Files\Keyfactor\Keyfactor Orchestrator\extensions\JobExtensionDrivers
    Linux: /opt/keyfactor/orchestrator/extensions/JobExtensionDrivers

6. In the JobExtensionDrivers directory, create a file called manifest.json or open the existing one. There should be only one manifest.json file no matter how many script directories you create.

7. Using a text editor, edit the manifest.json file and configure it appropriately for your custom-built certificate store job set. Some things to keep in mind are:

- The opening and closing lines of the file must match those shown in red here:

```
{
   "extensions": {
      "Keyfactor.Orchestrators.Extensions.IOrchestratorJobExtension":
{
         "CertStores.MyStore.Inventory": {
            "assemblypath": "Keyfactor.Orchestrators.JobExtensionDrivers.dll",
            "TypeFullName": "Keyfactor.Orches-
trators.JobExtensionDrivers.InventoryJobExtensionDriver"
         }
      }
   }
}
```

- Each customized section of the file starts with a certificate store reference (e.g. CertStores.MyStore.Inventory). Certificate stores jobs (beginning *CertStores*) correspond to certificate store types created with the Keyfactor API *POST /CertifiateStoreType* method (see POST Certificate Store Types on page 1247 in the *Keyfactor Web APIs Reference Guide*) or in the Keyfactor Command Management Portal (see Adding or Editing a Certificate Store Type on page 604 in the *Keyfactor Command Reference Guide*). For example, a custom certificate store type with a *Capability* of *MyStore* configured to do inventory, management and discovery, would have three separate sections in the file as *CertStores.MyStore.Inventory*, *CertStores.MyStore.Management*, and *CertStores.MyStore.Discovery*. The capability reference (e.g. MyStore) must also match the name you give to the directory where you place your scripts. An inventory section is required.
- The *assemblypath* referenced in each section points to the DLL in the extensions directory of the Job Extensions Driver extension. This built-in extension is used to run custom-built certificate store jobs as scripts. This value will be the same for all entries in the file.
- The *TypeFullName* referenced in each section corresponds to the name of the type that resides inside of the DLL listed for the assembly path—the Job Extensions Driver extension in this case. This value will be the same for all entries in the file.
- Each section may optionally have a *PreScript* reference, which points to an additional script file on the orchestrator machine that will run before the main job for the section executes.

  Tip: If either your PreScript or PostScript fails, this will cause the entire job to fail. You can use this to your advantage if you'd like to fail the job under certain conditions by doing a *Write-Error* on Windows or *exit <error code>* on Linux.

- Each section may optionally have a *PostScript* reference, which points to an additional script file on the orchestrator machine that will run after the main job for the section executes.
- Custom-built certificate store jobs support up to four job types—Inventory, Management, Discovery, and Reenrollment. Each one of these job types should have a separate section in the file.

```
{
   "extensions": {
      "Keyfactor.Orchestrators.Extensions.IOrchestratorJobExtension": {
         "CertStores.MyStore.Inventory": {
            "assemblypath": "Keyfactor.Orchestrators.JobExtensionDrivers.dll",
            "TypeFullName": "Keyfactor.Orches-
trators.JobExtensionDrivers.InventoryJobExtensionDriver"
         },
         "CertStores.MyStore.Management": {
            "assemblypath": "Keyfactor.Orchestrators.JobExtensionDrivers.dll",
            "TypeFullName": "Keyfactor.Orches-
trators.JobExtensionDrivers.InventoryJobExtensionDriver"
            "PreScript": "C:\\Program Files\\Keyfactor\\Keyfactor
Orchestrator\\scripts\\MyStore\\MyStoreManagementPreScript.ps1",
            "PostScript": "C:\\Program Files\\Keyfactor\\Keyfactor Orches-
trator\\scripts\\MyStore\\MyStoreManagementPostScript.ps1"
         },
         "CertStores.MyStore.Discovery": {
            "assemblypath": "Keyfactor.Orchestrators.JobExtensionDrivers.dll",
            "TypeFullName": "Keyfactor.Orches-
trators.JobExtensionDrivers.InventoryJobExtensionDriver"
         },
         "CertStores.MyStore.Reenrollment": {
            "assemblypath": "Keyfactor.Orchestrators.JobExtensionDrivers.dll",
            "TypeFullName": "Keyfactor.Orches-
trators.JobExtensionDrivers.InventoryJobExtensionDriver"
         }
      }
   }
}
```

8. Restart the Universal Orchestrator service (see Start the Universal Orchestrator Service on page 2401).

9. In the Keyfactor Command Management Portal, re-approve the orchestrator. The orchestrator will update to a status of new (if it had been approved previously) upon receiving updated capabilities. See Orchestrator Management on page 454 in the *Keyfactor Command Reference Guide* for information on approving orchestrators.

Contact your Keyfactor representative for more information about custom solutions or for assistance creating custom scripts.

5.2.4.5 Configure Logging for the Universal Orchestrator

Keyfactor Universal Orchestrator provides extensive logging for visibility and troubleshooting. For more information about troubleshooting, see Troubleshooting on page 2444.

By default, the Keyfactor Universal Orchestrator places its log files in the logs directory under the installed directory, generates logs at the "Info" logging level and stores logs for two days before deleting them. If you wish to change these defaults, follow the directions below for your installation type.

Windows Installations

1. On the Windows server where you wish to adjust logging, open a text editor (e.g. Notepad) using the "Run as administrator" option.

2. In the text editor, browse to open the Nlog.config file for the Universal Orchestrator. The file is located in the configuration directory within the install directory, which is the following directory by default:

   C:\Program Files\Keyfactor\Keyfactor Orchestrator\configuration

3. Your Nlog.config file may have a slightly different layout than shown here, but it will contain the five fields highlighted in Figure 533: Universal Orchestrator on Windows NLog.config File. The fields you may wish to edit are:

   - variable name="logDirectory" value="logs/"

     The path to the log file location.

     > **Important:** If you choose to change the path for storage of the log files, you will need to create the new directory (e.g. D:\KeyfactorLogs) and grant the Universal Orchestrator service account under which the Keyfactor Orchestrator Service is running full control permissions on this directory.

   - fileName="${logDirectory}/Log.txt"

     The path and file name of the active orchestrator log file, referencing the logDirectory variable.

   - archiveFileName="${logDirectory}/Log_Archive_{#}.txt"

     The path and file name of previous days' orchestrator log files, referencing the logDirectory variable. The orchestrator rotates log files daily and names the previous files using this naming convention.

   - maxArchiveFiles="2"

     The number of archive files to retain before deletion.

   - name="*" minlevel="Info" writeTo="logfile"

     The level of log detail that should be generated and output to the log file. The default "Info" level logs error and some informational data but at a minimal level to avoid generating large log files. For troubleshooting, it may be desirable to set the logging level to "Debug" or "Trace". Available log levels (in order of increasing verbosity) are:

     - OFF—No logging
     - FATAL—Log severe errors that cause early termination
     - ERROR—Log severe errors and other runtime errors or unexpected conditions that may not cause early termination
     - WARN—Log errors and use of deprecated APIs, poor use of APIs, "almost" errors, and other runtime situations that are undesirable or unexpected but not necessarily "wrong"

- INFO—Log all of the above plus runtime events (startup/shutdown)
- DEBUG—Log all of the above plus detailed information on the flow through the system
- TRACE—Maximum log information—this option can generate VERY large log files

```
<variable name="logDirectory" value="logs/" />
<targets>
  <target name="buffered_wrapper" xsi:type="BufferingWrapper" slidingTimeout="true" bufferSize="500" flushTimeout="500">
    <target xsi:type="File" name="logfile" fileName="${logDirectory}/Log.txt" layout="${longdate} ${logger} [${level}] - ${message}"
            archiveFileName="${logDirectory}/Log_Archive_{#}.txt" archiveEvery="Day" archiveNumbering="Rolling" maxArchiveFiles="2" archiveAboveSize="2147483648" />
  </target>
  <target xsi:type="OutputDebugString" name="String" layout="${longdate} ${logger}::${message}" />
  <target xsi:type="Debugger" name="debugger" layout="${longdate} ${logger}::${message}" />
  <target xsi:type="Console" name="console" layout="${logger} ${message}" />
  <target xsi:type="EventLog" name="eventLog" source="Keyfactor Orchestrator"
          eventId="${event-properties:item=eventID}" category="${event-properties:item=categoryID}" layout="${event-properties:item=message}" />
</targets>
<rules>
  <logger name="*-EVENT" minlevel="Info" writeTo="eventLog" final="true" />
  <logger name="*" minlevel="Info" writeTo="console" />
  <logger name="*" minlevel="Info" writeTo="logfile" >
    <filters>
      <when condition="contains('${logger}', 'Quartz') and level &lt; LogLevel.Warn" action="IgnoreFinal" />
      <when condition="starts-with('${logger}', 'Microsoft.Hosting.Lifetime') and level &gt;= LogLevel.Info" action="LogFinal" />
      <when condition="starts-with('${logger}', 'Microsoft.Azure.SignalR') and level &gt;= LogLevel.Debug" action="LogFinal" />
      <when condition="starts-with('${logger}', 'Microsoft.AspNetCore')" action="Ignore" />
      <when condition="starts-with('${logger}', 'Microsoft') and level &lt; LogLevel.Warn" action="Ignore" />
    </filters>
  </logger>
</rules>
```

Figure 533: Universal Orchestrator on Windows NLog.config File

Linux Installations

1. On the orchestrator machine where you wish to adjust logging, open a command shell and change to the directory in which the orchestrator is installed. By default this is /opt/keyfactor/orchestrator.

2. In the command shell in the directory in which the orchestrator is installed, change to the configuration directory.

3. Using a text editor, open the nlog.config file in the configuration directory. Your nlog.config file may have a slightly different layout than shown here, but it will contain the five fields highlighted in the below figure. The fields you may wish to edit are:

    - variable name="logDirectory" value="logs/"

      The path to the log file location.

      Important: If you choose to change the path for storage of the log files, you will need to create the new directory (e.g. /opt/kyflogs) and grant the Universal Orchestrator service account under which the keyfactororchestrator-default service is running full control permissions on this directory.

    - fileName="${logDirectory}/Log.txt"

      The path and file name of the active orchestrator log file, referencing the logDirectory variable.

    - archiveFileName="${logDirectory}/Log_Archive_{#}.txt"

      The path and file name of previous days' orchestrator log files, referencing the logDirectory variable. The orchestrator rotates log files daily and names the previous files using this naming convention.

    - maxArchiveFiles="2"

The number of archive files to retain before deletion.

- name="*" minlevel="Info" writeTo="logfile"

  The level of log detail that should be generated and output to the log file. The default "Info" level logs error and some informational data but at a minimal level to avoid generating large log files. For troubleshooting, it may be desirable to set the logging level to "Debug" or "Trace". Available log levels (in order of increasing verbosity) are:

  - OFF—No logging
  - FATAL—Log severe errors that cause early termination
  - ERROR—Log severe errors and other runtime errors or unexpected conditions that may not cause early termination
  - WARN—Log errors and use of deprecated APIs, poor use of APIs, "almost" errors, and other runtime situations that are undesirable or unexpected but not necessarily "wrong"
  - INFO—Log all of the above plus runtime events (startup/shutdown)
  - DEBUG—Log all of the above plus detailed information on the flow through the system
  - TRACE—Maximum log information—this option can generate VERY large log files

```

```

Figure 534: Universal Orchestrator on Linux NLog.config File

5.2.4.6 Start the Universal Orchestrator Service

The Keyfactor Universal Orchestrator service runs on the orchestrator server and controls orchestrator communications with the Keyfactor Command server. During the configuration process you set the service account under which the orchestrator service will run. The service should start automatically at the conclusion of the installation. To check to see if it's running and start it if necessary, follow the directions below for your installation type.

Windows Installations

The service on Windows is added with a display name of Keyfactor Orchestrator Service (Default) by default.

1. On the Universal Orchestrator server, open the Services MMC.
2. In the Services MMC confirm that the Keyfactor Orchestrator Service is set to a Startup Type of Automatic (if desired). If the service is not running, click the green arrow to start it.

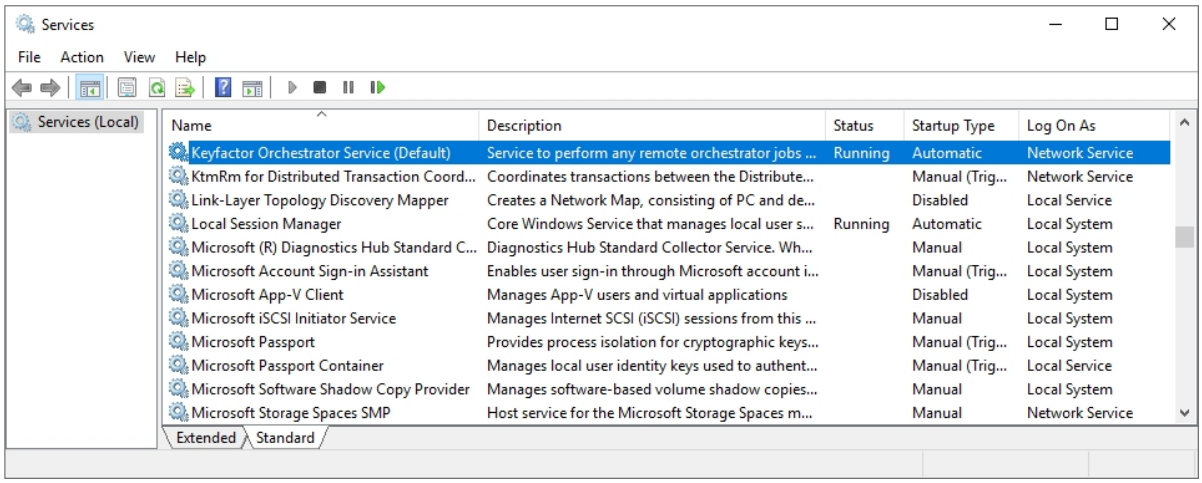

Figure 535: Universal Orchestrator Service

Note: Your service will have a name other than *(Default)* following *Keyfactor Orchestrator Service* if you opted to use the *ServiceSuffix* installation parameter.

Linux Installations

The service on Linux is added as keyfactor-orchestrator-default by default, so when referencing it in startup commands, it should be referenced by this name, including case. For example:

```
systemctl start [stop] [restart] [status] keyfactor-orchestrator-default.service
```

Note: Your service will have a name other than *default* following *keyfactor-orchestrator-* if you opted to use the *service-suffix* installation parameter.

5.2.4.7 Change Service Account Passwords

The process for changing the passwords for the service accounts used by the Keyfactor Universal Orchestrator varies for the two different service accounts (see Create Service Accounts for the Universal Orchestrator on page 2362) and based on the type of authentication used for the service account used to connect to Keyfactor Command.

Universal Orchestrator Service Account

The password for the service account that's used to run the Universal Orchestrator service on the orchestrator server can be changed through standard operating system methods.

On a Linux server, this would be, for example, the command line *passwd* command executed for the service account running the orchestrator service (by default *keyfactor-orchestrator*). So, this command on a Linux server might be:

```
sudo passwd keyfactor-orchestrator
```

On a Windows server, if you've opted to run the Universal Orchestrator service as a custom service account rather than *Network Service*, the password would need to be changed in Active Directory and in the Services MMC.

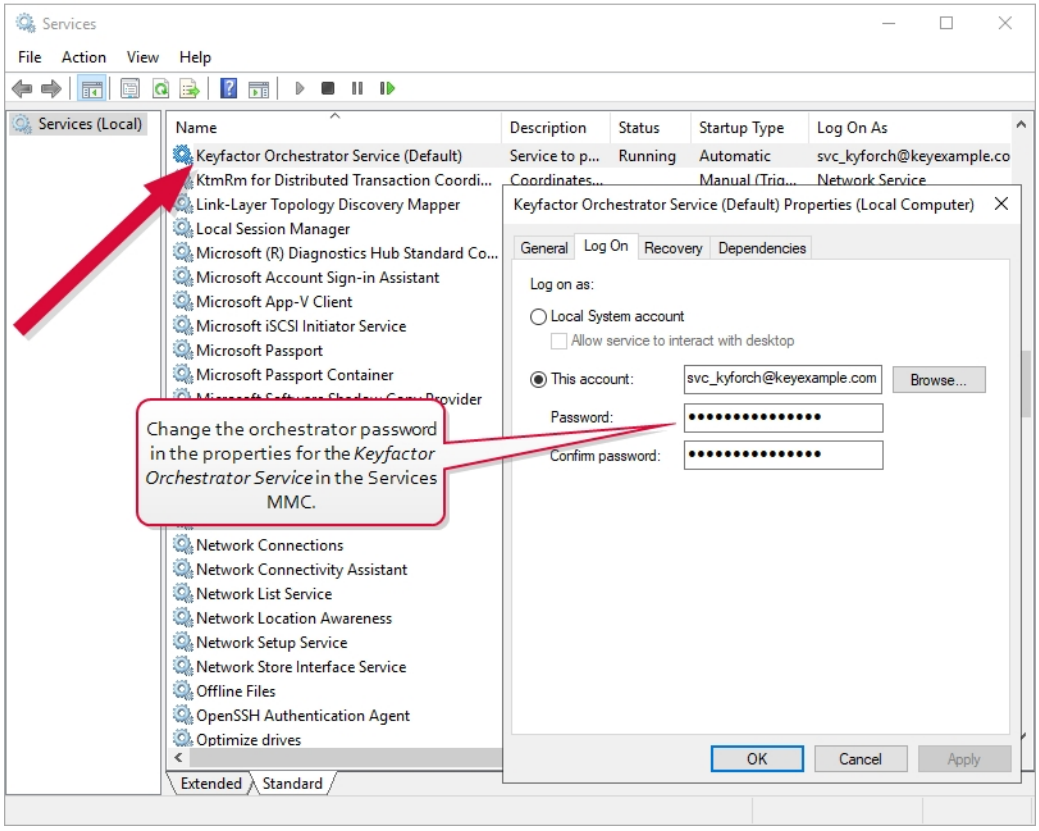

Figure 536: Change Service Account Password in Services MMC

Keyfactor Command Connect Service Account with Basic Authentication

For both Windows and Linux servers, the password change for the service account that's used to make the connection to Keyfactor Command follows this process:

1. Change the password for the service account in Active Directory.

2. On the Windows or Linux server, open a command window. For Windows, this should be a PowerShell window open using the "Run as Administrator" option. Change to the directory in which the orchestrator is installed and locate the change_secrets script. By default, this is:

   ```
   Windows: C:\Program Files\Keyfactor\Keyfactor Orchestrator\change_secrets.ps1
   Linux: /opt/keyfactor/orchestrator/change_secrets.sh
   ```

3. For Linux only, use the chmod command to make the change_secrets.sh script file executable. The file ships in a non-executable state to avoid accidental execution. For example:

   ```
   sudo chmod +x change_secrets.sh
   ```

4. For Windows only, in the PowerShell window, run the following command to populate a variable with the password for the service account:

   ```
   $credKeyfactor = Get-Credential
   ```

   Enter the appropriate username and password when prompted (the service account that the orchestrator uses to connect to Keyfactor Command). Usernames should be given in DOMAIN\username format.

   Or, to avoid being prompted for credentials:

   ```
   $keyfactorUser = "DOMAIN\mykeyfactorconnectusername"
   $keyfactorPassword = "MySecurePassword"
   $secKeyfactorPassword = ConvertTo-SecureString $keyfactorPassword -AsPlainText -Force
   $credKeyfactor = New-Object System.Management.Automation.PSCredential ($keyfactorUser,
   $secKeyfactorPassword)
   ```

5. Run the password change script on the Universal Orchestrator server using the following parameters:

   ### -WebCredential (Windows)

   This is the credential object of the service account that the orchestrator uses to communicate with Keyfactor Command that you created as per Create Service Accounts for the Universal Orchestrator on page 2362. It is provided as a PSCredential object.

   For password change operations, this parameter is **required**.

   ### --username (Linux)

   The service account that the orchestrator uses to communicate with Keyfactor Command created as per Create Service Accounts for the Universal Orchestrator on page 2362. It may be entered either as username@domain (e.g. svc_kyforch@keyexample.com) or DOMAIN\\username (e.g. KEYEXAMPLE\\svc_kyforch).

   For password change operations, this parameter is **required**.

   ### --password (Linux)

   The password for the service account that the orchestrator uses to communicate with Keyfactor Command specified with the *username* parameter.

   Warning: The password for the service account the orchestrator uses to communicate with Keyfactor Command is stored in clear text in the orchestratorsecrets.json file in the configuration directory under the installation directory for the orchestrator. By default, this file is granted read/write permissions for the orchestrator service account running the service on the Linux

machine (*keyfactor-orchestrator* by default) and no permissions for any other users. Access to this file should be strictly controlled.

This parameter is **required** if the *username* parameter is specified.

Tip: If you prefer to avoid providing the password at the command line (and storing it in command history), use an input file instead as follows:

a. Create a file that contains just your password. For example:
```
vi my_password_file
```

b. When using the password parameter, reference the file. For example:
```
--password $(cat my_password_file)
```

c. Delete the password file after the install is complete. For example:
```
rm my_password_file
```

-SecretsPath (Windows) or --secrets-path (Linux)

The full path and file name of the or the orchestratorsecrets.json file that stores the secret information. This file is found in the configuration directory under the installation directory for the Universal Orchestrator, which is by default:

```
Windows: C:\Program Files\Keyfactor\Keyfactor
Orchestrator\configuration\orchestratorsecrets.json
Linux: /opt/keyfactor/orchestrator/configuration/orchestratorsecrets.json
```

The location and file name for this file cannot be changed from the default. The parameter is provided to allow for installations in non-standard locations or multiple locations on the same server.

This parameter is **required**.

Windows example using basic authentication:

```
$keyfactorUser = "KEYXAMPLE\svc_kyforch"
$keyfactorPassword = "MySecurePassword123!"
$secKeyfactorPassword = ConvertTo-SecureString $keyfactorPassword -AsPlainText -Force
$credKeyfactor = New-Object System.Management.Automation.PSCredential ($keyfactorUser, $secKey-
factorPassword)

.\change_secrets.ps1 -WebCredential $credKeyfactor -SecretsPath "C:\Program Files\Keyfactor\Keyfactor
Orchestrator\configuration\orchestratorsecrets.json"

Saved secrets to 'C:\Program Files\Keyfactor\Keyfactor Orches-
trator\configuration\orchestratorsecrets.json'
Restarting service KeyfactorOrchestrator-Default
```

Linux example using basic authentication:

```
vi password_file_new

sudo ./change_secrets.sh --username svc_kyforch@keyexample.com --password $(cat password_file_new) --
secrets-path /opt/keyfactor/orchestrator/configuration/orchestratorsecrets.json

Saving secrets to '/opt/keyfactor/orchestrator/configuration/orchestratorsecrets.json'
Restarting service keyfactor-orchestrator-default
```

5.2.4.8 Register a Client Certificate Renewal Extension

The Keyfactor Universal Orchestrator supports automated renewal of the certificate used for client certificate authentication. It does this using a custom extension point interface on the orchestrator that can be implemented by the end user. When the client certificate used for authentication by the orchestrator is approaching expiration (within 180 days of expiration by default), the extension generates a CSR with a private key and submits the CSR to Keyfactor Command for enrollment. When Keyfactor Command returns the certificate to the orchestrator, it is paired with the private key and installed for use as the client certificate for authentication. The extension both supplies the information for the CSR and holds a dictionary of client parameters (see Build a Client Certificate Renewal Extension on page 2411).

To register a client authentication certificate renewal extension:

1. Create the extension DLL (see Build a Client Certificate Renewal Extension on page 2411).
2. On the Universal Orchestrator server, locate the extensions folder under the install directory for the orchestrator. By default, this is:

   ```
   Windows: C:\Program Files\Keyfactor\Keyfactor Orchestrator\extensions
   Linux: /opt/keyfactor/orchestrator/extensions
   ```

3. Under the extensions directory, create a new directory for your extension (e.g. CertRotation).
4. Place your DLL in the new CertRotation directory.
5. Create a manifest.json file in the CertRotation directory with the following contents:

   ```
   {
      "extensions": {
         "Keyfactor.Orchestrators.Extensions.IOrchestratorRegistrationUpdater": {
            "RegisteredRegistrationUpdater": {
               "assemblypath": "RegistrationUpdater.dll",
               "TypeFullName": "Custom.Registration.Updaters.CustomRegistrationUpdater",
               "config": {
                  "DnsSan": "orchestrator_name.keyexample.com",
                  "Subject": "CN=Client Certificate Authentication",
   ```

```
            "DataCenter": "WestCoast",
            "ForceRenewal": "False"
        }
    }
  }
 }
}
```

Only the values shown in red above should be modified from what is shown in this example:

- The *assemblypath* is the name of your DLL.
- The example Custom.Registration.Updaters portion of the *TypeFullName* must match the *namespace* in your code. The example CustomRegistrationUpdater portion of the *TypeFullName* must match the *class* in your code.
- The config section is only needed if you wish to pass configuration values such as a standard DNS SAN or certificate subject into the extension. Those shown here are examples that match the sample code (see Build a Client Certificate Renewal Extension on page 2411).

The certificate renewal process occurs as follows:

1. When each registration or session renewal of the orchestrator service occurs, the orchestrator, in conjunction with underlying Keyfactor Command functionality, checks the expiration date of the client authentication certificate and compares that with the defined client certificate warning period (180 days) and expiry period (30 days) in Keyfactor Command to determine whether a new certificate is needed.

   Note: If the certificate is in the warning period, operations will continue while a new certificate is requested. If the certificate is in the expiry period or already expired, the orchestrator will not be allowed to register a new session when the existing session expires or the orchestrator service is restarted.
   Orchestrator log messages indicating that a certificate is in the warning period look similar to the following:

   ```
   2021-09-17 12:45:59.7927 Keyfactor.Orchestrators.JobEngine.SessionClient [Warn] - Remote
   CMS call 'https://keyfactor.keyexample.com/KeyfactorAgents/Session/Register' returned:
   Agent certificate is approaching expiration and should be renewed. (A0100007)
   ```

   Orchestrator log messages indicating that a certificate is in the expiry period look similar to the following:

   ```
   2021-09-09 17:27:37.5367 Keyfactor.Orchestrators.JobEngine.SessionClient [Error] - Remote
   CMS call 'https://keyfactor.keyexample.com/KeyfactorAgents/Session/Register' returned:
   Agent certificate is approaching expiration and must be renewed. (A0100008)
   ```

```
2021-09-09 17:27:37.5642 Keyfactor.Orchestrators.JobEngine.SessionJobExecutor [Error] -
Error in SessionManager: Unable to register session.
   at Keyfactor.Orchestrators.JobEngine.SessionClient.RegisterAsync(IEnumerable`1 capab-
ilities, CancellationToken cancellationToken)
   at Keyfactor.Orchestrators.JobEngine.SessionJobExecutor.Execute(IJobExecutionContext
context)

Error: A0100008
Agent certificate is approaching expiration and must be renewed.
   at Keyfactor.Orchestrators.JobEngine.SessionClient.RegisterAsync(IEnumerable`1 capab-
ilities, CancellationToken cancellationToken)
```

Tip: The length of the warning period and expiry period are defined in Keyfactor Command and are not user-configurable values. Contact support@keyfactor.com if you need to modify these values.

Tip: The orchestrator can be forced into the warning or expiry state before it reaches these based on certificate lifetime using the *POST /Agents/SetAuthCertificateReenrollment* method in the Keyfactor API or the *Request Renewal* button on the Orchestrator Management page of the Keyfactor Command Management Portal. A status of *Request* (1) is the equivalent of the warning period and a status of *Require* (2) is the equivalent of the expiry period.

2. When either the warning period or expiry period is identified, the Keyfactor Universal Orchestrator will pass a value of *true* to the GetCSRInfo method (*newOrchestratorCertRequestedByPlatform* in the sample extension—see Build a Client Certificate Renewal Extension on page 2411). The extension generates a private key and a CSR using CSR information (e.g. subject, key size) provided or generated by the extension (depending on the extension design), returns the CSR to the orchestrator, which submits it to Keyfactor Command for certificate enrollment.

   If the certificate is within the warning period but not within the expiry period, orchestrator activity will be allowed to continue as usual. If the certificate is within the expiry period, a new session will not be granted when the orchestrator requests a new session and orchestrator activity will not be allowed to continue until the orchestrator acquires a new certificate. If the certificate has expired, the certificate rotation cannot take place since the orchestrator cannot authenticate to Keyfactor Command to complete the rotation.

   Tip: If a certificate has expired or some other certificate problem is causing the orchestrator not to be able to acquire a session, the orchestrator can be reset using either the Reset button on the Orchestrator Management page in the Keyfactor Command Management Portal or the *POST /Agents/{id}/Reset* method in the Keyfactor API. This removes the certificate history and allows the orchestrator to register for a session with the certificate currently configured in the appsettings.json file under the configuration directory. You will need to re-approve the orchestrator if you reset it.

3. In Keyfactor Command, a certificate is issued based on:

- The OrchestratorConstants.CertificateAttributes.CERTIFICATE_AUTHORITY and OrchestratorConstants.CertificateAttributes.CERTIFICATE_TEMPLATE values defined in the custom registration handler enroll function.
- If no values are supplied in the custom registration handler enroll function, the certificate authority and template defined by the *Certificate Authority For Submitted CSRs* and *Template For Submitted CSRs* application settings in the Keyfactor Command Management Portal.

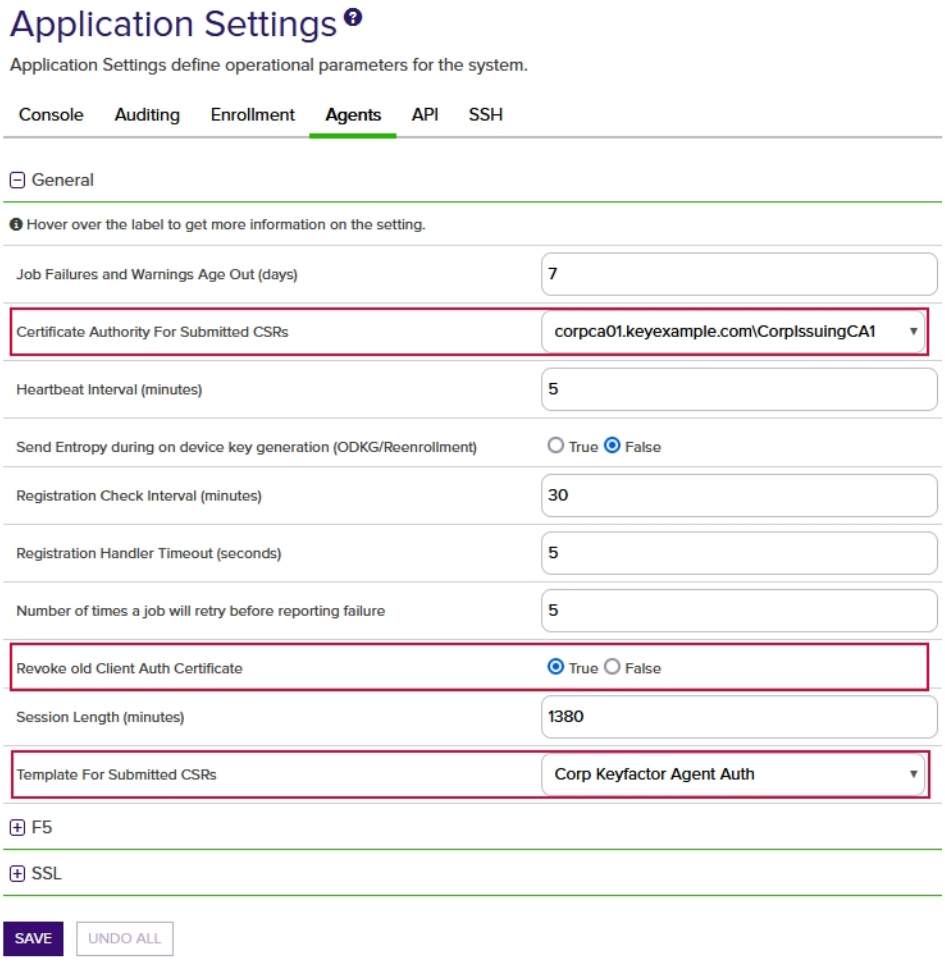

Figure 537: Application Settings for Client Certificate Renewal

4. Once the certificate is issued, it is returned to the orchestrator and married with the private key. If certificate authentication is configured using a certificate stored in the local computer or Universal Orchestrator service account user's personal store (Windows only), the orchestrator updates the *appsettings.json* file with the thumbprint of the new certificate. The thumbprint is stored in the *AuthCertThumbprint* value in the *appsettings.json* file (see Change Service Account Passwords on page 2402). If certificate authentication is configured using a PKCS12 file stored in the file system, a PKCS12 file is generated and replaces the original PKCS12 file. The randomly generated password for the PKCS12 file is updated in the *orchestratorsecrets.json* file.

Note: If certificate authentication is configured using a certificate stored in the local computer personal store on Windows, when the new certificate is generated, it will be placed in the service account user's personal store, not the local computer personal store. This is true if the service is running as a domain account and if the service is running as the default *Network Service*.

5. With the orchestrator's next session registration or heartbeat, it will begin using the new certificate.

   Tip: If you manually configured the orchestrator to renew the certificate using the *POST /Agents/SetAuthCertificateReenrollment* method in the Keyfactor API or the *Request Renewal* button on the Orchestrator Management page, that flag will be cleared when the orchestrator successfully registers for a session or completes a heartbeat using the new certificate.
   Once a new session is established with the new certificate, the stored legacy thumbprint for the replaced certificate will be removed from the database. This occurs whether or not you opt to automatically revoke the old certificate and occurs before the certificate revocation takes place. The legacy thumbprint is not cleared on a heartbeat with the new certificate.

6. If you've opted to enable the *Revoke old Client Auth Certificate* application setting (see Figure 537: Application Settings for Client Certificate Renewal) in Keyfactor Command, the previous certificate for the orchestrator will be revoked automatically by Keyfactor Command once the orchestrator has made a successful registered for a new session with the new certificate.

   Important: The Universal Orchestrator service account under which the orchestrator is operating must have permissions to enroll for certificates from the CA and have at least the *Enroll CSR* role permission for *Certificate Enrollment* and the *Read* role permission for *Certificates* in Keyfactor Command. If you've opted to enable automated revocation of the old certificate, the service account must also have permissions to revoke certificates on the CA and have at least the *Revoke* role permission for *Certificates* in Keyfactor Command.

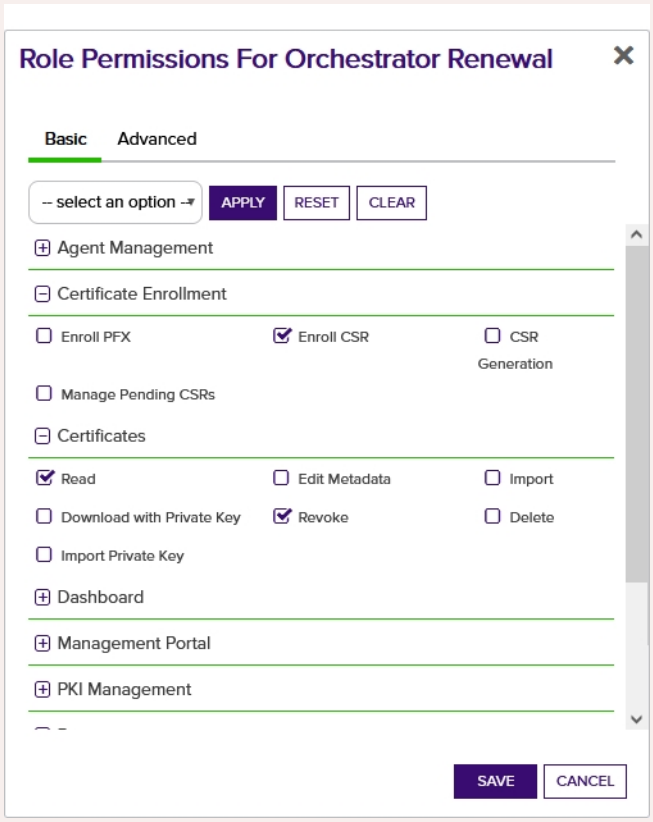

Figure 538: Keyfactor Command Permissions Required for Automatic Renewal and Revocation of Client Authentication Certificates

Build a Client Certificate Renewal Extension

The functionality to renew the certificate used by the Keyfactor Universal Orchestrator for authentication is available via an extension point interface provided by Keyfactor. To implement a custom extension, you will need to obtain the *Keyfactor.Orchestrators.IOrchestratorRegistrationUpdater* nuget package from Keyfactor. Contact your Client Success Manager or support@keyfactor.com for assistance with that.

To build a client certificate renewal extension:

1. Create a project for the extension in your favorite integrated development environment (e.g. Visual Studio).
2. Import the *Keyfactor.Orchestrators.IOrchestratorRegistrationUpdater* nuget package into the project.
3. Consult the sample code to help you design your extension. A sample extension for the client authentication registration updater interface is provided on the Keyfactor GitHub:

   ```
   https://keyfactor.github.io/
   ```

4. Build an assembly file (DLL file) containing the extension.

5. Follow the instructions for registering the extension (see Register a Client Certificate Renewal Extension on page 2406).

5.3 Java Agent

The Keyfactor Java Agent allows organizations to run discovery jobs to locate Java keystores on Windows and Linux systems and PEM certificate stores on Linux systems, inventory the certificates found in them, and push new certificates out to them.

The system requirements for the Java Agent on Windows are:

- 64-bit versions of Windows 8.1, Windows 10, and Windows Server 2019
- 64-bit versions of Oracle Java or OpenJDK 8, 11 or 13
- The WiX Toolset (http://wixtoolset.org/) for users wishing to build an MSI

> **Note:** The path to the WiX executables needs to be added to the System PATH (e.g. C:\Program Files (x86)\WiX Toolset v3.11\bin) to support this.

The system requirements for the Java Agent on Linux are:

- Red Hat 6 or greater, CentOS 6 or greater, or Ubuntu 14 or greater
- 64-bit versions of Oracle Java or OpenJDK 8, 11 or 13
- JSVC on SysV style (init.d) systems

5.3.1 Preparing for the Java Agent

This section describes the steps that need to be taken prior to a Java Agent installation to install the prerequisites, create the required supporting components, and gather the necessary information to complete the Java Agent installation and configuration process.

5.3.1.1 Create Service Accounts for the Java Agent

The Java Agent makes use of up to two service accounts to allow it to communicate with the Keyfactor Command server. These two service accounts work together to transfer information from the Java Agent to the Keyfactor Command server. The two service accounts can be thought of as players on two sides of a fence, with the service account for the Java Agent lobbing information over the fence to the service account on the Keyfactor Command server side to catch and hand to the Keyfactor Command server:

- Java Agent Side
  On the Java Agent side of the fence, you may use either a local account or an Active Directory service account.

Windows

For domain-joined Windows machines, an Active Directory service account is typically used. For non-domain-joined Windows machines, you may use a local account created on the Windows machine as the service account instead of a domain account.

The service account under which the Keyfactor Java Agent service runs on Windows must be granted permissions to "Log on as a service" through local security policy. This step is generally done automatically as part of the installation scripts, but may need to be completed by hand in certain environments or on certain operating systems. The service account needs sufficient permissions to allow it to discover and inventory Java keystores and PEM certificate stores as applicable (read permissions on the appropriate files and directories) and update the stores if desired (write permissions on the files and directories in which the files are stored).

Important: During the installation process, you enter the Java agent service identity username and password interactively in a PowerShell window to configure the service account. PowerShell will not support the following characters in the service account password when used in this interface:

```
" $
```

If you need to support these characters in the password, you can re-enter the username and password in the Services MMC after receiving an error in the PowerShell interface.

Linux

For the purposes of this documentation it is assumed that Linux machines will be non-domain joined and will use a local account to run the Java Agent.

For Linux systems, Keyfactor recommends running the service as an account other than root.

- Keyfactor Command Server Side
  On the Keyfactor Command server side of the fence, an Active Directory service account in the primary Keyfactor Command server forest is used. This can be the same service account used for other Keyfactor Command server services. This service account appears in the Management Portal Orchestrator Management grid as the *Identity* for the Java Agent.

If the Java Agent is installed on a domain-joined machine in the same forest as the Keyfactor Command server, the same Active Directory service account may be used on both sides of the fence.

The service accounts need to be created prior to installation of the Java Agent software, and the person installing the Java Agent software needs to know the domain, username and password of each service account.

5.3.1.2 Create a Group for Java Agent Auto-Registration (Optional)

Keyfactor Command can use an Active Directory group to support auto-registration of Java Agents. Auto-registration is an optional feature that allows you to define the conditions under which a Java Agent can automatically be approved for operation with the Keyfactor Command server without administrator input, if desired. This is useful in environments hosting a large number of agents. There are six Java Agent auto-registration roles that share the same AD group:

Java Keystore Discovery

Auto-register the Java Agent to allow it to run discovery tasks to locate Java keystores.

Java Keystore Inventory Reporting

Auto-register the Java Agent to allow it to inventory certificates in Java keystores.

Java Keystore Management

Auto-register the Java Agent to allow it to manage (add/remove) certificates in Java keystores.

PEM Cert Store Management Jobs

Auto-register the Java Agent to allow it to manage (add/remove) certificates in PEM certificate stores.

PEM Server Configuration Directive Parser

Auto-register the Java Agent to allow it to run discovery tasks to locate PEM certificate stores.

PEM Server Inventory

Auto-register the Java Agent to allow it to inventory certificates in PEM certificate stores.

The same Active Directory group must be used for all roles. All auto-registration settings must be populated if any are to be used even if all features are not planned for use. For example, if you plan to use PEM but not Java keystore functionality, you still need to populate the Java keystore auto-registration settings to enable auto-registration for the Java Agent to function correctly.

Note: If all your agents will be connecting to Keyfactor Command as the same service account, you can directly add that user in the auto-registration configuration and skip using a group, if desired. Although you can choose to enable auto-registration without user validation, allowing any agent to register regardless of the user account under which the agent is running, user validation with either an Active Directory group or a specific Active Directory user is the more secure option.

5.3.1.3 Configure Certificate Root Trust for the Java Agent

Keyfactor recommends using HTTPS to secure the channel between each Java Agent and the Keyfactor Command server(s). This requires an SSL certificate configured in IIS on the Keyfactor Command server(s). This certificate can either be a publicly-rooted certificate (e.g. from Symantec, Entrust, etc.), or one issued from a private certificate authority (CA). If your Keyfactor Command server is using a publicly rooted certificate, the Java Agent machine may already trust the certificate root for this certificate. However, if you have opted to use an internally-generated certificate, your Java Agent server may not trust this certificate. In order to use HTTPS for communications between the Java Agent and the Keyfactor Command server with a certificate generated from a private CA, you will need to import the certificate chain for the certificate into a Java CA certificate store on the Java Agent server. This can be done automatically as part of the installation process. You will need to have the root certificate available as a PEM-encoded format file when you run the installation script.

5.3.1.4 Create Environment Variables for the Java Agent on Windows

The Keyfactor Java Agent determines the location of the current installed Java version on Windows by checking the Windows system environment variables Path and JAVA_HOME. Depending on how your version of Java was installed, these environment variables may or may not be set.

To check and set the environment variables for the Java Agent install:

1. Identify your Java base directory (e.g. C:\Program Files\Java\jdk-13.0.2). This directory typically contains the versioning and release files. Copy this path to a text file for easy access.

2. Identify the location of the Java virtual machine library (e.g. C:\Program Files\Java\jdk-13.0.2\bin\server-\jvm.dll), and copy the path to the text file created in the previous step.

3. Identity the location of the main Java executable (e.g. C:\Program Files\Java\jdk-13.0.2\bin\java.exe), and copy the path to the text file.

4. As a user with local administrator permissions, use the search function to search for *environment* and select the option to edit the *system environment variables* from the search results.

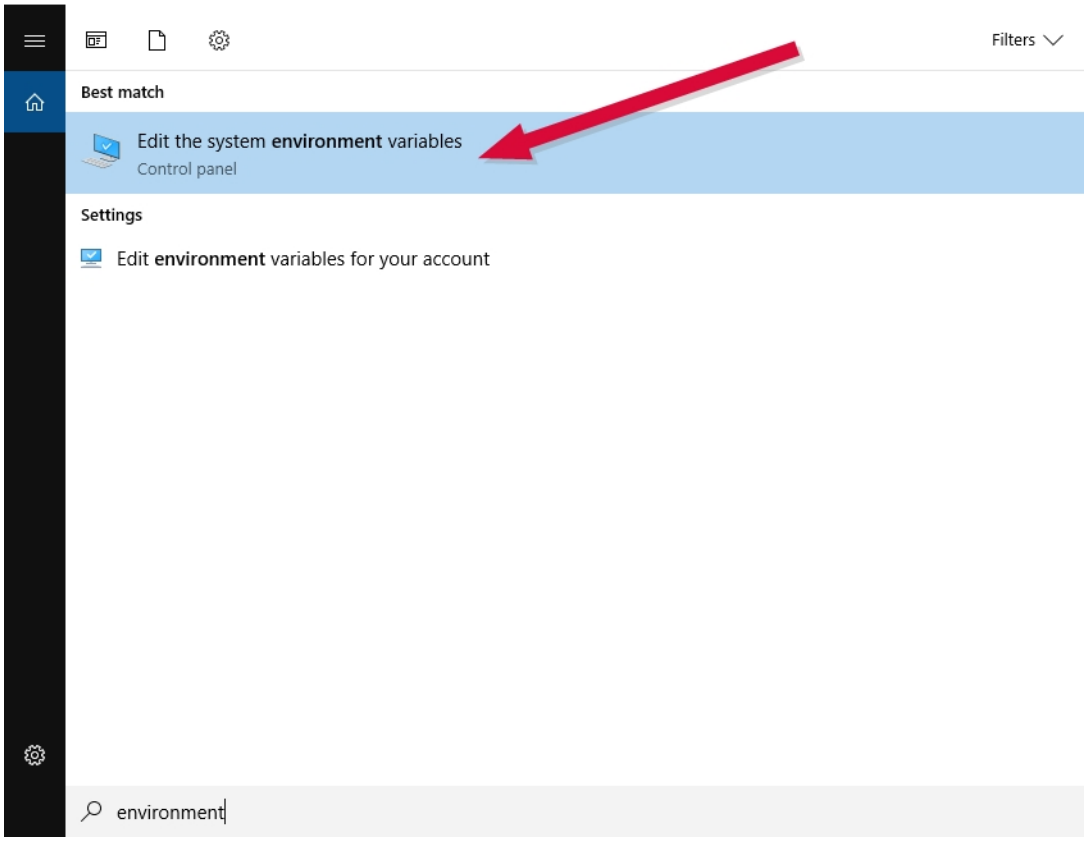

Figure 539: Search for System Environment Variables

5. In the System Properties dialog on the Advanced tab, click *Environment Variables*.

6. In the Environment Variables dialog in the *System variables* section at the bottom, scroll down to locate the *Path* variable, highlight it and click **Edit**.

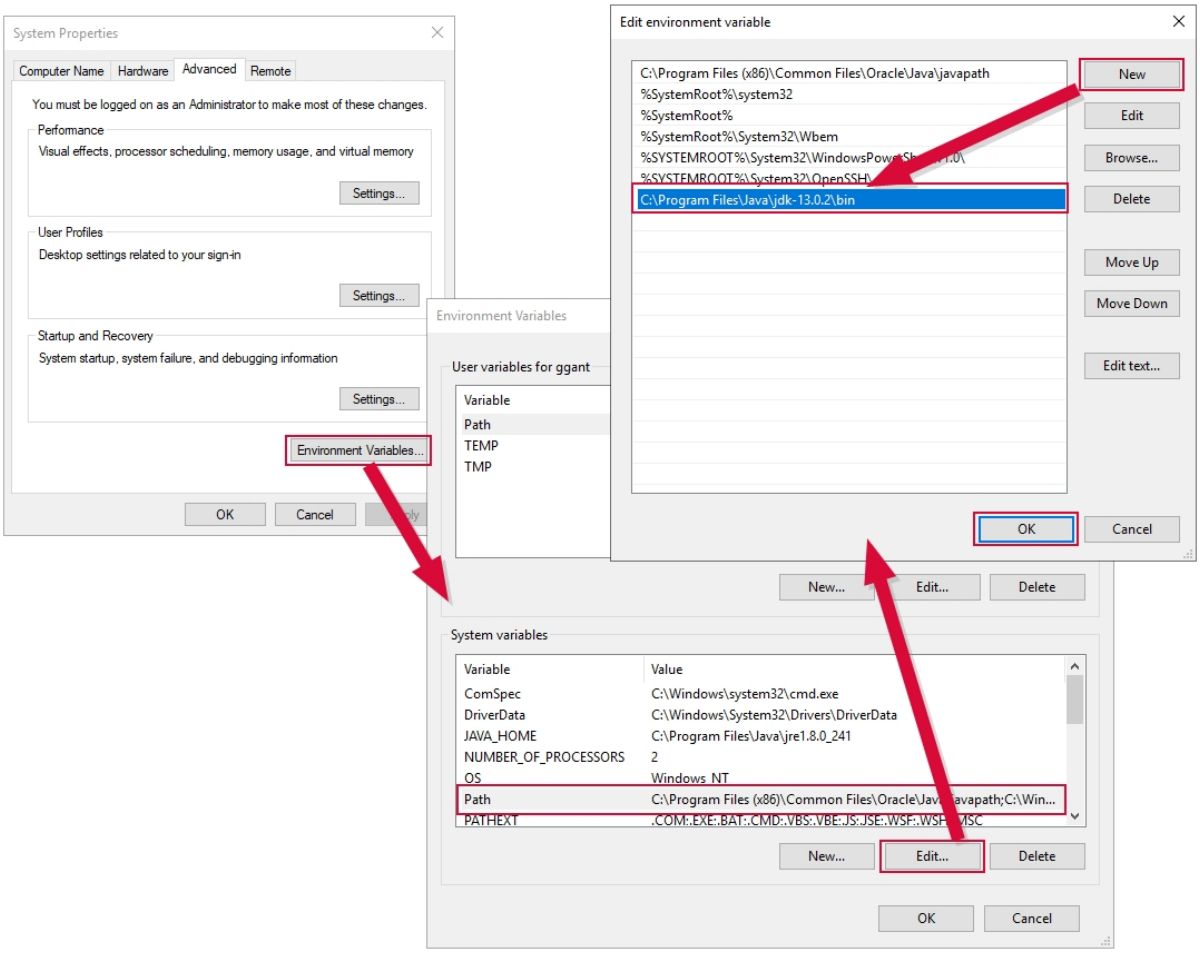

Figure 540: Edit the System Path Environment Variable to Add the Path to Java

7. In the Edit Environment Variable dialog, click **New**. On the newly added line, paste the path to the main Java executable (e.g. C:\Program Files\Java\jdk-13.0.2\bin) that you saved earlier (do not include the java.exe part) and click *OK*.

8. If it doesn't exist already among the *System variables*, create the JAVA_HOME environment variable—click **New** below the *System variables* box and, in the New System Variable dialog, type **JAVA_HOME** in the *Variable name* field and paste the path to the Java base directory in the *Variable value* field. If the field exists already but with a value that is not correct for the version of Java you wish to use, click **Edit** and update the *Variable value* field with the appropriate Java base directory.

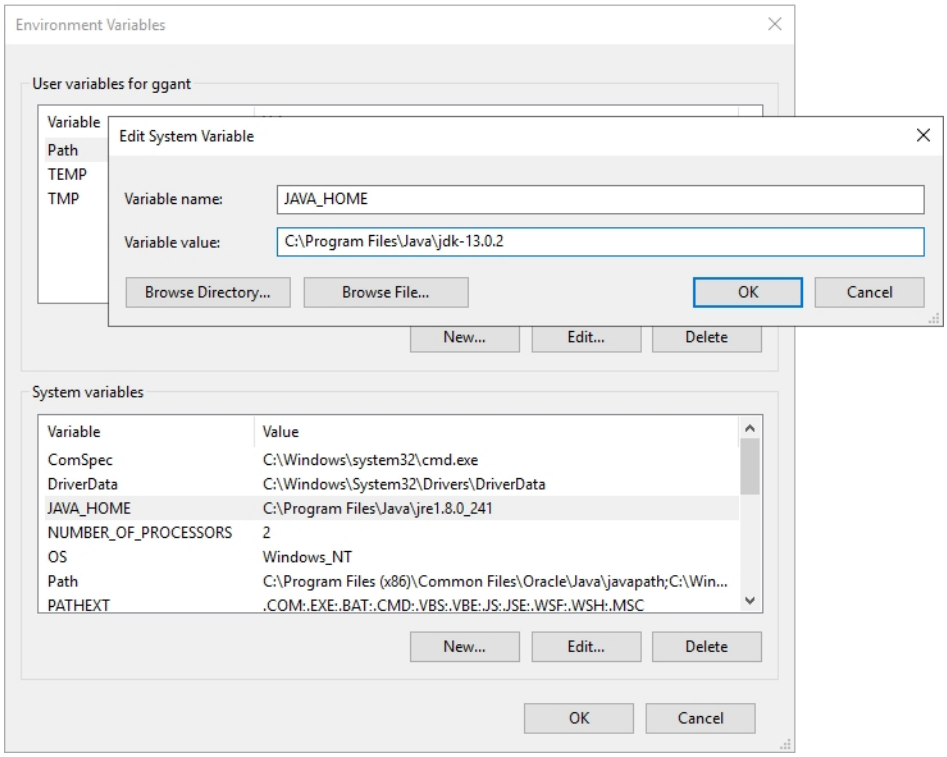

Figure 541: Add JAVA_HOME System Environment Variable

Important: When you run the install.ps1 script, you may be prompted to input the absolute path to the Java Virtual Machine library. From the text file in which you saved paths, take the path to the Java Virtual Machine library (e.g. C:\Program Files\Java\jdk-13.0.2\bin\server\jvm.dll) and input that string to complete the install.

5.3.2 Install the Java Agent on Windows

The Keyfactor Java Agent installation script offers the option to install the Java agent directly or use the installation script to build an msi package that you can then use to install the Java agent on multiple machines.

Note: If you have a previously installed version of the Keyfactor Java Agent on this server, you need to uninstall it (see Uninstall the Java Agent on page 2432) before installing a new version.

To begin the Java agent installation on Windows, unzip the installation files and place them in a temporary working directory.

1. On the Windows machine on which you wish to install the Java agent or build the package, open a PowerShell window using the "Run as administrator" option and change to the temporary directory where you placed the installation files.

2. In the PowerShell window, run the cms-java-agent-installer.bat file to begin the installation. You will be prompted to answer several questions:

Username the Java Agent will connect as

This is the service account on the Keyfactor Command server side of the fence you created as per Create Service Accounts for the Java Agent on page 2412. It should be entered in the format DOMAIN\username.

Password for the account that the Java Agent will connect as

This is the password for the service account on the Keyfactor Command server side of the fence.

Hostname or address for the Keyfactor Command Agents server

This is the FQDN or IP address of the Keyfactor Command server running the Keyfactor Command Agent Services role, which is installed as part of the Keyfactor Command Services role. If you installed all the Keyfactor Command server roles together, this is the FQDN or IP address of your Keyfactor Command server.

If you choose to use SSL to connect to the Keyfactor Command server, you'll need to enter a hostname at this prompt that is found in the SSL certificate.

If you're using a non-standard port for IIS on your Keyfactor Command server, enter that here as part of your hostname or IP address (e.g. keyfactor.keyexample.com:444).

Virtual directory for the Keyfactor Command Agents service URL

Press Enter to accept the default of KeyfactorAgents. Only enter an alternate virtual directory if your Keyfactor Command server was configured with an alternate virtual directory for the Keyfactor Command Agents service.

Connect to Keyfactor using SSL?

Press Enter to accept the default of Yes or enter No. The following instructions assume that you answered Yes.

To connect to Keyfactor Command, the Java Agent needs to trust the SSL certificate presented by the Keyfactor Command Agents server

If your Keyfactor Command server is using a publicly rooted certificate, the server most likely already trusts the certificate issuer, and you can press Enter here.

If the certificate on the Keyfactor Command server was internally generated, you will need to enter the full path and file name pointing to a file on the local server containing the PEM-encoded root certificate for the certificate authority chain that issued the certificate (see Configure Certificate Root Trust for the Java Agent on page 2414).

The root certificate will be saved in a Java keystore file called trust.jks located in the Java agent's install directory (C:\Program Files\Keyfactor\Keyfactor Java Agent by default). The default keystore password is "changeit". Please contact Keyfactor technical support for assistance in changing the default password, if desired.

This question will not appear if you answered no to the question about using SSL.

Verify Keyfactor Command connectivity?

Press Enter to accept the default of "Yes". The Java agent will attempt to connect to the Keyfactor Command server using the credentials provided to confirm that the server name, agents URL, root trust, and provided credentials are valid. Enter "No" to skip this validation if you don't have connectivity to the Keyfactor Command server at the time of installation.

Tip: If the installer terminates after this question without an error or with an error writing the trust.jks file, it can be an indication that the path to the root certificate you provided in the previous question was incorrect in some way (e.g. the path is not valid, the root certificate doesn't match the certificate on the Keyfactor Command server, etc.)

Please specify the installation format

The options at this prompt are "local" or "msi". If you press enter to accept "local", the Java agent will be installed locally. If you enter "msi", the batch file will generate an msi after all the questions have been answered. You can use this to install the Java agent on other Windows systems with the installation questions already answered. The subsequent questions differ depending on the answer given to this question. The following instructions include both local and msi questions. You will not see all of these questions.

If you select "msi", the Java agent will not be installed locally.

Path to the desired directory for installation (Local)

Press Enter to accept the default installation directory of C:\Program Files\Keyfactor\Keyfactor Java Agent or enter an alternate path if desired. This question does not appear when generating an msi.

Local user account the agent should run as \ User account on the target machine that the agent should run as (Local\MSI)

Press Enter to accept the default of the local SYSTEM account for local installs (this is not an option when generating an msi) or enter a specific user account—the service account for the Java agent side of the fence you created as per Create Service Accounts for the Java Agent on page 2412. Domain user accounts should be entered in the format DOMAIN\username. You do not need to enter the password for this user at this time. The username is entered at this time to allow permissions to be configured appropriately.

Hostname the agent will connect to Keyfactor as (Local)

Press Enter to accept the default of the local machine's hostname as determined by a reverse DNS lookup or, failing that, the value of the local environment variable for the computer name. If desired, you can enter an alternative value to use as the hostname. This is the identifier for the server on which you are installing the Java agent. This identifier can be in the form of a hostname or FQDN, but you can use another unique identifier, if desired. This identifier appears in the Keyfactor Command Management Portal on the orchestrators page. This question does not appear when generating an msi.

Tip: When installing from an msi, you can specify a custom hostname by using the AGENTNAME parameter. In order to use this option, you must install the msi from the command line. For example:

```
msiexec /i C:\temp\cms-java-agent.msi AGENTNAME=jvagnt38.keyexample.com
```

Note: If the agent machine has a non-private address, you will most likely need to use this option.

Directory where the agent logs should be placed (Local)

Press Enter to accept the default log directory of C:\CMS\logs or enter an alternate path if desired. This question does not appear when generating an msi.

Number of log files that should be kept (Local\MSI)

Press Enter to accept the default of 7 log files or enter an alternate number if desired. Older files are automatically deleted once more files than this have been generated.

Maximum size of each log file (Local\MSI)

Press Enter to accept the default log file size of 3 MB or enter an alternate value if desired.

Register AnyAgent components with the Keyfactor Java Agent? (Local)

Press Enter to accept the default value and begin the installation. If you would like to install one or more Any Agent implementations, enter yes. In this case, you'll be presented with a list of custom certificate store types for which to provide an implementation. After choosing each one, you'll need to enter the path to the .jar file that implements the certificate store type. That .jar file will be copied to the installation directory, under the libs folder. You'll need to manually copy any other dependent .jar files to that location as well. Note that this option is only available when the Java agent is installed locally. This question does not appear when generating an msi.

3. After answering the AnyAgent components question, the installation begins. Review the output to be sure that no errors have occurred and then press any key to return to the PowerShell prompt.

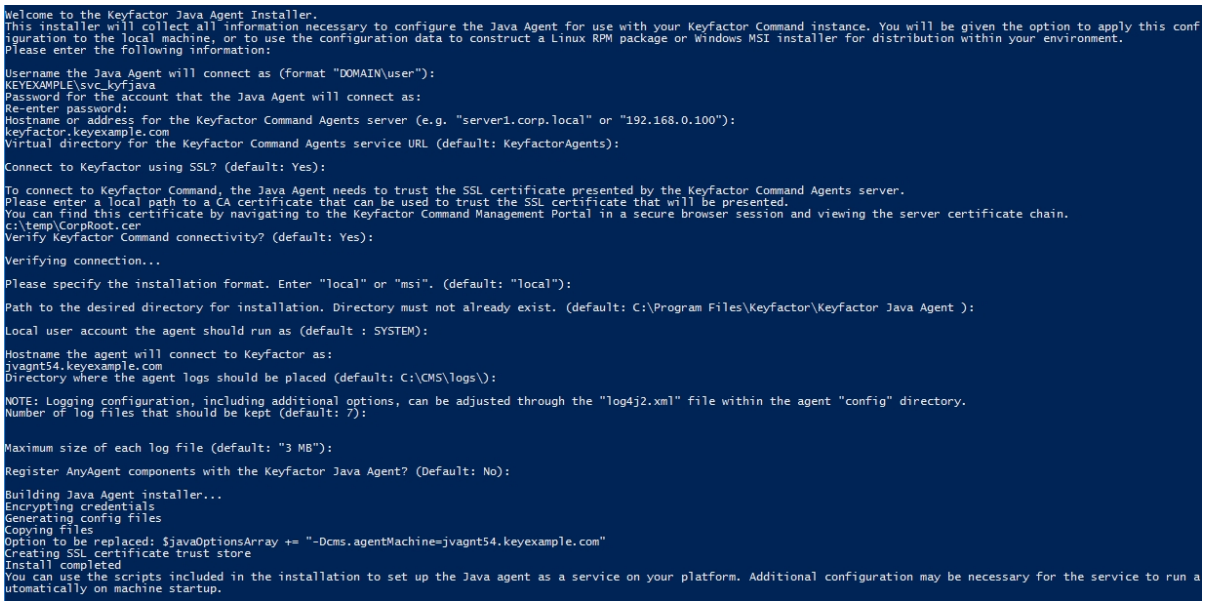

Figure 542: Keyfactor Java Agent Local Installation on Windows

4. In the PowerShell window, change to the install directory within the directory in which you installed the Java agent. If you installed in the default install directory, this path is:

   C:\Program Files\Keyfactor\Keyfactor Java Agent\install

5. In the PowerShell window, run the install.ps1 PowerShell script. Unless you selected SYSTEM as the user the agent should run as, you will be prompted to enter the username (DOMAIN\username format) and password of the account that will run the Keyfactor Java Agent service on the local machine. This is the service account for the Java agent side of the fence you created as per Create Service Accounts for the Java Agent on page 2412. Press Enter without entering any data to run the service under the local system credentials.

   Note: The install.ps1 may fail with an error similar to the following on older versions of Windows:

   ```
   Method invocation failed because [System.Object[]] doesn't contain a method named 'Replace'.
   ```

   If this occurs, you need to manually grant the service account under which the Keyfactor Java Agent service will run the local "Log on as a service" permission and then run the install.ps1 script again.

Tip: If you choose the "msi" option rather than the "local" option, the MSI file will be generated in the directory in which you executed the batch file.

5.3.3 Install the Java Agent on Linux

The Java Agent installation script offers the option to install the Java Agent directly or use the installation script to build an RPM package that you can then use to install the Java Agent on multiple machines.

Note: If you have a previously installed version of the Keyfactor Java Agent on this server, you need to uninstall it (see Uninstall the Java Agent on page 2432) before installing a new version.

To begin the Java Agent installation on Linux, unzip the installation files and place them in a temporary working directory.

1. On the Linux machine on which you wish to install the Java Agent or build the package, at a command shell change to the temporary directory where you placed the installation files.

2. Use the chmod command to make the cms-java-agent-Installer.sh script executable. The file ships in a non-executable state to avoid accidental execution. For example:

   ```
   sudo chmod +x cms-java-agent-installer.sh
   ```

3. In the command shell, run the cms-java-agent-Installer.sh script *as root* to begin the installation. You will be prompted to answer several questions:

   ## Username the Java Agent will connect as

   This is the service account on the Keyfactor Command server side of the fence you created as per Create Service Accounts for the Java Agent on page 2412. It should be entered in the format DOMAIN\username.

   ## Password for the account that the Java Agent will connect as

   This is the password for the service account on the Keyfactor Command server side of the fence.

   ## Hostname or address for the Keyfactor Command Agents server

   This is the FQDN or IP address of the Keyfactor Command server running the Keyfactor Command Agent Services role, which is installed as part of the Keyfactor Command Services role. If you installed all the Keyfactor Command server roles together, this is the FQDN or IP address of your Keyfactor Command server.

   If you choose to use SSL to connect to the Keyfactor Command server, you'll need to enter a hostname at this prompt that is found in the SSL certificate.

   If you're using a non-standard port for IIS on your Keyfactor Command server, enter that here as part of your hostname or IP address (e.g. keyfactor.keyexample.com:444).

   ## Virtual directory for the Keyfactor Command Agents service URL

   Press Enter to accept the default of KeyfactorAgents. Only enter an alternate virtual directory if your Keyfactor Command server was configured with an alternate virtual directory for the Keyfactor Command Agents service.

   ## Connect to Keyfactor using SSL?

   Press Enter to accept the default of Yes or enter No. The following instructions assume that you answered Yes.

To connect to Keyfactor Command, the Java Agent needs to trust the SSL certificate presented by the Keyfactor Command Agents server...

If your Keyfactor Command server is using a publicly rooted certificate, the server most likely already trusts the certificate issuer, and you can press Enter here.

If the certificate on the Keyfactor Command server was internally generated, you will need to enter the full path and file name pointing to a file on the local server containing the PEM-encoded root certificate for the certificate authority chain that issued the certificate (see Configure Certificate Root Trust for the Java Agent on page 2414).

The root certificate will be saved in a Java keystore file called trust.jks located in the Java Agent's install directory (/opt/keyfactor-java-agent by default). The default keystore password is "changeit". Please contact Keyfactor technical support for assistance in changing the default password, if desired.

This question will not appear if you answered no to the question about using SSL.

Verify Keyfactor Command connectivity?

Press Enter to accept the default of "Yes". The Java Agent will attempt to connect to the Keyfactor Command server using the credentials provided to confirm that the server name, agents URL, root trust, and provided credentials are valid. Enter "No" to skip this validation if you don't have connectivity to the Keyfactor Command server at the time of installation.

Tip: If the installer terminates after this question without an error or with an error writing the trust.jks file, it can be an indication that the path to the root certificate you provided in the previous question was incorrect in some way (e.g. the path is not valid, the root certificate doesn't match the certificate on the Keyfactor Command server, etc.)

Please specify the installation format

The options at this prompt are "local" or "rpm". If you press enter to accept "local", the Java Agent will be installed locally. If you enter "rpm", the script will generate an rpm after all of the questions have been answered. You can use this to install the Java Agent on other Linux systems with the installation questions already answered. The subsequent questions differ depending on the answer given to this question. The following instructions include both local and rpm questions. You will not see all of these questions.

If you select "rpm", the Java agent will not be installed locally.

Path to the desired directory for installation (Local)

Press Enter to accept the default installation directory of /opt/keyfactor-java-agent or enter an alternate path if desired. This question does not appear when generating an rpm.

Local user account the agent should run as \ User account on the target machine that the agent should run as (Local\RPM)

This is the service account for the Java Agent side of the fence you created as per Create Service Accounts for the Java Agent on page 2412. It should be entered as just the user name. Entry of the password for this service account is not required. The username is entered at this time to allow permissions to be configured appropriately.

Hostname the agent will connect to Keyfactor as (Local)

Press Enter to accept the default of the local machine's hostname as determined by a reverse DNS lookup or, failing that, the value of the local environment variable for the computer name. If desired, you can enter an alternative value to use as the hostname. This is the identifier for the server on which you are installing the Java agent. This identifier can be in the form of a hostname or FQDN, but you can use another unique identifier, if desired. This identifier appears in the Keyfactor Command Management Portal on the orchestrators page. This question does not appear when generating an rpm.

Full path to the desired buildroot directory for RPM package staging. Directory must not exist. (RPM)

Press Enter to accept the default path of /temp under the current directory or enter an alternate path if desired. This is a temporary location the build process will use while the package is being created. This is not the directory where the final RPM file will be placed. This question does not appear when installing locally.

Note: Ensure the path does not contain spaces. Any space in the java agent path causes issues when building an rpm.

Tip: The RPM file will be generated in a subdirectory (rpmbuild/RPMS) of the home directory of the user running the cms-java-agent-Installer.sh script. If you run the script as root, this will be root's home directory, so you may choose to run the script as a non-root user if you plan to create an RPM.

Path the RPM will install to on the target machine (RPM)

Press Enter to accept the default installation directory of /opt/keyfactor-java-agent or enter an alternate path if desired. This question does not appear when installing locally.

Architecture of the RPM target machine (RPM)

Press Enter to accept the default as determined by the machine on which the RPM is being generated or enter an alternate architecture if desired. A separate RPM needs to be generated with each required machine architecture. This question does not appear when installing locally.

Directory where the agent logs should be placed (Local\RPM)

Press Enter to accept the default log directory of /opt/cms-java-agent/logs or enter an alternate path if desired.

Number of log files that should be kept (Local\RPM)

Press Enter to accept the default of 7 log files or enter an alternate number if desired. Older files are automatically deleted once more files than this have been generated.

Maximum size of each log file (Local\RPM)

Press Enter to accept the default log file size of 3 MB or enter an alternate value if desired.

Register AnyAgent components with the Keyfactor Java Agent? (Local)

Press Enter to accept the default value and begin the installation. If you would like to install one or more Any Agent implementations, enter yes. In this case, you'll be presented with a list of custom certificate store types for which to provide an implementation. After choosing each one, you'll need to enter the path to the .jar file that implements the certificate store type. That .jar file will be copied to the installation directory, under the libs folder. You'll need to manually copy any other dependent .jar files to that location as well. Enter "Done" when you've finished listing agent implementations. Note that this option is only available when the JavaAgent is installed locally.

4. After answering the log file size question, the installation begins. Review the output to be sure that no errors have occurred.

```
Welcome to the Keyfactor Java Agent Installer.
This installer will collect all information necessary to configure the Java Agent for use with your Keyfactor Command instance. You will be given the option to a
pply this configuration to the local machine, or to use the configuration data to construct a Linux RPM package or Windows MSI installer for distribution within
your environment.
Please enter the following information:

Username the Java Agent will connect as (format "DOMAIN\user"):
KEYEXAMPLE\svc_kyfjava
Password for the account that the Java Agent will connect as:
Re-enter password:
Hostname or address for the Keyfactor Command Agents server (e.g. "server1.corp.local" or "192.168.0.100"):
keyfactor.keyexample.com
Virtual directory for the Keyfactor Command Agents service URL (default: KeyfactorAgents):

Connect to Keyfactor using SSL? (default: Yes):

To connect to Keyfactor Command, the Java Agent needs to trust the SSL certificate presented by the Keyfactor Command Agents server.
Please enter a local path to a CA certificate that can be used to trust the SSL certificate that will be presented.
You can find this certificate by navigating to the Keyfactor Command Management Portal in a secure browser session and viewing the server certificate chain.
/tmp/CorpRoot.crt
Verify Keyfactor Command connectivity? (default: Yes):

Verifying connection...

Please specify the installation format. Enter "local" or "rpm". (default: "local"):

Path to the desired directory for installation. Directory must not already exist. (default: /opt/keyfactor-java-agent ):

Local user account the agent should run as:
kyfuser

Hostname the agent will connect to Keyfactor as:
jvagnt162.keyexample.com
Directory where the agent logs should be placed (default: /opt/keyfactor-java-agent/logs/):

NOTE: Logging configuration, including additional options, can be adjusted through the "log4j2.xml" file within the agent "config" directory.
Number of log files that should be kept (default: 7):

Maximum size of each log file (default: "3 MB"):

Register AnyAgent components with the Keyfactor Java Agent? (Default: No):

Building Java Agent installer...
Encrypting credentials
Generating config files
Copying files
Creating SSL certificate trust store
Install completed
You can use the scripts included in the installation to set up the Java agent as a service on your platform. Additional configuration may be necessary for the se
rvice to run automatically on machine startup.
```

Figure 543: Keyfactor Java Agent Local Installation on Linux

5. Keyfactor provides scripts that can be used to configure the Keyfactor Java Agent to start automatically. These can be used on systems using startups based on SysV style (init.d) or systemd. Other startup systems will need to be configured manually. If your machine has neither of these startup systems, you will not be able to use these scripts to configure the Keyfactor Java Agent to start automatically. The appropriate startup script to use depends on whether you are doing a local install or installing from a previously generated RPM file.

Local Install

a. In the command shell, change to the directory in which you installed the Java Agent. The default install directory is:

   /opt/keyfactor-java-agent

b. Select the appropriate installation script for your startup system. The two available scripts for local installs are:

   ```
   install-init-service.sh
   install-systemd-service.sh
   ```

   Tip: The scripts with -with-configured-hostname in their names (e.g. install-systemd-service-with-configured-hostname.sh) are for use with installations from RPM packages and should not be used for local installs.

c. Use the chmod command to make the desired script executable. The file ships in a non-executable state to avoid accidental execution. For example:

```
sudo chmod +x install-systemd-service.sh
```

d. Run the appropriate shell script as root. This will add the keyfactor-java-agent as a service, which you can then stop and start using the standard service stop and start commands. For example:

```
service keyfactor-java-agent restart
systemctl restart keyfactor-java-agent.service
```

Install from RPM

a. Locate the RPM file on the machine on which it was generated and copy it to the machine on which you wish to install the Java agent.

> **Tip:** The RPM file is generated in a subdirectory (rpmbuild/RPMS) of the home directory of the user running the cms-java-agent-Installer.sh script. If you run the script as root, this will be root's home directory.

b. Execute the RPM as root. For example:

```
sudo rpm -ivh keyfactor-java-agent-8.6.0-1.i686.rpm
```

c. In the command shell, change to the directory in which you installed the Java Agent. The default install directory is:

```
/opt/cms-java-agent
```

d. There are four possible installation scripts for installation from RPM packages:

```
install-init-service.sh
install-init-service-with-configured-hostname.sh
install-systemd-service.sh
install-systemd-service-with-configured-hostname.sh
```

Select the appropriate installation script type for your startup system (init or systemd). The versions of the scripts that contain a reference to *with-configured-hostname* in the file name allow you to enter a custom agent name (see Hostname the agent will connect to Keyfactor as (Local) on page 2424). The versions without this reference will use the system hostname as the agent name.

e. Use the chmod command to make the desired script executable. The file ships in a non-executable state to avoid accidental execution. For example:

```
sudo chmod +x install-systemd-service-with-configured-hostname.sh
```

f. Run the appropriate shell script as root. You will be prompted to answer questions specific to the machine on which the Java agent is being installed—the hostname or other identifier for the machine (see Hostname the agent will connect to Keyfactor as (Local) on page 2424) if you used a *with-*

configured-hostname script and the username and password for the service account that will connect the agent to Keyfactor Command (see Username the Java Agent will connect as on page 2422).

g. Change the ownership on the file containing the startup credentials to the local user that the agent will run as. This file is found in the *config* directory under the installed directory and is called *install.creds*. For example:

```
sudo chown kyfuser /opt/cms-java-agent/config/install.creds
```

h. The install shell script adds the keyfactor-java-agent as a service, which you can then stop and start using the standard service stop and start commands. You may need to restart the service after changing the ownership on the credentials file. For example:

```
service keyfactor-java-agent restart
systemctl restart keyfactor-java-agent.service
```

Tip: If desired, you can pass the responses to the questions the installer asks in from a file. For example, for a full install (not working from an RPM file you previously created), create a file that contains values something like this:

```
KEYEXAMPLE\svc_kyfjava
MyVerySecurePassword
MyVerySecurePassword <- The installer requires entry of the password twice
keyfactor.keyexample.com
KeyfactorAgents
Yes
/tmp/CorpRoot.crt
Yes
local
/opt/keyfactor-java-agent
kyfuser
jvagnt162.keyexample.com
/opt/keyfactor-java-agent/logs
7
"3 MB"
No
```

Note that the values needed in your input file will vary depending on how you answer some of the questions. For example, the first Yes shown above will go in response to the question of whether to use SSL for the connection to Keyfactor Command. If you answer No here, you will not receive the question about needing a root certificate, and so the path to a root certificate shown after this will not correctly match the next question. The script will fail.

Place the file in the same directory as the install script. Then, execute the install script like this:

```
sudo ./cms-java-agent-installer.sh < myinputfile.txt
```

5.3.4 Optional Configuration

Once the installation scripts are complete, the Java Agent should be running and ready to communicate with the Keyfactor Command server.

Important: Java Agent tasks will not run until you complete the Java Agent configuration by making the appropriate configuration changes in the Keyfactor Command Management Portal. See Orchestrators on page 444 in the *Keyfactor Command Reference Guide* for instructions on approving the Java Agent in the Keyfactor Command Management Portal on the *Orchestrators->Auto-Registration* and *Orchestrators->Management* pages, and on configuring certificate stores on the *Certificate Management->Certificate Stores* page (see Adding or Modifying a Certificate Store on page 363 and Certificate Store Discovery on page 400 in the *Keyfactor Command Reference Guide*).

5.3.4.1 Configure Logging for the Java Agent

By default, the Java Agent places its log files in the C:\CMS\logs directory on Windows and the /opt/keyfactor-java-agent/logs directory on Linux, generates logs at the "Info" logging level and stores seven 3 MB logs before deleting them (how long this will be will depend on the logging level and the volume of usage the Java Agent is receiving).

If you wish to change these defaults after the installation is complete on Windows:

1. On the Java Agent machine where you wish to adjust logging, open a text editor (e.g. Notepad) using the "Run as administrator" option.

2. In the text editor, browse to open the log4j2.xml file in the config directory under the directory in which you installed the Java Agent. By default, the file is located in the following directory:
   C:\Program Files\Keyfactor\Keyfactor Java Agent\config

3. Your log4j2.xml file may have a slightly different layout than shown here, but it will contain the four fields highlighted in the below figure. The fields you may wish to edit are:

   - fileName="C:\CMS\logs\CMS-Java.txt"

     The path and file name of the active Java Agent log file.

     Important: If you choose to change the path for storage of the log files, you will need to create the new directory (e.g. D:\KeyfactorLogs) and grant the service account under which the Keyfactor Java Agent service is running full control permissions on this directory.

   - size="3 MB"
     The maximum file size of each log file. After a log file reaches the maximum size, it is rotated to an archive file name and a new log file is generated.
   - max="7"
     The number of archive files to retain before deletion.
   - level="info"
     The level of log detail that should be generated. The default "info" level logs error and some informational data but at a minimal level to avoid generating large log files. For troubleshooting, it may be

desirable to set the logging level to "debug" or "trace". Available log levels (in order of increasing verbosity) are:

- OFF – No logging
- FATAL – Log severe errors that cause early termination
- ERROR – Log severe errors and other runtime errors or unexpected conditions that may not cause early termination
- WARN – Log errors and use of deprecated APIs, poor use of APIs, "almost" errors, and other runtime situations that are undesirable or unexpected but not necessarily "wrong"
- INFO – Log all of the above plus runtime events (startup/shutdown)
- DEBUG – Log all of the above plus detailed information on the flow through the system
- TRACE – Maximum log information—this option can generate VERY large log files

```
  <RollingFile name="logfile" fileName="C:\CMS\logs\CMS-Java.txt" filePattern="CMS-Java-%i.txt">
    <PatternLayout pattern="%d{yyyy-MM-dd HH:mm:ss.SSS} [%t] %-5level %logger{36} - %msg%n" />
    <MarkerFilter marker="EVENT" onMatch="DENY" onMismatch="NEUTRAL" />
    <SizeBasedTriggeringPolicy size="3 MB"/>
    <DefaultRolloverStrategy max="7"/>
  </RollingFile>
  Section of file removed in graphic for simplicity.
<Loggers>
  <Root level="info">
    <AppenderRef ref="console" />
    <AppenderRef ref="logfile" />
```

Figure 544: Configure Logging for Keyfactor Java Agent on Windows

If you wish to change these defaults after the installation is complete on Linux:

1. On the Java Agent machine where you wish to adjust logging, open a command shell and change to the directory in which the Java Agent is installed. By default this is /opt/keyfactor-java-agent.

2. In the command shell in the directory in which the Java Agent is installed, change to the config directory.

3. Using a text editor, open the log4j2.xml file in the config directory. Your log4j2.xml file may have a slightly different layout than shown here, but it will contain the four fields highlighted in the below figure. The fields you may wish to edit are:

   - fileName="/opt/keyfactor-java-agent/logs/CMS-Java.txt"

     The path and file name of the active Java Agent log file.

     Important: If you choose to change the path for storage of the log files, you will need to create the new directory (e.g. /opt/javalogs) and grant the service account under which the Keyfactor Java Agent service is running full control permissions on this directory.

   - size="3 MB"
     The maximum file size of each log file. After a log file reaches the maximum size, it is rotated to an archive file name and a new log file is generated.
   - max="7"
     The number of archive files to retain before deletion.

- level="info"
  The level of log detail that should be generated. The default "info" level logs error and some informational data but at a minimal level to avoid generating large log files. For troubleshooting, it may be desirable to set the logging level to "debug" or "trace". Available log levels (in order of increasing verbosity) are:
    - OFF – No logging
    - FATAL – Log severe errors that cause early termination
    - ERROR – Log severe errors and other runtime errors or unexpected conditions that may not cause early termination
    - WARN – Log errors and use of deprecated APIs, poor use of APIs, "almost" errors, and other runtime situations that are undesirable or unexpected but not necessarily "wrong"
    - INFO – Log all of the above plus runtime events (startup/shutdown)
    - DEBUG – Log all of the above plus detailed information on the flow through the system
    - TRACE – Maximum log information—this option can generate VERY large log files

```
<RollingFile name="logfile" fileName="/opt/cms-java-agent/logs/CMS-Java.txt" filePattern="CMS-Java-%i.txt">

Figure 545: Configure Logging for Keyfactor Java Agent on Linux

5.3.4.2 Start the Keyfactor Java Agent Service

The Keyfactor Java Agent service runs on the Java Agent machine and controls discovery, inventory and certificate store update tasks. During the Java Agent configuration process you set the service account under which the Keyfactor Java Agent service will run. The service should start automatically at the conclusion of the installation scripts.

To check to see if the Keyfactor Java Agent service is running and start it if necessary on Windows:

1. On a Windows Java Agent server, open the Services MMC.
2. In the Services MMC confirm that the Keyfactor Java Agent service is set to a Startup Type of Automatic (if desired). If the service is not running, click the green arrow to start it.

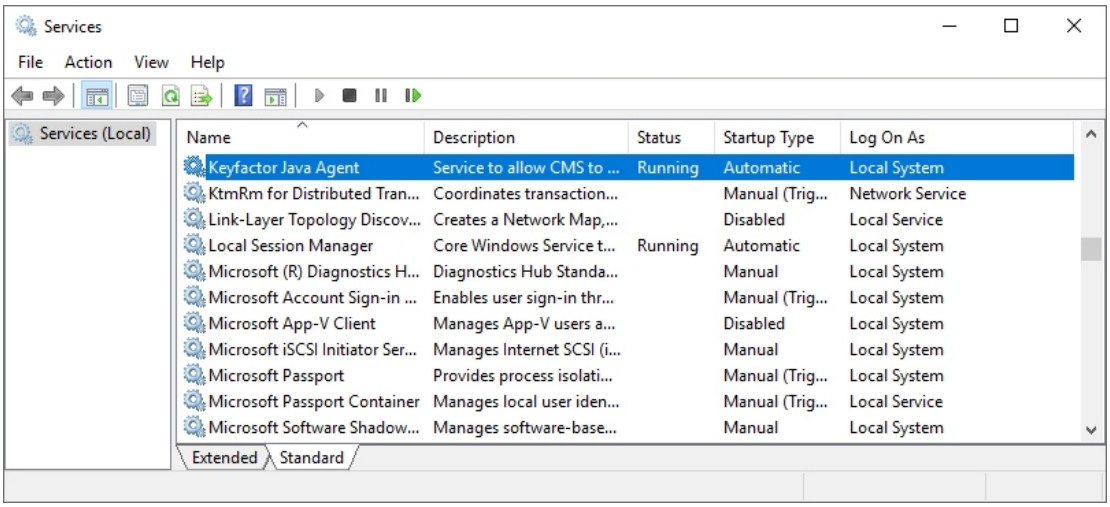

Figure 546: Keyfactor Java Agent Service on Windows

Service startup and shutdown procedures vary by Linux implementation and version depending on the startup system. The service on Linux is added as keyfactor-java-agent, so when referencing it in startup commands, it should be referenced by this name, including case. For example:

```
service keyfactor-java-agent start [stop] [restart]
systemctl start [stop] [restart] [status] keyfactor-java-agent.service
```

Once you have finished the Java keystore and PEM certificate store inventory configuration using the Keyfactor Command Management Portal and have imported certificates from the stores, you can use the Certificate Search feature in the Keyfactor Command Management Portal to review the certificate store certificates. See Certificate Search and Collections on page 18 in the *Keyfactor Command Reference Guide* for information on using the Certificate Search feature.

5.3.4.3 Uninstall the Java Agent

To uninstall the Java Agent on Linux.

1. On the Linux machine on which the Java Agent is installed, run the command to stop the service.

   ```
   sudo systemctl stop keyfactor-java-agent.service
   ```

2. Run the command to remove the service

   ```
   sudo systemctl disable keyfactor-java-agent.service
   ```

3. After steps 1 & 2 are executed, it is safe to manually remove the Java Agent folder (default location is /opt/keyfactor-java-agent/).

5.4 Bash Orchestrator

SSH supports a wide variety of authentication mechanisms. Often, enterprises fall back to simple username and password at least some of the time due to the complexities of key management for key-based authentication. Without key management, SSH keys tend to multiply, and you can quickly lose track of who has access to what where. The Keyfactor Bash Orchestrator is designed to allow organizations to inventory and manage secure shell (SSH) keys across the enterprise.

Important: SSH Key Management licensing is required to use any of the functionality outlined in the Keyfactor Bash Orchestrator documentation. Contact support@keyfactor.com for assistance with obtaining the proper licenses.

The orchestrator runs on Linux servers and can be operated in two possible modes:

- The orchestrator is used in *inventory only* mode to perform discovery of SSH public keys and associated Linux user accounts across multiple configured targets. When used in *inventory and publish policy* mode, the orchestrator:
  - Scans the authorized_keys files of all current users on each configured server.

    Note: OpenSSH maintains a file for each user that contains the public keys authorized to connect via SSH. By default, this file is named authorized_keys. In this document, we refer to this file as *authorized_keys*, however in your environment, this file may have a different name. The file name used in a given environment is defined in the AuthorizedKeysFile setting in the OpenSSH sshd_ config file.

  - Aggregates all public key data per Linux user logon.
  - Reports aggregate key and logon data back to Keyfactor Command.

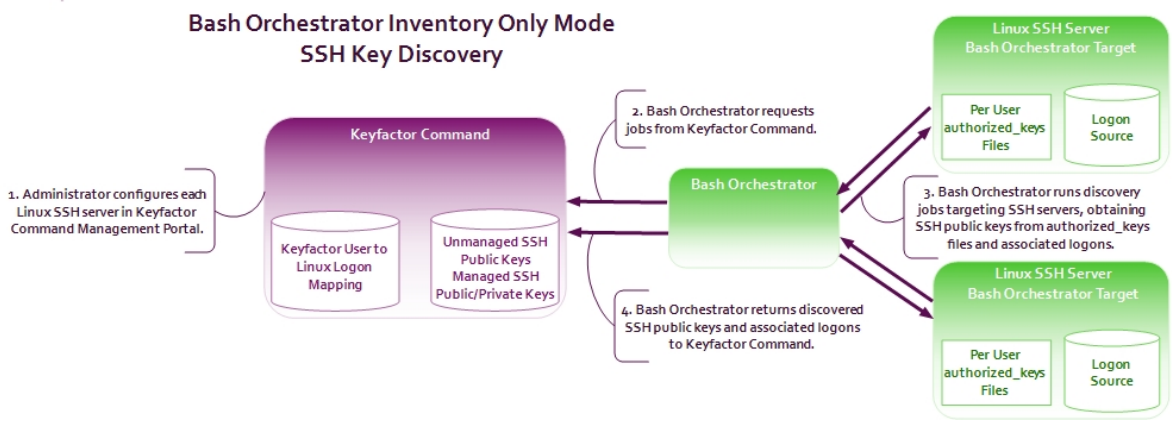

Figure 547: SSH Key Discovery Flow

- When operated in *inventory and publish policy* mode, the orchestrator can be used to add SSH public keys and Linux user accounts on targets and remove rogue keys that appear without authorization. Figure 548: SSH User Key Management Flow shows the flow from a user requesting a new key pair to the public key being

placed on a target server to allow the user to connect to the server via SSH. The flow is similar for requesting a key pair for a service, though the request is made by an administrator through a different interface in the Keyfactor Command Management Portal. When used in *inventory and publish policy* mode, policies are published to the orchestrator from the Keyfactor Command server following this flow:

- The Keyfactor Command server determines what content needs to go into the authorized_keys files for each logon on each target server. Content includes keys and associated comments aggregated from all servers where that key was found. For example, if a given public key exists on three different servers for the same user but in the original authorized_keys files the key is associated with a different comment on each server, when Keyfactor Command publishes the key down to the servers, it will be published with an aggregated comment string (all three comments together in each authorized_keys file).
- Aggregate logon and key information pushed down to each orchestrator target.
- Orchestrator determines where to place key information, builds the file, and overwrites the existing file with the new one. The process is done in this way to enforce policy and prevent rogue keys from being placed in authorized_keys files.
- Orchestrator informs Keyfactor Command of the success or failure of each machine logon combination.

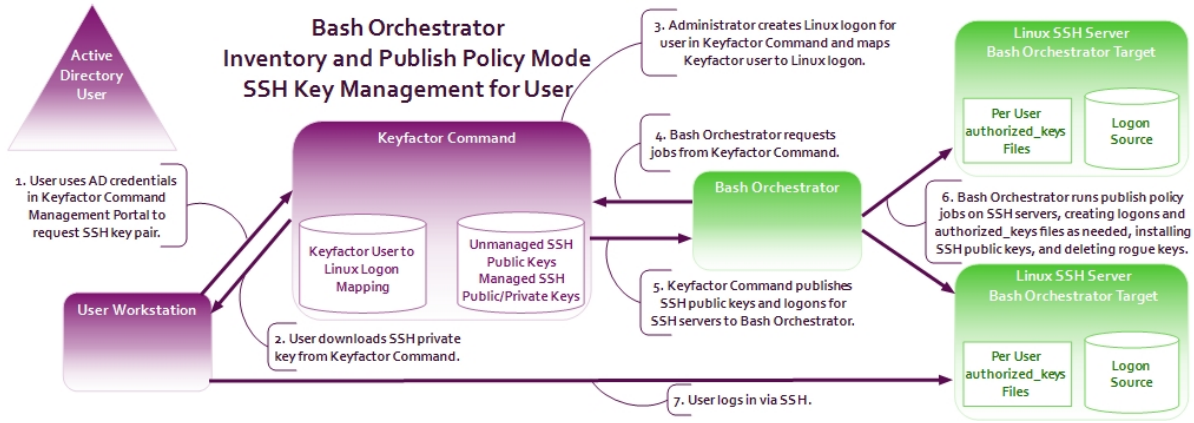

Figure 548: SSH User Key Management Flow

5.4.1 Preparing for the Keyfactor Bash Orchestrator

This section describes the steps that need to be taken prior to a Keyfactor Bash Orchestrator installation to install the prerequisites, create the required supporting components, and gather the necessary information to complete the orchestrator installation and configuration process.

5.4.1.1 System Requirements

The Keyfactor Bash Orchestrator is supported on the following operating systems:

- Oracle Linux 7 or higher
- Red Hat Enterprise 7 or higher
- Ubuntu 16 or higher

The minimum specs are:

- 2GB RAM
- 1 2GHz Processor
- 20GB disk space

Note: As more servers are added to be orchestrated by the orchestrator, increasing those specs will improve performance.

The following applications are required:

systemd

The orchestrator requires a Linux server that uses the systemd service manager. You can use the following command to test whether a system is running systemd:

```
ps -p 1
```

bash

The orchestrator can only be installed on a Linux server that is running bash version 4.3 or higher. You can use the following command to check the bash version of a server:

```
bash --version
```

For systems running an older version of bash, you may be able to successfully operate these as control targets (see Install Remote Control Targets on page 2441).

Note: The default version of bash on Red Hat Enterprise 7 is 4.2. If you're using this platform and your bash version has not already been updated, this will need to be done.

curl

The orchestrator can only be installed on a Linux server that has curl installed. You can use the following command to check the curl version of a server:

```
curl --version
```

This is a requirement for orchestrators only; curl does not need to be installed on control targets (see Install Remote Control Targets on page 2441).

5.4.1.2 Create a Service Account for the Keyfactor Bash Orchestrator

The Keyfactor Bash Orchestrator uses a service account in the Active Directory domain where the Keyfactor Command server resides to allow it to communicate with Keyfactor Command. This can be the same service account used for other Keyfactor Command server services. This service account appears in the Management Portal as the *Identity* on the Orchestrator Management grid for the Keyfactor Bash Orchestrator.

The service account needs to be created prior to installation of the Keyfactor Bash Orchestrator software, and the person installing the Keyfactor Bash Orchestrator software needs to know the domain, username and password of the service account.

During installation of the orchestrator, a local Linux user account is created automatically as an identity under which the orchestrator service will operate. This allows the orchestrator to run as a non-root user. On servers on which you install the orchestrator directly, the following Linux user account is created:

keyfactor-bash

On servers configured as remote control targets, the following Linux user account is created:

keyfactor-bash-orchestrator-svc

These users are granted access to read authorized_keys files for inventory purposes and to update authorized_keys files when the orchestrator is operating in *inventory and publish policy* mode using sudo. On install, modifications are made to the sudo configuration with the addition of a file in the /etc/sudoer.d directory granting the orchestrator user select sudo rights. The commands the service account user may be granted the right to use via sudo include:

```
adduser, awk, cat, chmod, chown, flock, gpasswd, ls, mkdir, restorecon, rm, sed, tee, test, touch, usermod
```

5.4.1.3 Create a Group for Auto-Registration (Optional)

Keyfactor Command can use an Active Directory group to support auto-registration of Keyfactor Bash Orchestrator. Auto-registration is an optional feature that allows you to define the conditions under which a Keyfactor Bash Orchestrator can automatically be approved for operation with the Keyfactor Command server without administrator input, if desired. This is useful in environments hosting a large number of orchestrators or if you wish to automatically add orchestrators to server groups and add them as servers in the Management Portal as you install them. The auto-registration role used by the Keyfactor Bash Orchestrator is called *Secure Shell Management*.

Add the service account or service accounts under which the orchestrators will communicate with Keyfactor Command to this group.

Note: If all your orchestrators will be connecting to Keyfactor Command as the same service account, you can directly add that user in the auto-registration configuration and skip using a group, if desired. Although you can choose to enable auto-registration without user validation, allowing any orchestrator to register regardless of the user account under which the orchestrator is running, user validation with either an Active Directory group or a specific Active Directory user is the more secure option.

5.4.1.4 Certificate Root Trust for the Keyfactor Bash Orchestrator

Keyfactor recommends using HTTPS to secure the channel between each Keyfactor Bash Orchestrator and the Keyfactor Command server(s). This requires an SSL certificate configured in IIS on the Keyfactor Command server (s). This certificate can either be a publicly-rooted certificate (e.g. from Symantec, Entrust, etc.), or one issued from a private certificate authority (CA). If your Keyfactor Command server is using a publicly rooted certificate, the orchestrator machine may already trust the certificate root for this certificate. However, if you have opted to use an internally-generated certificate, your orchestrator server may not trust this certificate. In order to use HTTPS for communications between the orchestrator and the Keyfactor Command server with a certificate generated from a private CA, you will need to import the certificate chain for the certificate into the orchestrator's root certificate

store. This can be done automatically as part of the installation process. You will need to have the root certificate available as a PEM-encoded format file when you run the installation script.

5.4.2 Install the Keyfactor Bash Orchestrator

To begin the Keyfactor Bash Orchestrator installation, place the installation files in a temporary working directory on the Linux server and:

1. On the Linux machine on which you wish to install the main orchestrator, in a command shell change to the temporary directory where you placed the installation files.

2. Use the chmod command to make the following script files executable. The files ship in a non-executable state to avoid accidental execution.
    - [yourpath]/heartbeat.sh
    - [yourpath]/static-analysis.sh
    - [yourpath]/syncjob.sh
    - [yourpath]/Service/keyfactor-bash-orchestrator.sh
    - [yourpath]/Service/systemd/configure-systemd.sh
    - [yourpath]/Service/systemd/stop.sh
    - [yourpath]/Installation/install.sh
    - [yourpath]/Installation/remoteinstall.sh
    - [yourpath]/Installation/uninstall.sh

    For example, this command will add the executable flag to every file with a .sh extension in the /tmp/BashOrchestrator directory and all its sub-directories:

    ```
    sudo find /tmp/BashOrchestrator -type f -iname "*.sh" -exec chmod +x {} \;
    ```

3. In the command shell, run the Installation/install.sh script as root using the following syntax to begin the installation:

-n, --username <*service account name*>

This is the service account that the orchestrator uses to communicate with Keyfactor Command that you created as per Create a Service Account for the Keyfactor Bash Orchestrator on page 2435. It should be entered in the format username@domain (e.g. svc_sshorch@keyexample.com). This parameter is required.

-u, --url <*Keyfactor Command agents URL*>

This is the URL to the Agent Services endpoint on the Keyfactor Command server running the Keyfactor Command Agent Services role, which is installed as part of the Keyfactor Command Services role. If you installed all the Keyfactor Command server roles together, this is the URL for your Keyfactor Command server with /KeyfactorAgents after the server's IP or FQDN (e.g. https://key-factor.keyexample.com/KeyfactorAgents). If you choose to use SSL to connect to the Keyfactor Command server, you'll need to enter a URL that contains a hostname that is found in the SSL certificate. This parameter

is required.

Tip: If your Keyfactor Command server was configured with an alternate virtual directory for the Keyfactor Command Agents Services endpoint, you will need to enter that in the URL rather than /KeyfactorAgents.

-p, --password <*your-secure-password*>

This is the password for the orchestrator service account. If you leave this parameter out, you will be prompted to enter this password.

-s, --ssl

Specifying this parameter causes the orchestrator to use SSL for communications with Keyfactor Command. Leave out this parameter if you prefer not to use SSL. This parameter does not take any arguments.

-t, --trusted-root </*path/root-filename*>

If your Keyfactor Command server is using a publicly rooted certificate, you do not need to use this option. If the certificate on the Keyfactor Command server was internally generated, you will need to use this option to specify the full path and file name of the file containing the root certificate for the certificate authority that issued the certificate (e.g. -t /tmp/myroot.crt). See Certificate Root Trust for the Keyfactor Bash Orchestrator on page 2436.

-i, --server-group-id <*GUID of existing SSH server group*>

If desired, you may specify this parameter to automatically add the server to an existing server group in Keyfactor Command. The server group must be specified by group ID (e.g. -i 74a9afcc-087d-423a-a331-06686427fdd9). You can find a server group's ID by editing the server group record in the Keyfactor Command Management Portal. This function is only supported if you have enabled auto-registration for SSH (see Create a Service Account for the Keyfactor Bash Orchestrator on page 2435).

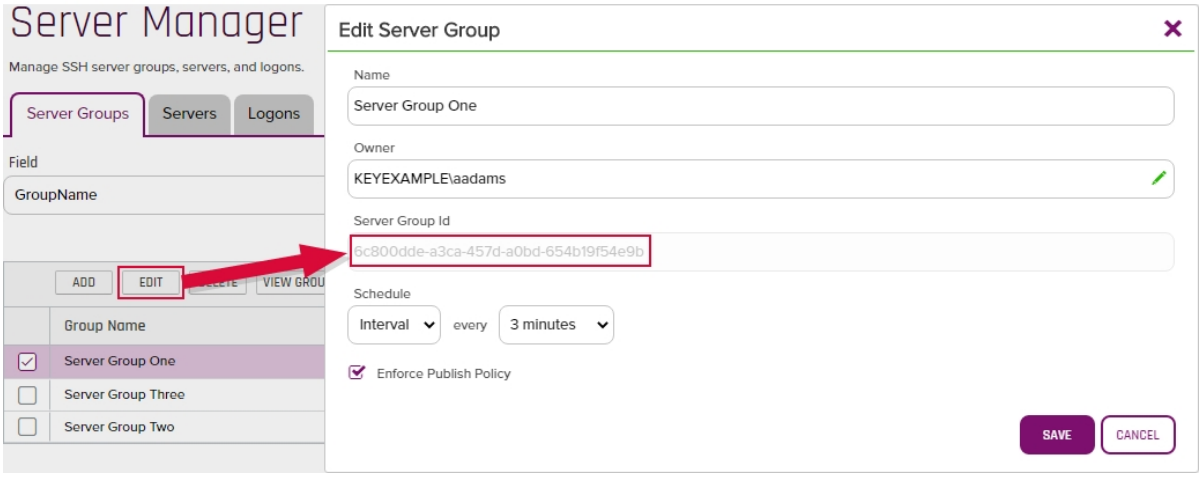

Figure 549: Find the Server Group ID

-c, --client-machine-name <*client name*>

Specifying this parameter allows you to override the client name the orchestrator would by default use to register itself in Keyfactor Command. By default, the orchestrator uses the results from a hostname lookup for the server's name. See the example output below where the name passed into Keyfactor Command (appsrvr80-SSH.ubuntu.keyexample.com) differs from the name used in the SSH key comment for the local Linux user (appsrvr80.keyexample.com).

-d, --use-sssd

This is required. You must explicitly specify whether or not you want to enable the orchestrator to use SSSD for user lookups.

- To enable SSSD set either:

```
-d true
--use-sssd true
```

- To disable SSSD set either:

```
-d false
--use-sssd false
```

When enabled, the orchestrator will check both the local user store and the SSSD user store (e.g. Active Directory) on requests to create logons and distribute key information, allowing keys to be managed both for local users and for domain users. When enabled, user logon must be created in Keyfactor Command with the username as it appears in SSSD (see SSH-SSSD Case Sensitivity Flag on page 661 and Adding Logons on page 538).

If you're using SSSD, you must be using SSSD on any remote servers the orchestrator will manage. Additionally, the *LogonHomeDirectories* setting is expected to be consistent on all remote servers.

Domain users can be managed with or without preexisting home directories.

-l, --logon-home-directories </*homedirectoryroot*>

Specifying this parameter allows you to set the base path for home directories of SSH users. This is referenced both when new logons are created, as requested through Keyfactor Command, and when doing discovery for existing logons and keys. If you don't specify a value, the default of */home* is used.

The value set for the Keyfactor Bash Orchestrator *login-home-directories* needs to match the value set for the path in the *override_homedir* or *fallback_homedir* SSSD configuration. For example, if *fallback_homedir* = /home/my/dir/path/%u@%d, *login-home-directories* needs to be set to /home/my/dir/path. All SSSD logons to be discovered by or created with the Keyfactor Bash Orchestrator must have a home directory in this directory, not a subdirectory of this directory. For example, given the previously referenced directory, the path /home/my/dir/path/myusername@keyexample.com would be valid but /home/my/dir/path/an-otherdirlevel/myusername@keyexample.com would not be valid. Home directories are created automatically when logons are created.

Important: Any remotely controlled targets (see Install Remote Control Targets on the next page) of a server using SSSD logons with the Keyfactor Bash Orchestrator must also be configured for SSSD logons and must have the same configuration value for *fallback_homedir* or *override_homedir*.

The output from the command should look similar to the following, given the example command shown.

```
sudo ./install.sh -u https://keyfactor.keyexample.com/KeyfactorAgents -n svc_
sshorch@keyexample.com -s -t /tmp/MyRoot.crt -i 74a9afcc-087d-423a-a331-06686427fdd9 -c
appsrvr80-SSH.ubuntu.keyexample.com -d false

4. Review the output from the installation to confirm that no errors have occurred.

The script creates a directory, /opt/keyfactor-bash-orchestrator, and places the orchestrator files in this directory. Log files are found in /opt/keyfactor-bash-orchestrator/logs, though this is configurable (see Configure Logging for the Keyfactor Bash Orchestrator on page 2443).

The orchestrator service, named keyfactor-bash-orchestrator.service, should be automatically started at the conclusion of the install and configured to restart on reboot.

Tip: Once the installation of the orchestrator and any targets for it to control is complete, you need to use the Keyfactor Command Management Portal to approve the orchestrator (if you don't have auto-registration for Keyfactor Bash Orchestrators enabled) and configure SSH server groups and servers as per Server Manager on page 513 in the *Keyfactor Command Reference Guide*. SSH server records are automatically created for the main bash orchestrator if you enable auto-registration for bash orchestrators and use the -i switch when registering the bash orchestrator. They are not automatically created for remote targets.

5.4.3 Install Remote Control Targets

After you complete the installation of at least one Keyfactor Bash Orchestrator, you can configure other Linux servers in the environment as control targets for this orchestrator. This is done by running a script on the target servers that installs the SSH public key matching the orchestrator's private key on the target server, along with making a few configuration changes. This allows the orchestrator service on the orchestrator (the local Linux user keyfactor-bash) to communicate with the targets using secured SSH.

Important: Any remotely controlled targets of a server using SSSD logons with the Keyfactor Bash Orchestrator must also be configured for SSSD logons and must have the same configuration value for *fallback_homedir* or *override_homedir*.

To configure orchestrator targets:

1. On the orchestrator machine, locate the remoteinstall.sh script in the /opt/keyfactor-bash-orchestrator directory. Do not use the remoteinstall-template.sh script found in the source material under Installation. This script has not been modified to contain the specific public key of your orchestrator.

   Tip: A copy of the configured remoteinstall.sh script may also be found in the directory from which you executed the installation of the Keyfactor Bash Orchestrator.

2. Copy the customized remoteinstall.sh script to the orchestrator target that you wish to configure and place it in a temporary working directory.

3. On the Linux machine you wish to control with the orchestrator, in a command shell change to the temporary directory where you placed the remoteinstall.sh script.

4. Use the chmod command to make the script file executable. The file ships in a non-executable state to avoid accidental execution. For example:
   ```
   sudo ./chmod +x remoteinstall.sh
   ```

5. In the command shell, run the remoteinstall.sh script as root with no parameters. There is no output from the command when it completes successfully.
   ```
   sudo ./remoteinstall.sh
   ```

The script creates a directory, /opt/keyfactor-bach-orchestrator-client, and places the public key of the orchestrator Linux service account user in an authorized_keys file within it. It also creates a local service account user (see Create a Service Account for the Keyfactor Bash Orchestrator on page 2435) and grants this user ownership on this file to allow the orchestrator server service account to perform tasks on the target.

Log messages are written to the standard Linux syslog. The location of these will vary depending on the system OS.

Tip: Once the installation of the orchestrator and any targets for it to control is complete, you need to use the Keyfactor Command Management Portal to approve the orchestrator (if you don't have auto-registration for Keyfactor Bash Orchestrators enabled) and configure SSH server groups and servers as per Server Manager on page 513 in the *Keyfactor Command Reference Guide*. SSH server records are not automatically created for remote targets, even if you enable auto-registration for bash orchestrators and use the -i switch when registering the bash orchestrator that will control your targets.

5.4.4 Optional Configuration

Once the installation is complete, the Keyfactor Bash Orchestrator should be running and ready to communicate with the Keyfactor Command server. The initial installation allows the orchestrator to scan itself to do discovery of SSH keys and then management of SSH keys if the server is configured for management in Keyfactor Command. At

this point, you may wish to configure one or more orchestrator target servers for the orchestrator to additionally control (see Install Remote Control Targets on page 2441).

Important: Orchestrator tasks will not run until you complete the orchestrator configuration by making the appropriate configuration changes in the Keyfactor Command Management Portal. See Orchestrators on page 444 in the *Keyfactor Command Reference Guide* for instructions on approving the orchestrator in the Keyfactor Command Management Portal on the *Orchestrators->Management* pages and on configuring SSH server groups and servers on the *SSH->Server Managers* page (see Server Manager on page 513 in the *Keyfactor Command Reference Guide*).

5.4.4.1 Configure Logging for the Keyfactor Bash Orchestrator

By default, the Keyfactor Bash Orchestrator places its log files in the /opt/keyfactor-bash-orchestrator/logs directory, generates logs at non-debug level, rotates the logs when they reach 50 MB, and retains 10 archive logs before deletion.

If you wish to change these defaults after the installation is complete:

1. On the orchestrator machine where you wish to adjust logging, open a command shell and change to the directory in which the orchestrator is installed. By default this is /opt/keyfactor-bash-orchestrator.

2. In the command shell in the directory in which the orchestrator is installed, change to the Configuration directory.

3. Using a text editor, open the orchestrator_config file in the Configuration directory. Your orchestrator_config file may have a slightly different layout than shown here, but it will contain the three fields highlighted in the below figure. The fields you may wish to edit are:

    - logFile=/opt/keyfactor-bash-orchestrator/logs/bash-orchestrator-log.txt

      The path and file name of the active orchestrator log file.

      Important: If you choose to change the path for storage of the log files, you will need to create the new directory (e.g. /opt/sshorchlogs) and grant the Linux service account under which the orchestrator service is running (see Create a Service Account for the Keyfactor Bash Orchestrator on page 2435) full control permissions on this directory.

    - logFileSize=50000000
      The maximum file size of each log file. After a log file reaches the maximum size, it is rotated to an archive file name and a new log file is generated. The default is 50000000 (50 MB).
    - logFilesToKeep=10
      The number of archive files to retain before deletion.
    - debugLogEnabled=false
      The level of log detail that should be generated. The default of *false* logs error and some informational data but at a minimal level to avoid generating large log files. For troubleshooting, it may be desirable to set the debug level to *true*.

```
logFile=/opt/keyfactor-bash-orchestrator/logs/bash-orchestrator-log.txt
logFileSize=50000000
logFilesToKeep=10
keyfactorAgentServer=https://keyfactor.keyexample.com/KeyfactorAgents
serverGroupId=71804a75-78de-42fb-bb7e-96b123742f0d
debugLogEnabled=false
clientMachineName=appsrvr79.keyexample.com
```

Figure 550: Configure Logging for the Keyfactor Bash Orchestrator

Tip: Log messages for remote control targets are written to the standard Linux syslog. The location of these will vary depending on the system OS. Log messages for the orchestrator's communication with the remote control targets are included in the primary orchestrator log (described above). It can be helpful to look in both places when troubleshooting an issue with a remote control target.

5.4.4.2 Start the Keyfactor Bash Orchestrator Service

The keyfactor-bash-orchestrator service runs on the Keyfactor Bash Orchestrator machine and controls SSH public key discovery and management tasks for the orchestrator machine itself and target servers it controls. The service should start automatically at the conclusion of the installation.

The service on Linux is added as keyfactor-bash-orchestrator, so when referencing it in startup commands, it should be referenced by this name, including case. For example:

```
systemctl start [stop] [restart] [status] keyfactor-bash-orchestrator.service
```

Once you have finished the SSH server group and server configuration using the Keyfactor Command Management Portal and have completed a scan of the configured servers, you can view discovered keys and logons in the Keyfactor Command Management Portal and then begin using the management features. See SSH on page 479 in the *Keyfactor Command Reference Guide* for information on using the SSH features.

5.5 Troubleshooting

The following error conditions and general troubleshooting tips may be helpful in resolving issues with the Keyfactor orchestrators. Generally speaking, issues are often related to trusts of root and intermediate certificates, firewall challenges, or insufficient permissions for the service account running the orchestrator service.

Validate Management Portal Configuration

Things to check in the Management Portal include:

- Is the last seen time for the orchestrator on the Orchestrator Management page in the Management Portal within the last few minutes (see Orchestrator Management on page 454 in the *Keyfactor Command Reference Guide*)? Most orchestrators send a heartbeat to Keyfactor Command every 5 minutes, so this date should at most be 5 minutes out of date if the orchestrator is operating correctly.

Tip: Orchestrator control targets for the Keyfactor Bash Orchestrator do not appear on the Orchestrator Management page, so for a remote server that's not operating as expected, this would be the orchestrator that is controlling the target.

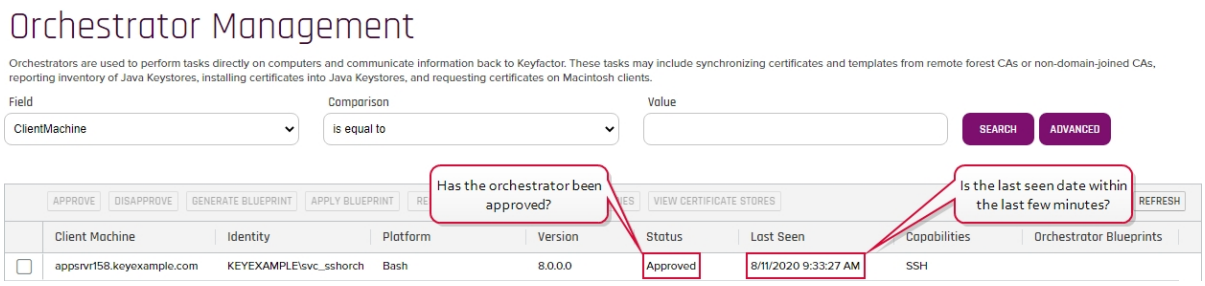

Figure 551: Orchestrator Management for a Keyfactor Bash Orchestrator

- Has the orchestrator been approved on the Orchestrator Management page in the Management Portal (see Orchestrator Management on page 454 in the *Keyfactor Command Reference Guide*)?
- Is there a sync schedule set to run frequently for the orchestrator (SSH), remote control target (SSH), or certificate store? Sync schedules for certificates stores are automatically disabled if inventory jobs are failing.
- For the Keyfactor Bash Orchestrator:
  - Has the server record for the orchestrator or remote control target been created under SSH Server Manager on the Servers tab in the Management Portal (see SSH Servers on page 529 in the *Keyfactor Command Reference Guide*)?

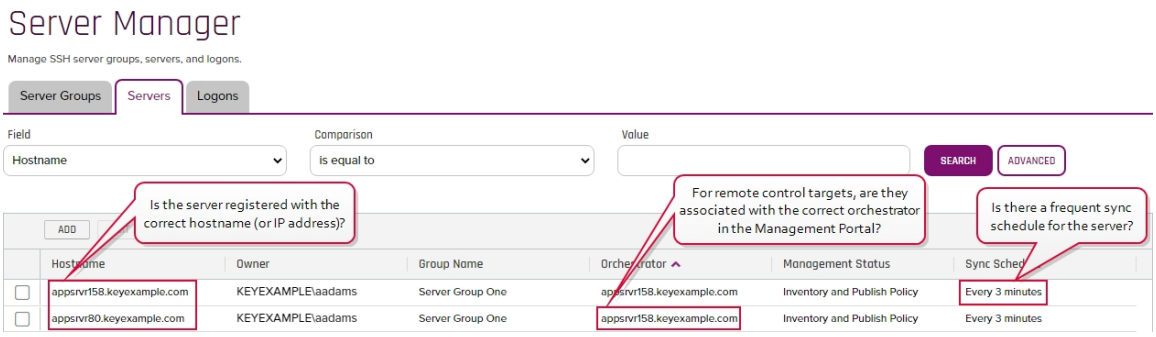

Figure 552: Orchestrator Management for a Keyfactor Bash Orchestrator

  - Does the server record for the orchestrator or remote control target in the Management Portal have the correct hostname or IP address? If the name or IP address is incorrect, sync jobs will fail.
  - Is the server record for the remote control target in the Management Portal associated with the correct orchestrator? If the control target is associated with the wrong orchestrator, you may be looking at the wrong log files (see Debug Logging and Error Messages below) for troubleshooting information.

Debug Logging and Error Messages

It is often helpful to enable debug logging on the orchestrator. For information on configuring this, see the specific orchestrator chapters.

Once the logging is set at debug or trace level, it can be helpful to watch the logs live while activity is going on. On Linux, you can do this with *tail* (or a similar tool) to watch the log in real time. For example:

```
tail -f /opt/keyfactor-bash-orchestrator/logs/keyfactorbash-orchestrator-log.txt
tail -f /opt/keyfactor/orchestrator/logs/Log.txt
```

On Windows, there are also tools with tail-like functionality. Notepad++, for example, has this functionality built in.

Some messages in the KeyfactorUniversal Orchestrator log include a correlation ID that helps to identify log messages that originated from the same request. The correlation ID is a randomly generated GUID that often appears just after the date in the log entry (3E4B7183-12E6-4DAA-955C-FA25080ED995 in the following example) and is the same for all log messages for the given request until the request completes.

```
2022-09-12 10:56:16.4421   Keyfactor.Orchestrators.JobEngine.JobRegistrationService [Trace] -

2022-09-12 11:00:00.0280 3E4B7183-12E6-4DAA-955C-FA25080ED995  Keyfactor.Orches-
trators.JobExecutors.OrchestratorJobExecutor [Info] - Starting FTPInventory for job id 3e4b7183-12e6-
4daa-955c-fa25080ed995
2022-09-12 11:00:01.7554 3E4B7183-12E6-4DAA-955C-FA25080ED995 166942 Keyfactor.Orches-
trators.FTP.FTPUtilities [Debug] - Attempting to download PEM at ftp://ft-
p93.keyexample.com//MyFile.cer
2022-09-12 11:00:01.7554 3E4B7183-12E6-4DAA-955C-FA25080ED995 166942
Keyfactor.Orchestrators.FTP.FTPUtilities [Debug] - Building FTP request
2022-09-12 11:00:01.8059 3E4B7183-12E6-4DAA-955C-FA25080ED995 166942 Keyfactor.Orches-
trators.FTP.FTPUtilities [Error] - Encountered a problem trying to download part of Current PEM or
came across a non PEM file  : The specified network password is not correct.
```

Some messages to look for include:

- This message (or similar—text varies slight from orchestrator to orchestrator) indicates that the orchestrator has not yet been approved in the Keyfactor Command Management Portal:

  ```
  2021-07-29 09:01:28.5957 Keyfactor.Orchestrators.JobEngine.SessionJobExecutor [Info] - Agent has
  not yet been registered with CMS. Trying again in 30 minutes.
  ```

  After approving the orchestrator in the Management Portal, you can restart the orchestrator service to avoid waiting 30 minutes for the next automated retry.
- Some log message spell out the problem pretty clearly. For example, this message from the Java Agent log:

```
2021-07-29 09:00:02.437 [Scheduler_Worker-1] ERROR com.css_security.cms.JksUtilities - Keystore
/opt/apps/myapp.jks loaded as type JKS but the provided password is incorrect
```

In this case, the certificate store configuration in the Management Portal is not using the correct password for the store.

- This series of messages in the Java Agent log indicates that the stored credentials file for the Java Agent is no longer useable:

```
2021-07-01 11:24:59.292 [Scheduler_Worker-1] ERROR com.css_secur-
ity.cms.apache.http.HttpClientFactory - Given final block not properly padded. Such issues can
arise if a bad key is used during decryption.
2021-07-01 11:24:59.313 [Scheduler_Worker-1] ERROR com.css_secur-
ity.cms.apache.http.HttpClientFactory - Could not decrypt credentials file at config/in-
stall.creds
2021-07-01 11:24:59.313 [Scheduler_Worker-1] INFO  com.css_
security.cms.apache.http.HttpClientFactory - Your machine key may have changed. Reencrypt creden-
tials using local machine key.
2021-07-01 11:24:59.313 [Scheduler_Worker-1] INFO  com.css_secur-
ity.cms.apache.http.HttpClientFactory - Generate new credentials by running included cms-creden-
tial-encryptor utility
2021-07-01 11:24:59.313 [Scheduler_Worker-1] INFO  com.css_secur-
ity.cms.apache.http.HttpClientFactory - Try 1. Trying again in 30 seconds
```

The credentials file can be recreated to return the Java Agent to functionality (see Appendix - Generate New Credentials for the Java Agent on page 2460).

- This series of messages indicates that the Keyfactor Command server is unreachable:

```
2021-07-29 11:59:02.1003 Keyfactor.Orchestrators.JobEngine.SessionClient [Error] - Unable to
heartbeat:
2021-07-29 11:59:02.1003 Keyfactor.Orchestrators.JobEngine.SessionClient [Trace] - Leaving CMSSes-
sionClient.Heartbeat
2021-07-29 11:59:02.1006 Keyfactor.Orchestrators.JobEngine.SessionJobExecutor [Debug] - Heartbeat
success: Unreachable
2021-07-29 11:59:02.1006 Keyfactor.Orchestrators.JobEngine.SessionJobExecutor [Warn] - Heartbeat
endpoint unreachable. Trying again later
```

This could indicate a network or firewall issue.

- A series of messages similar to this for the Universal Orchestrator can indicate a problem retrieving the CRL for the certificate used to secure the Keyfactor Command server if you've chosen to connect to Keyfactor Command over SSL:

```
2022-09-14 11:15:06.1830   Keyfactor.Orchestrators.JobEngine.SessionJobExecutor [Error] - Error
in SessionManager: Unable to register session.
The SSL connection could not be established, see inner exception.
The remote certificate is invalid because of errors in the certificate chain: Revoc-
ationStatusUnknown, OfflineRevocation
```

Confirm that the CRLs for the CA that issued the certificate and the remaining CAs in the chain are valid. Confirm that they are available in a location that is accessible to the orchestrator server (e.g. a location other than LDAP if the orchestrator is installed on a server not joined to a domain in the forest where they were issued). If you're using delta CRLs and hosting them on an IIS website using the default CRL suffix as a naming convention (+), be sure to enable double escaping in IIS to allow the orchestrator to retrieve the CRL files containing a plus in the file name.

- Messages that look like errors during SSL scanning are common as attempts are made to connect to TLS endpoints and connections fail or are refused. This is part of the process of testing whether an SSL endpoint is responding and then whether there is a certificate there. Most of these message exist at *Trace* level, so monitoring at *Debug* rather than *Trace* level will eliminate these messages if they become overwhelming. For example:

```
2022-09-12 10:56:32.3948 EE033BD9-421A-44CA-89BC-10C86949B506 166937 Tls13Probe [Trace] -

ets.SocketException': An existing connection was forcibly closed by the remote host.
2022-09-12 10:57:23.4727 EE033BD9-421A-44CA-89BC-10C86949B506 166937 Tls13Probe [Trace] - Connec-
tion to 192.168.216.87:443 failed
2022-09-12 10:57:24.3345 EE033BD9-421A-44CA-89BC-10C86949B506 166937 a [Trace] - Endpoint
192.168.216.211:443 returned status 'ExceptionDownloading' with exception 'Keyfactor.Orches-
trators.SSL.Pipeline.Exceptions.ConnectionGoneException': Read zero bytes on a blocking read
2022-09-12 10:57:57.9505 EE033BD9-421A-44CA-89BC-10C86949B506 166937 b [Trace] - Endpoint
192.168.216.96:443 returned status 'SslRefused' with exception 'Keyfactor.Orches-
trators.SSL.Pipeline.Exceptions.TlsAlertException': Got TLS alert during TLS handshake: Alert
level 2, Alert description 70
```

Heartbeat

You should see a heartbeat message similar to the following in the log every 5 minutes:

- Keyfactor Universal Orchestrator on Windows:

```
2022-09-12 11:01:16.4598   Keyfactor.Orchestrators.JobEngine.SessionJobExecutor [Debug] -
Existing session found. Heartbeating...
```

- Keyfactor Bash Orchestrator:

```
Tue Aug 11 18:06:02 UTC 2021 [Debug]: Performing orchestrator heartbeat...
```

- Keyfactor Java Agent on Linux:

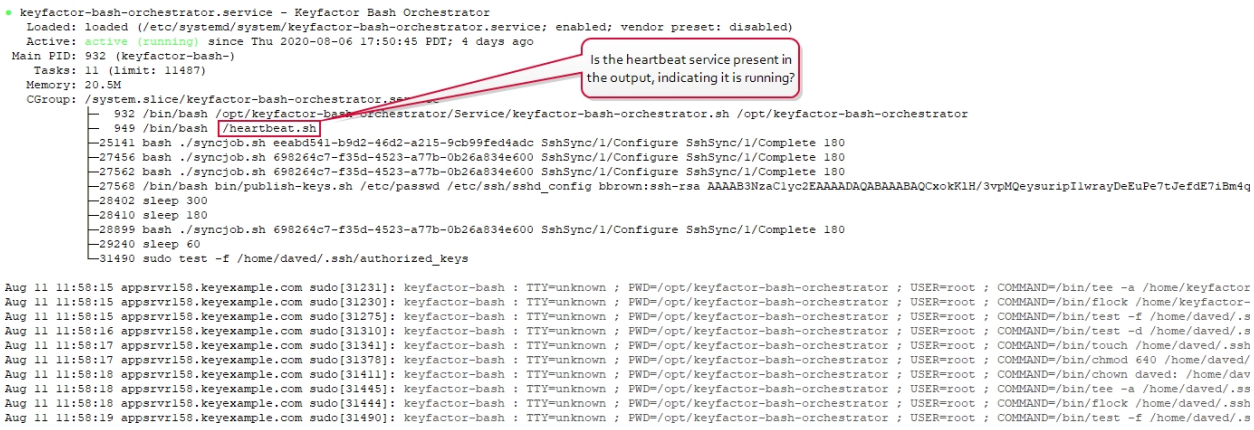
```
2021-07-30 00:52:11.662 [Scheduler_Worker-1] DEBUG com.css_secur-
ity.cms.agents.jobs.SessionManager - Existing session found. Heartbeating...
```

This is the orchestrator checking in with the Keyfactor Command server to see if there are any jobs. If this message is missing, it could indicate that the heartbeat service is not running.

If you're running the Keyfactor Bash Orchestrator, you can see the heartbeat service as a separate entity. Execute this command on the orchestrator in the command shell as root:

```
systemctl status keyfactor-bash-orchestrator.service
```

Output from this command should look something like that shown in Figure 553: Status for the Keyfactor Bash Orchestrator Service. If you don't see heartbeat.sh in the output, the heartbeat service is not running.



```

Figure 553: Status for the Keyfactor Bash Orchestrator Service

For other orchestrators, check to see if the orchestrator service as a whole is running (see details in the specific orchestrator chapters). Start the service if it is not running or restart it if it is running and check again for a heartbeat after a few minutes.

Firewall Ports

At a very basic level, the orchestrator needs to be able to communicate with the Keyfactor Command server(s) on either port 80 or port 443 (depending on the configuration option you've chosen for this connection—see orchestrator specific chapters).

The ports needed for the Keyfactor Universal Orchestrator depend on the functions enabled for the orchestrator. For example, IIS certificate store management uses remote PowerShell (default TCP 5985 and 5986). For SSL discovery and management, any ports configured for scanning need to be open.

The Keyfactor Bash Orchestrator communicates with any remote control targets on port 22 or the alternative port you have configured for SSH. If you are using a non-standard port for SSH, you need to be sure to configure this on both the Keyfactor Command side (see Adding SSH Servers on page 530 in the *Keyfactor Command Reference Guide*) and in the SSH configuration on the orchestrator and remote control targets (sshd_config).

For more information about the firewall ports needed in a Keyfactor Command environment, see Firewall Considerations on page 2237 in the *Keyfactor Command Server Installation Guide*.

Keyfactor Bash Orchestrator Troubleshooting Tips

The Keyfactor Bash Orchestrator has two possible configurations—local and remote. The troubleshooting steps differ depending on whether the server that's not operating as expected is running the orchestrator software (a local installation) or is a control target for the orchestrator (a remote installation). In either case, the best place to start with troubleshooting is in the Keyfactor Command Management Portal to confirm things seem correct on this side of the communication and then configure debug logging on the orchestrator and review those logs.

Successful Inventory and Policy Publishing

In this snippet you see a successful inventory showing keys found for the Linux users ginag and svc_greenchicken and a logon found for the Linux user zadams with no key found. You see that the server is configured in *inventory and publish policy mode*, since after performing the inventory the server went through the steps of publishing logons and keys. Details about these are not written to the log.

```

Validate Service Account Logon

During installation of the orchestrator, a local Linux user account should be created automatically as an identity under which the orchestrator service will operate. This allows the orchestrator to run as a non-root user. On servers on which you install the orchestrator directly, the following Linux user account is created:

keyfactor-bash

On servers configured as remote control targets, the following Linux user account is created:

keyfactor-bash-orchestrator-svc

You can validate that the user has been created and has the correct configuration be reviewing the /etc/passwd file.

In a command shell, output the content of the /etc/passwd file to the screen:

```
cat /etc/passwd
```

In the output from this command, look for the entry for the keyfactor-bash or keyfactor-bash-orchestrator-svc user. It will look similar to one of these:

```
keyfactor-bash:x:978:976::/home/keyfactor-bash:/bin/bash
keyfactor-bash-orchestrator-svc:x:112:65534::/opt/keyfactor-bash-orchestrator-
client:/bin/bash
```

On the remote control target server, you should find an entry in the sshd_config file that directs the service account logon over to the install path for the client to find the authorized_keys file for the service account user, like so:

```
Match User keyfactor-bash-orchestrator-svc
AuthorizedKeysFile    /opt/keyfactor-bash-orchestrator-client/authorized_keys
```

On both the orchestrator and remote control target servers, you should find a file in the /etc/sudoer.d directory named for the service name of the orchestrator or remote control target user (keyfactor-bash or keyfactor-bash-orchestrator-svc) and containing a list of commands the orchestrator is allowed to execute as root. For example:

```
keyfactor-bash appsrvr79.keyexample.com = (root) NOPASSWD: /bin/ls
keyfactor-bash appsrvr79.keyexample.com = (root) NOPASSWD: /bin/cat
keyfactor-bash appsrvr79.keyexample.com = (root) NOPASSWD: /usr/bin/test
keyfactor-bash appsrvr79.keyexample.com = (root) NOPASSWD: /bin/rm
keyfactor-bash appsrvr79.keyexample.com = (root) NOPASSWD: /usr/bin/tee
keyfactor-bash appsrvr79.keyexample.com = (root) NOPASSWD: /bin/touch
keyfactor-bash appsrvr79.keyexample.com = (root) NOPASSWD: /bin/chmod
keyfactor-bash appsrvr79.keyexample.com = (root) NOPASSWD: /bin/chown
keyfactor-bash appsrvr79.keyexample.com = (root) NOPASSWD: /usr/bin/gpasswd
keyfactor-bash appsrvr79.keyexample.com = (root) NOPASSWD: /usr/sbin/usermod
keyfactor-bash appsrvr79.keyexample.com = (root) NOPASSWD: /bin/sed
keyfactor-bash appsrvr79.keyexample.com = (root) NOPASSWD: /usr/bin/flock
keyfactor-bash appsrvr79.keyexample.com = (root) NOPASSWD: /bin/mkdir
keyfactor-bash appsrvr79.keyexample.com = (root) NOPASSWD: /usr/sbin/adduser
```

Validate Remote Control Target Public Key

The orchestrator connects to the remote control targets it is managing using SSH with a public key pair. On the orchestrator, the key pair is stored in the .ssh directory under the directory where the orchestrator is installed. By default, this is:

```
/opt/keyfactor-bash-orchestrator/.ssh
```

Both the private key (id_rsa) and public key (id_rsa.pub) are found here.

In a command shell, output the content of the public key file to the screen:

```
cat id_rsa.pub
```

On the remote control target, the public key of the key pair is stored in the authorized_keys file for the remote control target service account, which is found in the remote control install path. By default, this is:

```
/opt/keyfactor-bach-orchestrator-client
```

In a command shell, output the content of the authorized_keys file to the screen:

```
cat authorized_keys
```

Compare the public key string from the remote control target authorized_keys file to the public key string from the orchestrator id_rsa.pub file. They should match exactly. If they do not match, the remote control target is not using the correct public key, which will cause connection attempts made to it from the orchestrator to fail.

Tip: You should also see in the .ssh directory on the orchestrator a file named by hostname (e.g. appsr-vr80.keyexample.com) for each of the remote control targets managed by the orchestrator. These contain a list of known, trusted host key stores. If this file has not be created for your remote control target, connectivity to the target is failing at a very fundamental level (before the stage of a public key mismatch). See Firewall Ports on page 2449.

Keyfactor Bash Orchestrator Log Messages

If the orchestrator is managing more than one server (remote control targets), it can be difficult to interpret the logs, because the orchestrator operates in a multi-threaded manner and log messages for jobs with different servers will be mixed together. Find a message related to the job you're interested in and look for the ID for that job. Then look for all other messages referencing that ID.

Look for error messages in the log. These should appear with the word *Error* in brackets just after the date like so:

```
Tue Aug 11 19:14:33 UTC 2020 [Error]: Error occurred during job with id 'b835bde8-8174-447a-b351-
810e582148c0' on server 'appsrvr79.keyexample.com': An error occurred attempting to configure the
job 'b835bde8-8174-447a-b351-810e582148c0'
```

This particular message doesn't tell you very much except that this job was unable to complete for some reason. If you look at the debug messages that appear immediately before and after the error message, they may provide more information.

This message indicates that the orchestrator was unable to make an SSH connection to the remote control target named in the message:

```
Mon Aug 10 23:36:10 UTC 2020 [Error]: Error occurred during job with id '3f04f552-05fd-4c90-b3b1-
edeec70878bb' on server 'appsrvr80.ubuntu.keyexample.com': Unable to connect to 'appsr-
vr80.ubuntu.keyexample.com' on port '22' via SSH
```

This could happen for a number of reasons. Perhaps the hostname configured for the remote target is incorrect. Perhaps the public key on the remote target is incorrect. It can be helpful in this case to check the Linux syslog on the orchestrator for more context on the message. For example, this set of messages from the Linux syslog reveals that the public key on the target is invalid in some fashion:

```
Aug 11 13:03:04 appsrvr158 keyfactor-bash[29417]: Testing 'keyfactor-bash-orchestrator-svc' on
server 'appsrvr80.keyexample.com' via SSH for job with id 'eeabd541-b9d2-46d2-a215-9cb99fed4adc'...
Aug 11 13:03:04 appsrvr158 keyfactor-bash-orchestrator.sh[932]: keyfactor-bash-orchestrator-
```

```
svc@appsrvr80.keyexample.com: Permission denied (publickey).
Aug 11 13:03:30 appsrvr158 keyfactor-bash[29486]: Error occurred during job with id 'eeabd541-b9d2-
46d2-a215-9cb99fed4adc' on server 'appsrvr80.keyexample.com': Unable to connect to 'appsr-
vr80.keyexample.com' on port '22' via SSH
```

For information on troubleshooting public key issues with remote control targets, see Validate Remote Control Target Public Key on page 2452. For more information on troubleshooting remote control target issues in general, see Remote Control Target Logs below. For information on what successful inventory and publish policy log messages look like, see Successful Inventory and Policy Publishing on page 2450.

Remote Control Target Logs

Unlike on the orchestrator itself, where you can enable debug logging to see a more detailed picture of what's going on when the orchestrator attempt to connect or run a job, on a remote control target, the only logs available are the SSH logs showing attempts by the orchestrator to make a remote connection into the target and then the commands the orchestrator runs from an SSH perspective. These logs are found in the Linux system log where SSH logs are consolidated. The name and location of this will vary by operating system, but it is often found in /var/log by default (*auth.log* or *secure* is common). A large number of entries are generated in the log on a successful connection for inventory or inventory and policy publishing, so it can be difficult to interpret the logs.

In these logs you can check to see if the orchestrator is successfully making an SSH connection. If it isn't, you may see some messages that will help determine why it isn't. If it's successfully making the initial connection but then failing further along in the process, this log may also help reveal that. Perhaps one of the commands that the service account needs to run isn't in the expected path, for example.

When the orchestrator first connects to the remote control target, the log entries on the target will look something like:

```
Aug 11 17:36:51 appsrvr80 sshd[95543]: Accepted publickey for keyfactor-bash-orchestrator-svc from
10.4.3.158 port 47778 ssh2: RSA SHA256:u5zNB4UEoPNcax5p4fBbkkWaoiWq6AcEkA65XdzUkM4
Aug 11 17:36:51 appsrvr80 sshd[95543]: pam_unix(sshd:session): session opened for user keyfactor-
bash-orchestrator-svc by (uid=0)
Aug 11 17:36:51 appsrvr80 systemd-logind[656]: New session 13019 of user keyfactor-bash-orches-
trator-svc.
Aug 11 17:36:51 appsrvr80 systemd: pam_unix(systemd-user:session): session opened for user
keyfactor-bash-orchestrator-svc by (uid=0)
Aug 11 17:36:51 appsrvr80 sudo: keyfactor-bash-orchestrator-svc : TTY=unknown ; PWD=/opt/keyfactor-
bash-orchestrator-client ; USER=root ; COMMAND=/bin/cat /etc/ssh/sshd_config
```

An inventory of an authorized_keys file for a user will appear as a series of entries, something like:

```
Aug 11 18:11:28 appsrvr164 sudo: keyfactor-bash-orchestrator-svc : TTY=unknown ; PWD=-
=/opt/keyfactor-bash-orchestrator-client ; USER=root ; COMMAND=/bin/test -f /home/j-
smith/.ssh/authorized_keys
Aug 11 18:11:28 appsrvr164 sudo: keyfactor-bash-orchestrator-svc : TTY=unknown ; PWD=-
=/opt/keyfactor-bash-orchestrator-client ; USER=root ; COMMAND=/bin/ls -l /home/j-
smith/.ssh/authorized_keys
Aug 11 18:11:28 appsrvr164 sudo: keyfactor-bash-orchestrator-svc : TTY=unknown ; PWD=-
=/opt/keyfactor-bash-orchestrator-client ; USER=root ; COMMAND=/bin/cat /home/j-
smith/.ssh/authorized_keys
```

Removal of a rogue key on a remote control target under management (in *inventory and publish policy* mode) will appear as a series of entries where the authorized_keys file is removed, recreated and repopulated with any valid keys (none in this case), like:

```
Aug 12 09:01:24 appsrvr80 sudo: keyfactor-bash-orchestrator-svc : TTY=unknown ; PWD=/opt/keyfactor-
bash-orchestrator-client ; USER=root ; COMMAND=/usr/bin/test -f /home/jsmith/.ssh/authorized_keys
Aug 12 09:01:24 appsrvr80 sudo: keyfactor-bash-orchestrator-svc : TTY=unknown ; PWD=/opt/keyfactor-
bash-orchestrator-client ; USER=root ; COMMAND=/bin/rm /home/jsmith/.ssh/authorized_keys
Aug 12 09:01:25 appsrvr80 sudo: keyfactor-bash-orchestrator-svc : TTY=unknown ; PWD=/opt/keyfactor-
bash-orchestrator-client ; USER=root ; COMMAND=/usr/bin/test -f /home/jsmith/.ssh/authorized_keys
Aug 12 09:01:25 appsrvr80 sudo: keyfactor-bash-orchestrator-svc : TTY=unknown ; PWD=/opt/keyfactor-
bash-orchestrator-client ; USER=root ; COMMAND=/usr/bin/test -d /home/jsmith/.ssh
Aug 12 09:01:25 appsrvr80 sudo: keyfactor-bash-orchestrator-svc : TTY=unknown ; PWD=/opt/keyfactor-
bash-orchestrator-client ; USER=root ; COMMAND=/usr/bin/touch /home/jsmith/.ssh/authorized_keys
Aug 12 09:01:25 appsrvr80 sudo: keyfactor-bash-orchestrator-svc : TTY=unknown ; PWD=/opt/keyfactor-
bash-orchestrator-client ; USER=root ; COMMAND=/bin/chmod 640 /home/jsmith/.ssh/authorized_keys
Aug 12 09:01:25 appsrvr80 sudo: keyfactor-bash-orchestrator-svc : TTY=unknown ; PWD=/opt/keyfactor-
bash-orchestrator-client ; USER=root ; COMMAND=/bin/chown jsmith: /home/jsmith/.ssh/authorized_keys
Aug 12 09:01:25 appsrvr80 sudo: keyfactor-bash-orchestrator-svc : TTY=unknown ; PWD=/opt/keyfactor-
bash-orchestrator-client ; USER=root ; COMMAND=/usr/bin/flock /home/jsmith/.ssh/authorized_keys
echo
Aug 12 09:01:25 appsrvr80 sudo: keyfactor-bash-orchestrator-svc : TTY=unknown ; PWD=/opt/keyfactor-
bash-orchestrator-client ; USER=root ; COMMAND=/usr/bin/tee -a /home/jsmith/.ssh/authorized_keys
```

General Errors

Below are some possible errors you might encountered and some suggested troubleshooting tips or solutions.

Permission denied (80131500)

Here is an example of an error you might see when using a certificate store:

```
Error: Site Error attempting to retrieve certificates for store
path=/etc/nginx/ssl/dev.tid.onespan.cloud/chain.pem. Permission denied (80131500)
```

A "permission denied" error of this type is often the result of one of these issues:

- The service account used to authenticate the orchestrator into the target server does not have permissions or access to SFTP on that server (for an FTP certificate store).
- The service account does not have the proper permissions to read or write to the file and/or folder.

To troubleshoot permission denied issues:

1. Open a command prompt and type:

   ```
   sftp username@server IP or hostname
   ```
   or
   ```
   psftp username@server IP or hostname
   ```
   For example:
   ```
   psftp kyfuser@192.168.12.73
   ```

2. COnce connected to the target server, confirm that you can access the folder and files. For example, use the ls command to list the directory contents and check that the files are there and have correct permissions for your user.

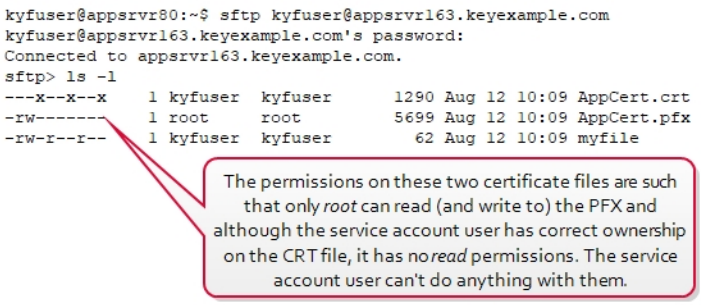

Figure 554: Check File Permissions for the User

3. If the service account user needs access to these files, you will need to change the permissions on them. This cannot be done over FTP/SFTP.

4. To correct the problem with the CRT file, you will need to add read permissions for the service account user, at a minimum. This can be done with the following chmod command:

   ```
   chmod 640 AppCert.crt
   ```
   This command grants the owner of the file (correct in this case) read and write permission on the file (permission level 6 = 4 (read) + 2 (write)), the group associated with the file read permissions (permission level 4), and all others no permissions (permission level 0). No users have execute permissions (permission level 1). A certificate file does not need to be executable.

5. To correct the problem with the PFX file, you need to be acting as root, since only root presently has permissions to the file. You will probably want to change the file ownership to your service account user and then

set the permissions appropriately as follows.

Set the owner on the file with the chown command:

```
sudo chown kyfuser AppCert.pfx
```

Set the group on the file with the chgrp command (notice you don't need to use sudo here because you now have permissions on the file because you own it):

```
chgrp kyfuser AppCert.pfx
```

Set the permissions on the file with the chmod command:

```
chmod 640 AppCert.pfx
```

Unable to connect to the remote server

Here is an example of some very similar errors you might see when trying to connect to a target machine to inventory a certificate store or execute a management or discovery job on a certificate store:

```
Error: Unable to connect to the remote server - No connection could be made because the
target machine actively refused it 192.196.12.12:443 (80131500)
Error: Unable to complete the inventory operation. One or more errors occurred.
An error occurred while sending the request.
Unable to connect to the remote server
A connection attempt failed because the connected party did not properly respond after a
period of time, or established connection failed because connected host has failed to
respond 192.168.12.12:443 (80131500)
Error: Unable to connect to the remote server (80131509)
Error occurred during job with id 'b5e93ae6-df3b-4b36-9640-b41146db6d36' on server
'appsrvr13.keyexample.com': Unable to connect to 'appsrvr13.keyexample.com' on port '22'
via SSH
```

Messages of this type are generally the result of the target server being inaccessible. This might happen if the server was turned off or in maintenance mode. Perhaps there is a network problem routing to that server. If the certificate store has never worked in Keyfactor Command, perhaps there is a typo in the server name configuration.

Request Entity Too Large

You may encounter this error when doing an inventory of an IIS certificate store:

```
Error: Response status code does not indicate success: 413 (Request Entity Too Large).
(80131500)
```

This is an indication that the certificate store you are inventorying contains more certificates (or more precisely, the certificates add up to a total number of bytes greater) than IIS on the Keyfactor Command server is configured to accept. To resolve this, adjust the values on the IIS server that control the upload limits. For example, the *maxAllowedContentLength*. See Monitoring Network Scan Jobs with View Scan Details on page 428 in the *Keyfactor Command Reference Guide*) on fine tuning SSL monitoring for more information.

IIS Error 403.16

You may receive a 403.16 error while trying to authenticate an orchestrator to Keyfactor Command using certificate authentication. On the face of it, this error indicates that the chain for the certificate you're using to authenticate is not trusted by the Keyfactor Command server. First, check to be sure that your certificate is trusted by the Keyfactor Command server. But if your certificate is fully trusted and you're still getting this error, what then?

This error can indicate that the trusted root store on the Keyfactor Command server contains a certificate that is not a root certificate (for example, an intermediate certificate is accidentally in the root store). To check this, open the Local Computer certificates MMC on the Keyfactor Command server, drill down to Certificates under the Trusted Root Certificate Authorities and scan for any certificates where the *Issued To* does not match the *Issued By*. Remove any certificates you find like this.

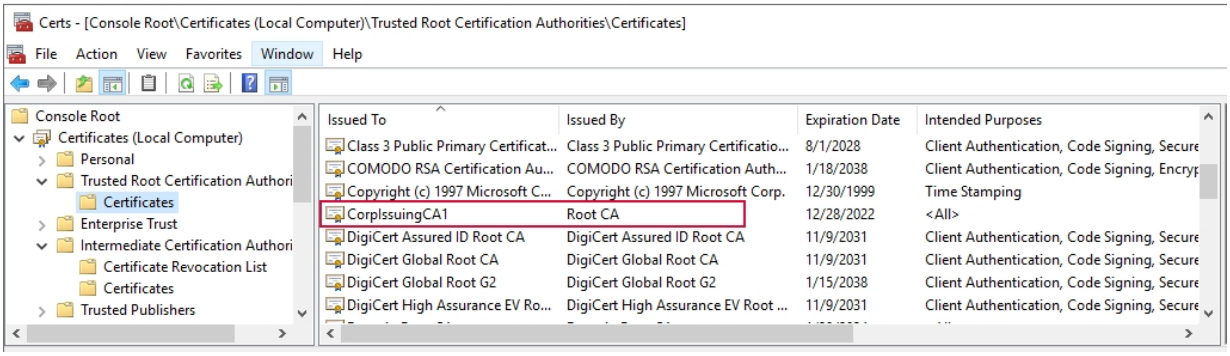

Figure 555: Certificate Incorrectly in the Trusted Root Certificate Store

Error: An attempt was made to load a program with an incorrect format.

If you receive an error similar to the following:

```
Could not load file or assembly 'Keyfactor.CAClient.Microsoft.DCOM, Version=2.1.1.0,
Culture=neutral, PublicKeyToken=0ed89d330114ab09'. An attempt was made to load a program
with an incorrect format.
```

This may indicate that the Keyfactor Universal Orchestrator was installed without the Microsoft Visual C++ Redistributable x64 required to manage certificates from remote Microsoft CAs (see System Requirements on page 2360).

Error: The remote certificate is invalid because of errors in the certificate chain

If you receive an error similar to the following (some portions of message removed for clarity):

```
2023-02-15 11:54:27.6600   Keyfactor.Orchestrators.JobEngine.SessionJobExecutor [Error] - Error in
SessionManager: Unable to register session.

The SSL connection could not be established, see inner exception.
```

```
The remote certificate is invalid because of errors in the certificate chain: Revoc-
ationStatusUnknown, OfflineRevocation
```

This may indicate that the Keyfactor Universal Orchestrator cannot access the CRL(s) for the SSL certificate used to secure the Keyfactor Command server (see System Requirements on page 2360).

To check this:

1. Enable at least debug level logging (see Configure Logging for the Universal Orchestrator on page 2398).
2. Either wait for the orchestrator to attempt to register again, or restart the orchestrator service (see Start the Universal Orchestrator Service on page 2401) to force an immediate attempt to register.
3. Look in the logs for a log message similar to the following (referencing your Keyfactor Command server name):

   ```
   2023-02-15 12:08:14.6076 Keyfactor.Orchestrators.Core.Http.KeyfactorHttpClient
   [Debug] - Sending request to
   'https://keyfactor.keyexample.com/KeyfactorAgents/Session/Register'
   ```

4. Visit the referenced URL (https://keyfactor.keyexample.com/KeyfactorAgents/Session/Register) in a browser on the orchestrator server. This should give you a response of:

   ```
   The requested resource does not support http method 'GET'.
   ```

5. In the browser, view details for the certificate (the exact method for this will vary depending on the browser) and check the *CRL Distribution Points* field in the certificate.

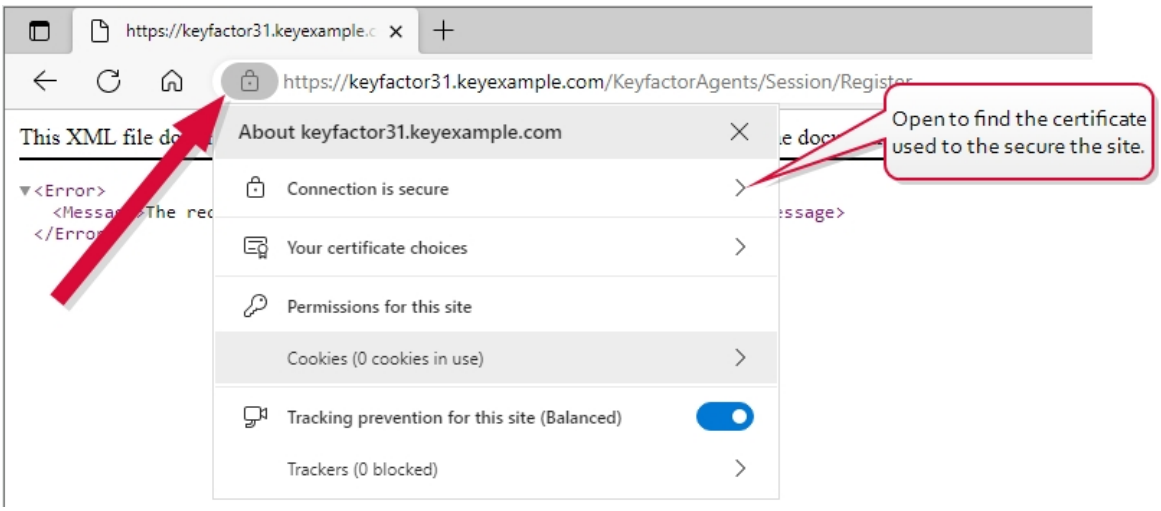

Figure 556: Find the Certificate for the Keyfactor Command Web Site

6. In the same browser on the orchestrator server, attempt to browse to the URL for the CRL (assuming it's a URL).

7. If the CRL downloads without error, then likely CRL access is not the issue. Open the CRL and check the *Next update* date to see if it's in the past (indicating the CRL is out of date).

> **Note:** CRL checks are done on port 80 since the CRL lookup is part of the validation of the server's SSL certificate. This means the CRLs need to be available at an http URL. The CRL file that is retrieved is signed by the CA, so although the network communication is not encrypted when retrieving it, the data that is being validated can't be tampered with (because it is signed).

IIS Helpful Tools

- Test PS Session from the orchestrator server to the IIS server:

```
Enter-PSSEssion -ComputerName <target IIS>
```

5.6 Appendices

- Appendix - Generate New Credentials for the Java Agent below
- Appendix - Set up the Universal Orchestrator to Use Client Certificate Authentication via a Reverse Proxy: Citrix ADC on page 2462
- Appendix - Set up the Universal Orchestrator to Use Client Certificate Authentication with Certificates Stored in Active Directory on page 2474
- Appendix - Set up the Universal Orchestrator to Use a Forwarding Proxy on page 2488

5.6.1 Appendix - Generate New Credentials for the Java Agent

Under some circumstances, you may find it necessary to generate new credentials for the Java Agent. This can happen, for example, if you make a change to the hostname of the machine on which the Java Agent is running. The credentials file stores the username and password for the service account user that allows the Java Agent to communicate with Keyfactor Command—the identity for the agent (see Create Service Accounts for the Java Agent on page 2412)—encrypted with the hostname to prevent the file from being used on machines other than the machine on which the agent has been installed.

Log messages that indicate a new credentials file is needed look similar to the following:

```
2020-10-02 15:21:43.307 [Scheduler_Worker-1] ERROR com.css_security.cms.apache.http.HttpClientFactory
- Given final block not properly padded. Such issues can arise if a bad key is used during decryp-
tion.
2020-10-02 15:21:43.307 [Scheduler_Worker-1] ERROR com.css_security.cms.apache.http.HttpClientFactory
- Could not decrypt credentials file at config\install.creds
2020-10-02 15:21:43.526 [Scheduler_Worker-1] INFO  com.css_security.cms.apache.http.HttpClientFactory
- Your machine key may have changed. Reencrypt credentials using local machine key.
```

```
2020-10-02 15:21:43.541 [Scheduler_Worker-1] INFO  com.css_security.cms.apache.http.HttpClientFactory
- Generate new credentials by running included cms-credential-encryptor utility
```

To generate a new credentials file on Windows:

1. Open a command prompt using the "Run as administrator" option.
2. Change directories to the directory in which the Java Agent is installed. By default, this is:
   C:\Program Files\Keyfactor\Keyfactor Java Agent
3. Type the following command to generate a new credentials file in the current directory:
   `java -jar CSS.CMS.CredentialEncryptor.jar encode-basic install.creds`
4. Locate the existing credentials file in the config directory under the installed directory. By default, this is:
   C:\Program Files\Keyfactor\Keyfactor Java Agent\config
5. Delete or name off the existing install.creds file in the config directory and copy the new install.creds file from the base install directory to the config directory.
6. Restart the Java Agent service (see Start the Keyfactor Java Agent Service on page 2431).
7. Review the log messages to confirm that credential errors are no longer occurring (see Configure Logging for the Java Agent on page 2429).

To generate a new credentials file on Linux:

1. Open a command shell.
2. Change directories to the directory in which the Java Agent is installed. By default, this is:
   /opt/keyfactor-java-agent
3. As a user with rights to write to the current directory (or use sudo), type the following command to generate a new credentials file in the current directory:
   `java -jar CSS.CMS.CredentialEncryptor.jar encode-basic install.creds`
4. Locate the existing credentials file in the config directory under the installed directory. By default, this is:
   /opt/keyfactor-java-agent/config
5. Delete or name off the existing install.creds file in the config directory and copy the new install.creds file from the base install directory to the config directory.
6. Restart the Java Agent service (see Start the Keyfactor Java Agent Service on page 2431).
7. Review the log messages to confirm that credential errors are no longer occurring (see Configure Logging for the Java Agent on page 2429).

5.6.2 Appendix - Set up the Universal Orchestrator to Use Client Certificate Authentication via a Reverse Proxy: Citrix ADC

The Keyfactor Universal Orchestrator can be configured to support TLS termination at a reverse proxy or network edge device such as a Citrix ADC (a.k.a. NetScaler) or F5. The orchestrator supports using either basic authentication or client certificate authentication between the orchestrator and the Keyfactor Command orchestrator endpoint. When a client certificate is used for the segment between the orchestrator and the reverse proxy, the reverse proxy authenticates the orchestrator with the provided client certificate and then sends the certificate on to Keyfactor Command as an added request header to authenticate the orchestrator to Keyfactor Command with the original certificate. The orchestrator is authenticated and authorized to make the connection to Keyfactor Command in one of two ways:

- A username and password with appropriate permissions within Keyfactor Command are stored on the reverse proxy and presented to Keyfactor Command as part of the request. Basic authentication is used to authenticate the reverse proxy to IIS on the Keyfactor Command server. The same credentials provide authorization for the orchestrator in Keyfactor Command. The original certificate from the orchestrator, provided in a request header, authenticates the orchestrator to the Keyfactor Command orchestrator endpoint.
- A username and password with appropriate permissions within Keyfactor Command are stored in IIS on the Keyfactor Command. In this scenario, a second client certificate residing on the reverse proxy is used to authenticate the reverse proxy to IIS on the Keyfactor Command server. The basic authentication credentials provide authorization for the orchestrator in Keyfactor Command and the original client certificate from the request header provides authentication. The basic authentication credentials are stored locally and do not need to travel over the network. The original certificate from the orchestrator, provided in a request header, authenticates the orchestrator to the Keyfactor Command orchestrator endpoint.

The following instructions cover one method of configuring a Citrix ADC device to support these.

> **Tip:** The following provides instructions for using the Citrix ADC GUI interface to create the appropriate configuration. The same configuration could be accomplished using the command line interface.

Complete the following steps and then configure the orchestrator to enable client certificate authentication as per the installation instructions (see --client-auth-certificate on page 2384 or Install the Universal Orchestrator on Windows on page 2372).

Define Rewrite Actions in Citrix

Create the following two rewrite actions.

> **Tip:** If you're using a second client certificate to authenticate the proxy to Keyfactor Command, you only need to create the first of these actions.

Capture the client certificate from the orchestrator:

1. In the Citrix ADC GUI, browse to *AppExpert > Rewrite > Actions*.
2. On the Rewrite Actions page, click **Add**.

3. On the Create Rewrite Action page, enter a **Name** for the action that will take the certificate received from the orchestrator and convert it to PEM format (e.g. CaptureClientCert).

4. Give the action a *Type* of *INSERT_HTTP_HEADER*.

5. Give the action a *Header Name* (e.g. NS-ClientCert). Be sure to make a note of this header name. You will need it later when you configure certificate authentication for the orchestrator.

6. Enter an *Expression* to convert the client authentication certificate to PEM format:
   ```
   CLIENT.SSL.CLIENT_CERT.TO_PEM
   ```

7. Enter *Comments* if desired and click **OK** to save the action.

Store basic authentication credentials to authenticate the proxy to IIS on the Keyfactor Command server and provide authorization information:

1. Click **Add** to add another action.

2. On the Create Rewrite Action page, enter a **Name** for the action that will send the basic authentication credentials for the orchestrator to Keyfactor Command (e.g. SendServiceCreds).

3. Give the action a *Type* of *INSERT_HTTP_HEADER*.

4. Give the action a *Header Name* of *Authorization*.

5. Enter an *Expression* to send Base64-encoded basic authentication credentials to the Keyfactor Command server (where *service@keyexample.com* and *MySecurePassword* are the correct service name and password for your environment):
   ```
   "Basic "+("service@keyexample.com"+":"+"MySecurePassword").B64ENCODEM
   ```

6. Enter *Comments* if desired and click **OK** to save the action.

Define Rewrite Policies in Citrix

Create the following two rewrite policies.

> **Tip:** If you're using a second client certificate to authenticate the proxy to Keyfactor Command, you only need to create the first of these policies.

Put the client certificate from the orchestrator in the header:

1. In the Citrix ADC GUI, browse to *AppExpert > Rewrite > Policies*.

2. On the Rewrite Policies page, click **Add**.

3. On the Create Rewrite Policy page, enter a **Name** for the policy that will confirm that a certificate has been received from the orchestrator and run the action to convert it to PEM format (e.g. NS-GetCert).

4. Give the policy the **Action** you created in the previous section to capture the client authentication certificate (e.g. CaptureClientCert).

5. Define a **Log Action** if desired.

6. Set the **Undefined-Result Action** to *-Global-undefined-result-action-*.

7. Enter an *Expression* to validate that the client authentication certificate has been received from the orchestrator:
   ```
   CLIENT.SSL.CLIENT_CERT.EXISTS
   ```

8. Enter *Comments* if desired and click **OK** to save the policy.

Send the basic authentication credentials to the Keyfactor Command server:

1. Click **Add** to add another policy.

2. On the Create Rewrite Policy page, enter a **Name** for the policy that will send the basic authentication credentials for the orchestrator to the Keyfactor Command server (e.g. NS-SendCreds).

3. Give the policy the **Action** you created in the previous section to send the basic authentication credentials (e.g. SendServiceCreds).

4. Define a **Log Action** if desired.

5. Set the **Undefined-Result Action** to *-Global-undefined-result-action-*.

6. Enter an *Expression* to confirm that the authorization header does not already exist in the request header:
   ```
   HTTP.REQ.HEADER("Authorization").EXISTS.NOT
   ```

7. Enter *Comments* if desired and click **OK** to save the policy.

Define a Responder Policy in Citrix

Create the following responder policy.

Validate that the client certificate presented by the orchestrator was issued by the specified issuing CA:

1. In the Citrix ADC GUI, browse to *AppExpert > Responder > Policies*.

2. On the Responder Policies page, click **Add**.

3. On the Create Responder Policy page, enter a **Name** for the policy that will validate that the certificate received from the orchestrator was issued by the correct CA (e.g. NS-ValidateIssuer).

4. Select an **Action** of *Reset*.

5. Define a **Log Action** if desired.

6. Do not configure an **AppFlow Action**.

7. Set the **Undefined-Result Action** to *-Global-undefined-result-action-*.

8. Enter an *Expression* to confirm that the certificate received from the orchestrator was issued from the correct issuing CA (where *CorpIssuingCA* is the logical name of your CA):
   ```
   CLIENT.SSL.CLIENT_CERT.ISSUER.CONTAINS("CorpIssuingCA").NOT
   ```

Tip: Connections from the orchestrator will fail if the client authentication certificate was issued by any CA other than the one configured here. You can use AND logic to add more than one CA. For example:

```
CLIENT.SSL.CLIENT_CERT.ISSUER.CONTAINS("CorpIssuingCA1").NOT &&
CLIENT.SSL.CLIENT_CERT.ISSUER.CONTAINS("CorpIssuingCA2").NOT
```

With this expression, certificates issued from either one of these CAs would be accepted.

9. Enter *Comments* if desired and click **OK** to save the policy.

Update the Virtual Server in Citrix

Important: Once you modify the virtual server to require certificates for authentication, many other Keyfactor Command transactions will no longer function if they are sharing the same virtual server. Be sure that you are using a separate virtual server for incoming requests to /KeyfactorAgents on the Keyfactor Command server versus other types of requests. The following instructions refer to setting all policies on a single load balancing virtual server, but your configuration may include multiple virtual servers of other types, which may require slight modifications to these instructions.

Modify the configuration for your load balancing virtual server that is used for Keyfactor Command KeyfactorAgent requests as follows.

Configure the Citrix device to authenticate the orchestrator using its client certificate:

1. In the Citrix ADC GUI, browse to *Traffic Management > Load Balancing > Virtual Servers*.
2. On the Virtual Servers page, select your virtual server and click **Edit**.
3. In the SSL Parameters section, click to edit, check the **Client Authentication** box, and set the **Client Certificate** dropdown to **Mandatory**.

Associate the two rewrite policies.

Tip: If you're using a second client certificate to authenticate the proxy to Keyfactor Command, you only need to associate the first of these policies.

Configure the policy to include the certificate in the header:

1. On the Virtual Servers page, under Advanced Settings expand Policies.
2. In the Policies section, click the plus to add a new policy.
3. On the Choose Type page, select **Choose Policy***Rewrite* and **Choose Type***Request* and click **Continue**.
4. On the Choose Type page, click **Add Binding**.
5. On the Policy Binding page, click the **Select Policy** field and on the Rewrite Policies page select the radio button for the rewrite policy you created to capture the client authentication certificate (e.g. NS-GetCert). Click **Select** to save the selection.

6. On the Policy Binding page, set a **Priority** of 110.
7. Set **Goto Expression** to *Next*.
8. Set **Invoke LabelType** to *None*.
9. Click **Bind** to save the binding.

Configure the policy to send the basic authentication credentials to the Keyfactor Command server:

1. On the Choose Type page for Rewrite Request, click **Add Binding**.
2. On the Policy Binding page, click the **Select Policy** field and on the Rewrite Policies page select the radio button for the rewrite policy you created to send the service account credentials to the Keyfactor Command server (e.g. NS-SendCreds). Click **Select** to save the selection.
3. On the Policy Binding page, set a **Priority** of 120.
4. Set **Goto Expression** to *Next*.
5. Set **Invoke LabelType** to *None*.
6. Click **Bind** to save the binding.
7. Click **Close** to return to the virtual server settings page.

Associate the responder policy:

1. On the Virtual Servers page, in the Policies section, click the plus to add a new policy.
2. On the Choose Type page, select **Choose Policy** *Responder* and **Choose Type** *Request* and click **Continue**.
3. On the Choose Type page, click **Add Binding**.
4. On the Policy Binding page, click the **Select Policy** field and on the Responder Policies page select the radio button for the responder policy you created to validate the issuer of the client authentication certificate (e.g. NS-ValidateIssuer). Click **Select** to save the selection.
5. On the Policy Binding page, set a **Priority** of 100.
6. Set **Goto Expression** to *END*.
7. Set **Invoke LabelType** to *None*.
8. Click **Bind** to save the binding.
9. Click **Close** to return to the virtual server settings page.

Configure Keyfactor Command for Client Certificate Authentication

Once you have all the components configured on Citrix, you're ready to configure Keyfactor Command to enable client certificate authentication for the orchestrators. Once you do this, all orchestrators connecting to this instance of Keyfactor Command will be required to provide a certificate to authenticate. If you have some

orchestrators deployed that do not support certificate authentication (e.g. Java agents), you will need to design a solution with multiple Keyfactor Command servers to support multiple authentication types. Contact your Keyfactor representative for assistance with this.

To configure Keyfactor Command to require client certificate authentication for orchestrators:

1. On the Keyfactor Command server, open the Keyfactor Configuration Wizard.
2. In the Certificate Authentication section of the Orchestrators tab, check the **Enabled** box.
3. In the **Certificate Authentication HTTP Header** field, enter the *Header Name* you gave to the rewrite action you created to capture the certificate from the orchestrator (e.g. NS-ClientCert). Keyfactor Command uses the certificate supplied in this header to identify the orchestrator attempting to authenticate.
4. In the **Certificate Authentication Username** and **Certificate Authentication Password** fields, enter the credentials for an Active Directory service account for the orchestrator(s).

   Tip: The service account entered here does not need to match the service account entered on the Citrix device to authenticate the orchestrator.

5. Click **Verify Configuration** and **Apply Configuration**.

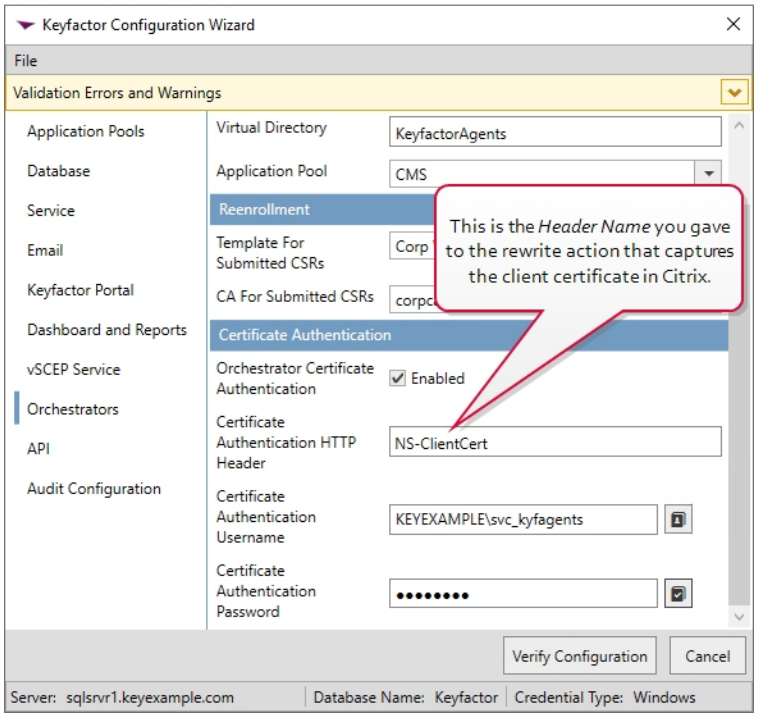

Figure 557: Configure Keyfactor Command for Client Certificate Authentication

Configure IIS to Provide Credentials When a Second Client Certificate is Used to Authenticate the Proxy

If you have opted to configure the Citrix ADC device to use a client certificate to authenticate from the device to the Keyfactor Command server instead of submitting basic authentication credentials from the device, you will need to configure IIS on the Keyfactor Command server to recognize the client certificate for authentication and then use basic authentication credentials on the Keyfactor Command server to provide authorization to Keyfactor Command. In addition, you will need to configure Keyfactor Command to force it to use the client certificate from the orchestrator stored in the header to authenticate the orchestrator, not the client certificate presented by the proxy in the second hop of the transaction.

Install the Required Windows Module

On your Keyfactor Command server, install the following additional module:

- *IIS Client Certificate Mapping Authentication* (rather than *Client Certificate Mapping Authentication*)

> **Tip:** It's fine to install both *IIS Client Certificate Mapping Authentication* and *Client Certificate Mapping Authentication*, but the former is what's needed for this solution.

If you have more than one Keyfactor Command server with separated roles, this only needs to be installed on the server accepting traffic to the /KeyfactorAgents web application.

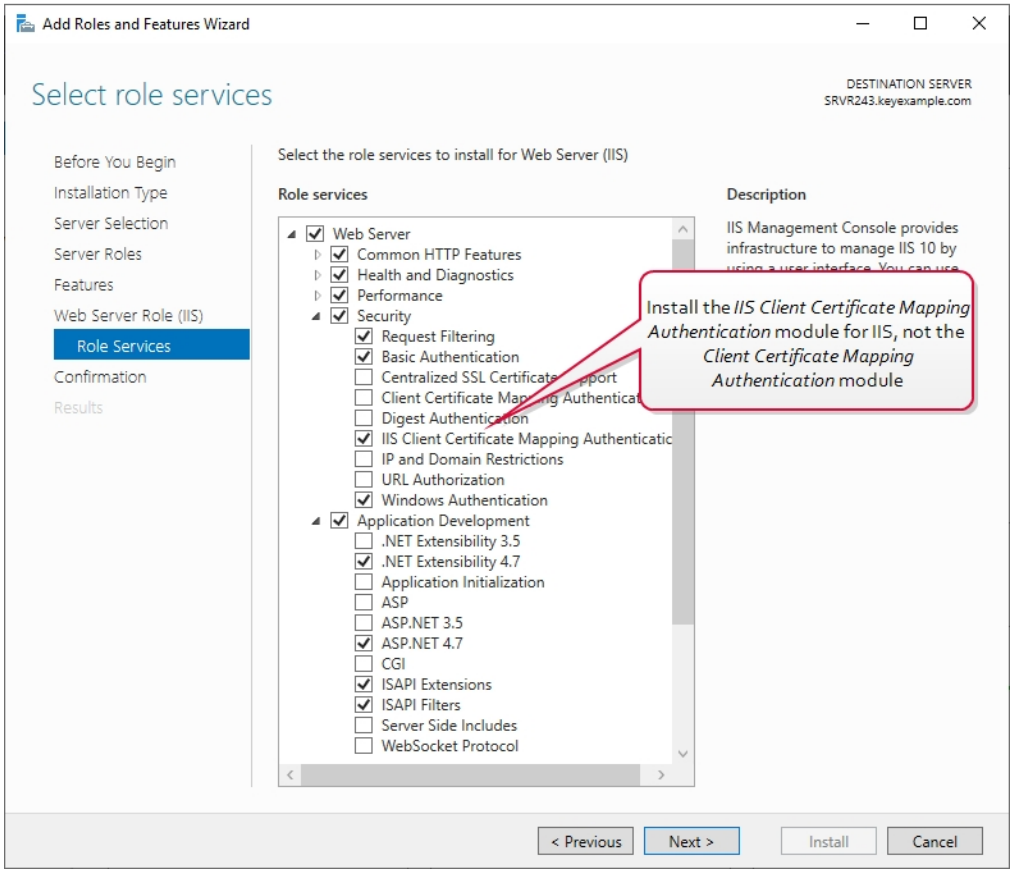

Figure 558: IIS Module for Client Certificate Authentication

The PowerShell command to install the appropriate module is :

```
Add-WindowsFeature Web-Cert-Auth
```

Configure Certificate Authentication and SSL Settings in IIS

Make the following changes in the IIS Management console on the Keyfactor Command server:

1. In the IIS Management console, highlight the server name on the left and open Authentication. Make sure *Anonymous Authentication* is the only enabled method.

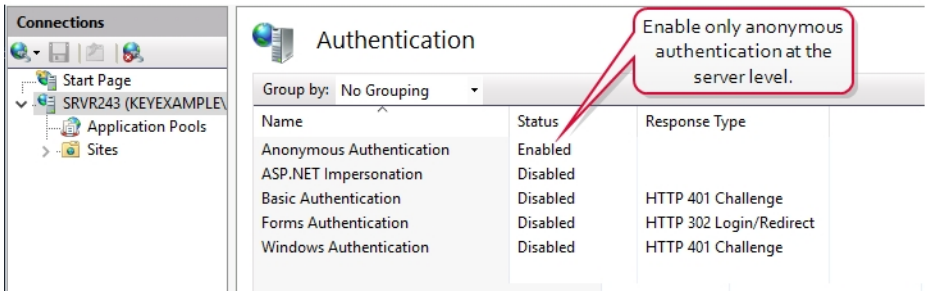

Figure 559: Configure only Anonymous Authentication at the Server Level in IIS

2. In the IIS Management console, drill down into sites and into the Default Web Site (or other web site if your Keyfactor Command instance has been installed in an alternate web site). Under the Default Web Site, locate the KeyfactorAgents application and open Authentication for this. Disable all the authentication methods shown here.

Figure 560: Disable Authentication Methods at the Application Level in IIS

Tip: If your KeyfactorAgents endpoint is running on a standalone server with no other Keyfactor roles, you should also disable all authentication methods at the Default Web Site level as in step two. If your server holds other Keyfactor roles, leave this in the default configuration with Anonymous being the only authentication method enabled as in step one.

3. In the IIS Management console, open SSL Settings for the KeyfactorAgents application. Check the **Require SSL** box and select either **Require** or **Accept** for *Client certificates*.

Important: Only selected **Require** if your are only using orchestrators that support client certificate authentication and plan to configure all of them for certificate authentication.

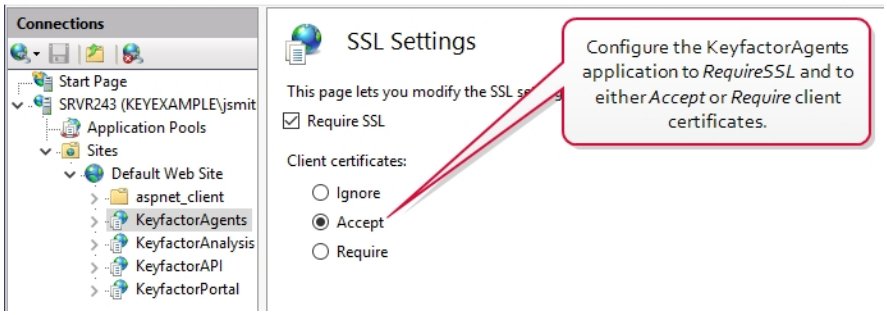

Figure 561: Configure SSL Settings in IIS for Client Certificate Authentication

Tip: If your KeyfactorAgents endpoint is running on a standalone server with no other Keyfactor roles, you may also configure your server to **Require** or **Accept** for *Client certificates* at the Default Web Site level. It is good security practice to check the *Require SSL* box. If your KeyfactorAgents endpoint is running on a server with other Keyfactor roles, you do not need to accept client certificates at this level and should not require them at this level.

Configure Basic Authentication Credentials in IIS

Make the following changes in the IIS Management console on the Keyfactor Command server:

1. In the IIS Management console, drill down to the Default Web Site (or other web site if your Keyfactor Command instance has been installed in an alternate web site). In the Default Web Site, open the Configuration Editor tool.

2. In the Configuration Editor tool at the Default Web Site level, browse to:

   system.webServer/security/authentication/iisClientCertificateMappingAuthentication

   Important: Don't be tempted to configure this setting only at the application level (KeyfactorAgents) rather than at the Default Web Site level. It will only work if configured at the Default Web Site level and then enabled at the application level.

3. In the configurations for IIS Client Certificate Mapping Authentication, set the *defaultLogonDomain* to your forest root. Set the *manyToOneCertificateMappingsEnabled* option to *True* and the *oneToOneCertificateMappingEnabled* option to *False*. Click the dots to the right of the *manyToOneMappings* setting to open details for this setting.

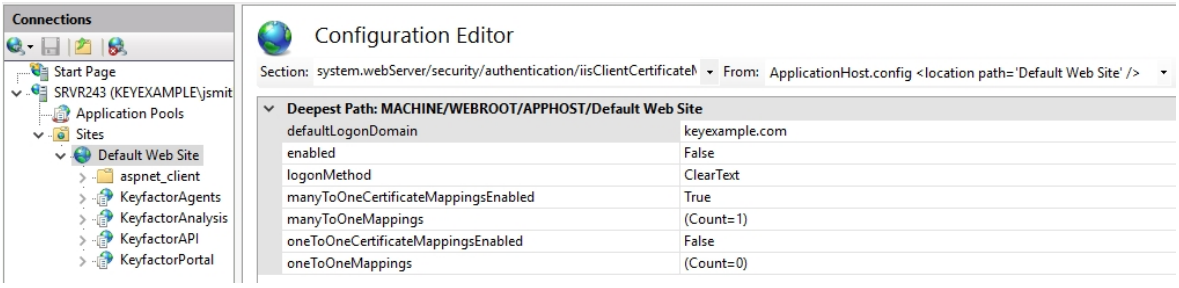

Figure 562: Configure IIS Client Certificate Mapping Authentication for the Default Web Site

4. In the Collection Editor for the manytoOneMappings, click **Add** and enter appropriate values for the properties. The service account entered here will be used as the identity in Keyfactor Command of all orchestrators that authenticate via client certificate.

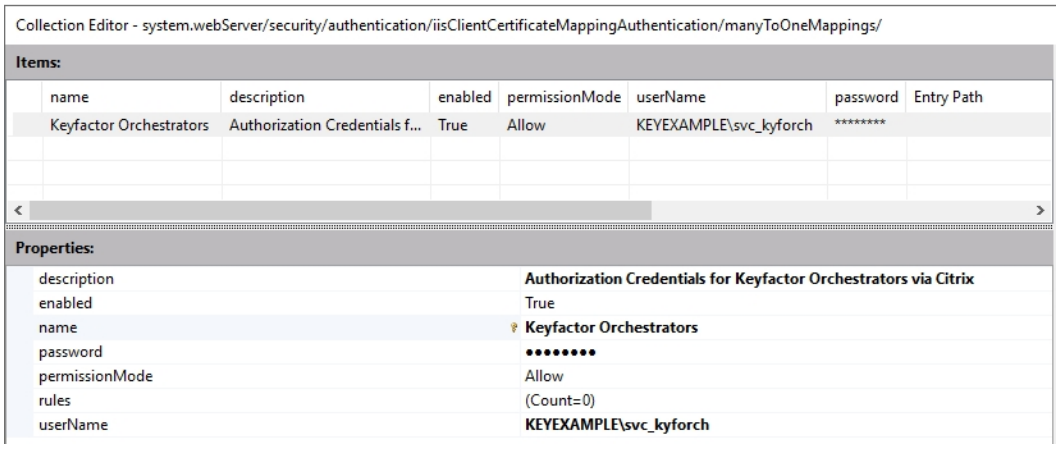

Figure 563: Configure Authorization Credentials for Keyfactor Orchestrators

5. In the IIS Management console,drill down into sites and into the Default Web Site (or other web site if your Keyfactor Command instance has been installed in an alternate web site). Under the Default Web Site, locate the KeyfactorAgents application and open the Configuration Editor tool for it.

6. In the Configuration Editor tool at the KeyfactorAgents application level, browse to:

   system.webServer/security/authentication/iisClientCertificateMappingAuthentication

   Enable the mapping authentication option at this level. The configuration should have replicated down from the Default Web Site level.

Configure the Keyfactor Command Application Setting to Use the Certificate from the Header

When the orchestrator is configured to use a client certificate to authenticate to a proxy and then the proxy is configured to use a separate client certificate to authenticate to the Keyfactor Command server, authentication to the Keyfactor Command application should be done using the original certificate from the orchestrator, not

the certificate inserted in the process at the proxy level. This is done by including the original certificate from the orchestrator in the request header to Keyfactor Command. To assure that Keyfactor Command gives priority to this certificate and not the certificate the proxy uses to authenticate, set the Keyfactor Command authentication application setting *Always Use Certificate from Header* to *True*.

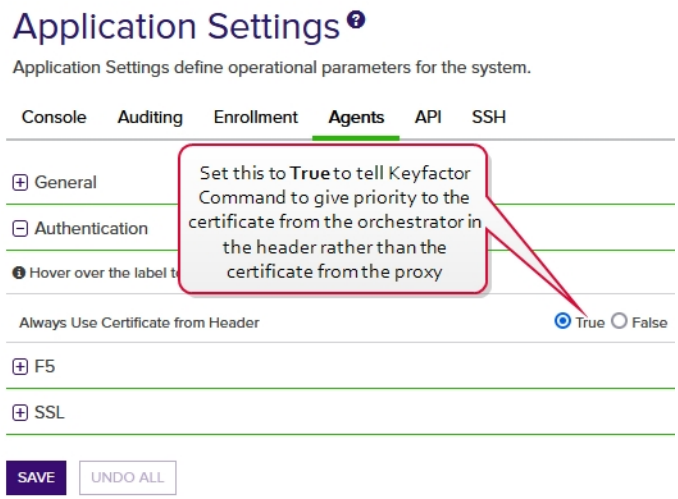

Figure 564: Configure Application Setting in Keyfactor Command to use the Header Certificate

Tip: In some proxy configurations, the proxy may be unable to negotiate the client certificate handshake with IIS. IIS won't ask directly for a client certificate, and if, during the handshake, the proxy doesn't send one, the client authentication will fail. If this occurs, you may need to enable client certificate negotiation at a lower level below IIS. To do this:

1. On the Keyfactor Command server, open a command prompt using the "Run as administrator" option.
2. Execute the following command to output the current configuration for SSL certificate bindings:

   ```
   netsh http show sslcert
   ```

   Output from this command will look something like this (you may see multiple sections if you have multiple web sites on the server):

   ```
   SSL Certificate bindings:
   -------------------------
   IP:port                      : 0.0.0.0:443
   Certificate Hash             : 649dfa6df693583f609af499fe4237f2c1d64224
   Application ID               : {4dc3e181-e14b-4a21-b022-59fc669b0914}
   Certificate Store Name       : My
   Verify Client Certificate Revocation : Enabled
   Verify Revocation Using Cached Client Certificate Only : Disabled
   Usage Check                  : Enabled
   ```

```
Revocation Freshness Time    : 0
URL Retrieval Timeout        : 0
Ctl Identifier               : (null)
Ctl Store Name               : (null)
DS Mapper Usage              : Enabled
Negotiate Client Certificate : Disabled
Reject Connections           : Disabled
Disable HTTP2                : Not Set
Disable QUIC                 : Not Set
Disable TLS1.2               : Not Set
Disable TLS1.3               : Not Set
Disable OCSP Stapling        : Not Set
Disable Legacy TLS Versions  : Not Set
```

3. Look at the value for the *Negotiate Client Certificate* setting for the web site on which Keyfactor Command is installed. If the value is *Disabled*, retrieve from the output the values for the *IP:port*, *Certificate Hash*, and *Application ID*.

4. Execute the following commands to remove and re-add the *IP:port* with *Negotiate Client Certificate* enabled (referencing the correct values for ipport, certhash, and appid):

    ```
    netsh http delete sslcert ipport=0.0.0.0:443
    netsh http add sslcert ipport=0.0.0.0:443
    certhash=649dfa6df693583f609af499fe4237f2c1d64224 appid={4dc3e181-e14b-4a21-
    b022-59fc669b0914} clientcertnegotiation=enable
    ```

5. Execute the *show* command again to confirm that the setting is now shown as enabled.

6. Restart the IIS services (iisreset) and try the certificate authentication again.

5.6.3 Appendix - Set up the Universal Orchestrator to Use Client Certificate Authentication with Certificates Stored in Active Directory

The Keyfactor Universal Orchestrator can be configured to support client certificate authentication by acquiring a certificate for the Keyfactor Command connect service account user or machine account of the orchestrator and storing it in Active Directory and then providing the associated Active Directory credentials to authenticate to Keyfactor Command. This has an advantage over the reverse proxy method (see Appendix - Set up the Universal Orchestrator to Use Client Certificate Authentication via a Reverse Proxy: Citrix ADC on page 2462) in that a username and password do not need to be stored anywhere (other than in Active Directory). This method does have a heavier reliance on Active Directory.

Complete the following steps and then configure the orchestrator to enable client certificate authentication as per the installation instructions (see -ClientCertificate on page 2376 or Install the Universal Orchestrator on Linux on page 2382).

Tip: Using this method, you do not necessarily need to configure certificate authentication in Keyfactor Command, unlike for the proxy method (see Appendix - Set up the Universal Orchestrator to Use Client Certificate Authentication via a Reverse Proxy: Citrix ADC on page 2462), since the certificate authentication is occurring at the IIS layer before the request reaches Keyfactor Command. You may wish to configure certificate authentication in Keyfactor Command to allow Keyfactor Command to monitor certificate authentication and to support automated certificate renewal (see Register a Client Certificate Renewal Extension on page 2406). If you enable certificate authentication in Keyfactor Command with this method, you will need to provide a value in the *Certificate Authentication HTTP Header* field. This header field is used to pass the certificate contents to Keyfactor Command command in instances when the certificate is not used directly (such as in the reverse proxy scenario). The value is required when configuring certificate authentication in Keyfactor Command, but since for this method you do not need to extract the certificate from the header, the value you set here is unimportant.

Important: If you do opt to enable certificate authentication in Keyfactor Command, be aware that this will force all orchestrators to use certificate authentication when communicating with Keyfactor Command on the configured server.

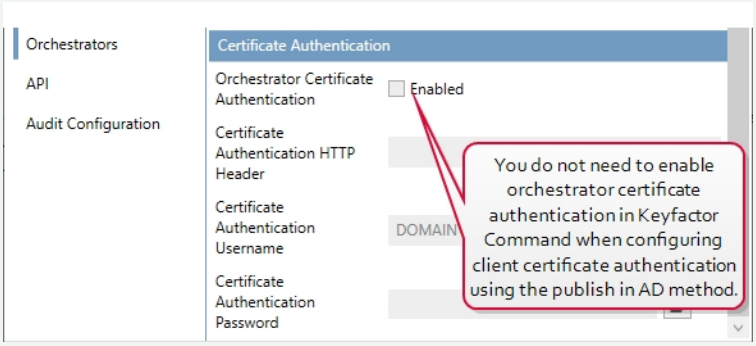

Figure 565: Client Certificate Authentication with AD Storage Does Not Require Certificate Authentication Configuration in Keyfactor Command

Note: The following instructions assume that your Keyfactor Command server is already installed and configured with an SSL certificate that is trusted in your environment. If this is not the case, this will also need to be done.

Install the Required Windows Module

On your Keyfactor Command server, install the following additional module:

- *Client Certificate Mapping Authentication* (rather than *IIS Client Certificate Mapping Authentication*)

If you have more than one Keyfactor Command server with separated roles, this only needs to be installed on the server accepting traffic to the /KeyfactorAgents web application.

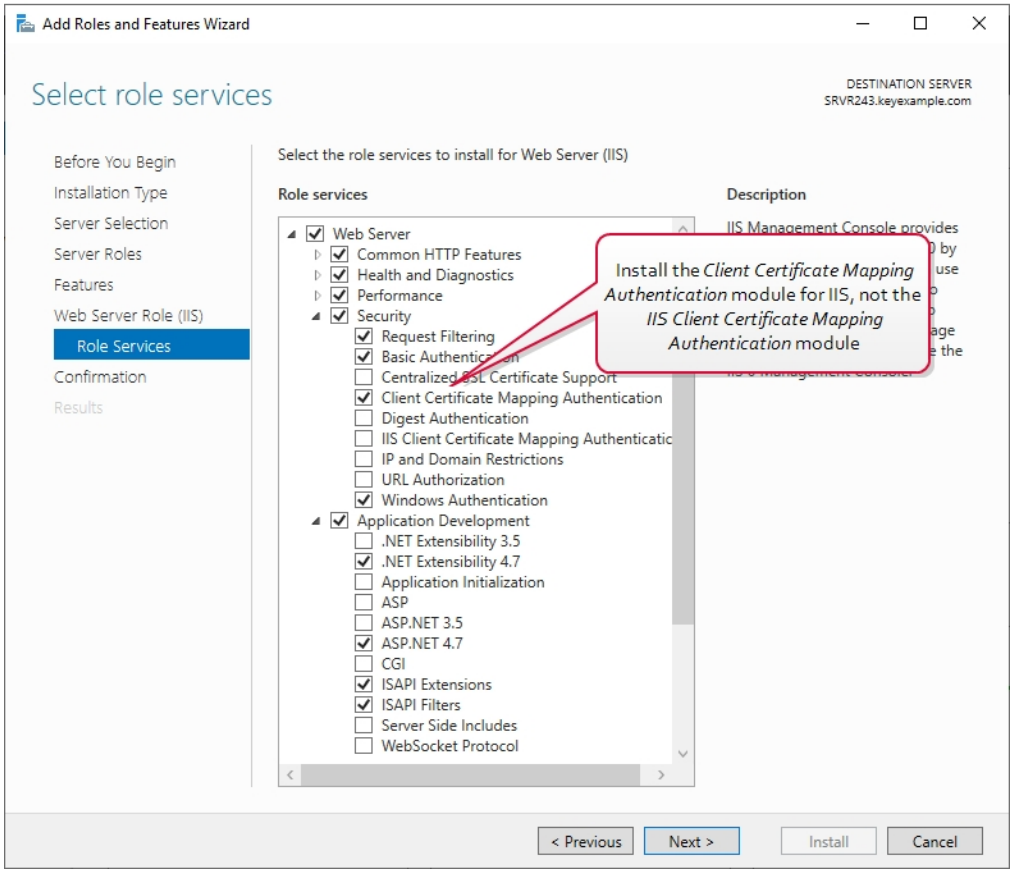

Figure 566: IIS Module for Client Certificate Authentication with AD Storage

The PowerShell command to install the appropriate module is :

```
Add-WindowsFeature Web-Client-Auth
```

Configure Certificate Authentication and SSL Settings in IIS

Make the following changes in the IIS Management console on the Keyfactor Command server:

1. In the IIS Management console, highlight the server name on the left and open Authentication. Change the status of *Active Directory Client Certificate Authentication* to **Enabled**.

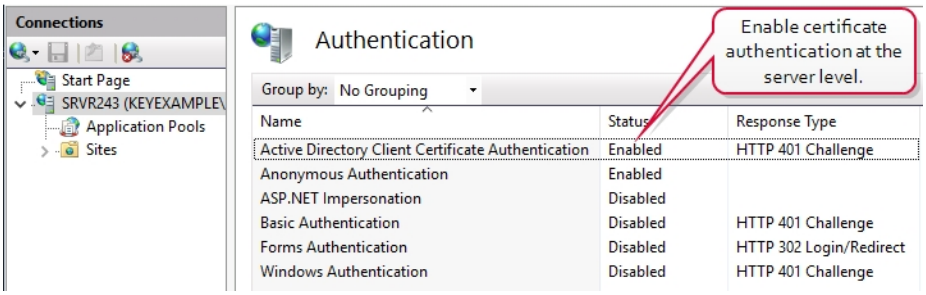

Figure 567: Configure Client Certificate Authentication at the Server Level in IIS

2. In the IIS Management console, drill down into sites and into the Default Web Site (or other web site if your Keyfactor Command instance has been installed in an alternate web site). Under the Default Web Site, locate the KeyfactorAgents application and open Authentication for this. Disable all the authentication methods shown here. The *Active Directory Client Certificate Authentication* method does not appear here.

Figure 568: Disable Authentication Methods at the Application Level in IIS

Tip: At the Default Web Site level, the only authentication method that should be enabled is Anonymous. This should not be changed.

3. In the IIS Management console, open SSL Settings for the KeyfactorAgents application. Check the **Require SSL** box and select either **Require** or **Accept** for *Client certificates*.

Important: Only selected **Require** if your are only using orchestrators that support client certificate authentication and plan to configure all of them for certificate authentication.

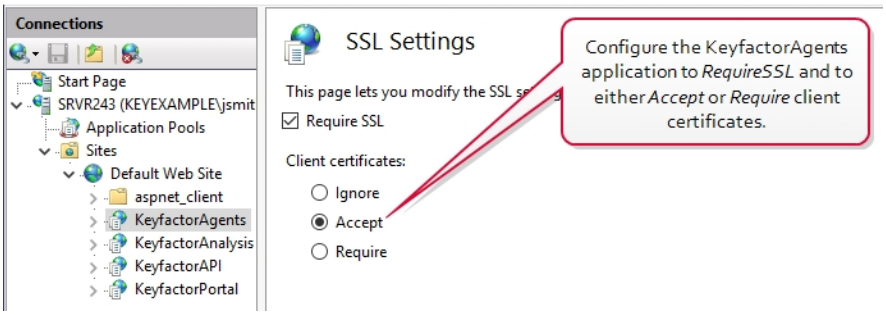

Figure 569: Configure SSL Settings in IIS for Client Certificate Authentication

Tip: At the Default Web Site level, it is good security practice to check the *Require SSL* box, but you do not need to accept client certificates at this level and should not require them at this level.

Create a Certificate Template for Orchestrator Certificates

This method of certificate authentication functions by sending a client certificate from the orchestrator to IIS on the Keyfactor Command server, where IIS does a lookup in Active Directory to determine what Active Directory user is associated with that certificate and then turns around and uses that identity to connect to Keyfactor Command. In order for the certificate to the associated with the Active Directory identity, it must be enrolled using a template that has the *Publish certificate in Active Directory* option enabled.

To create the certificate template that will be used for orchestrator client authentication certificates, start by duplicating a template with a *Computer* subject type. In addition to any standards for your environment, the templates needs:

- The *Publish certificate in Active Directory* box checked.

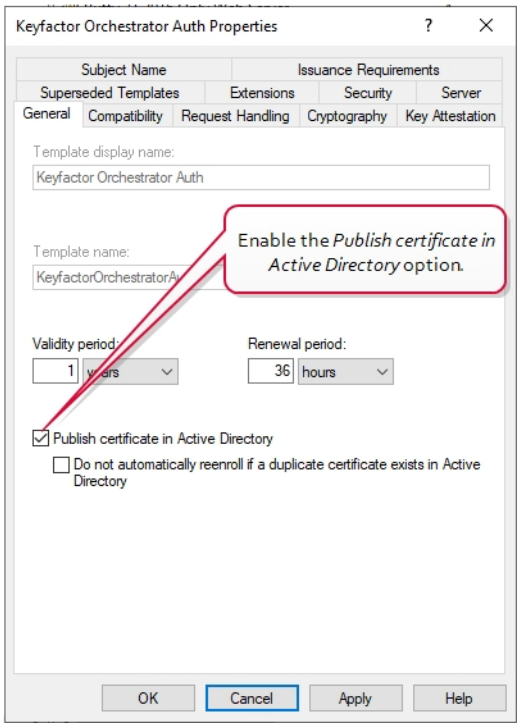

Figure 570: Microsoft Certificate Template General for Client Authentication Certificate

- A key usage that includes Digital Signature.

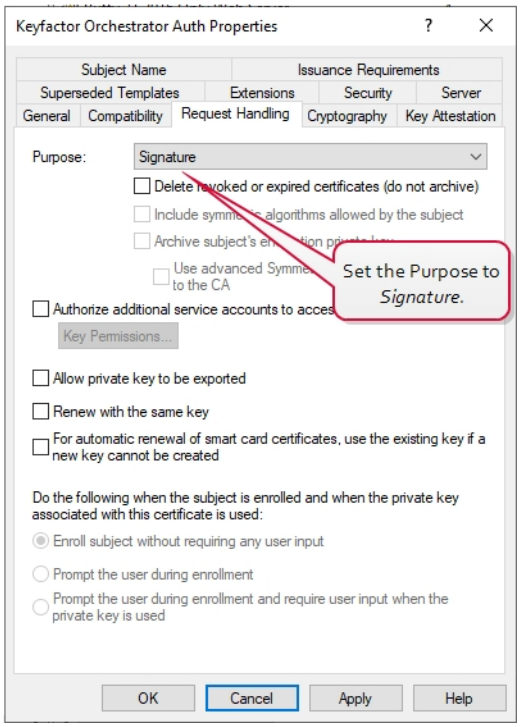

Figure 571: Microsoft Certificate Template Request Handling for Client Authentication Certificate

- An extended key usage (EKU) of Client Authentication.

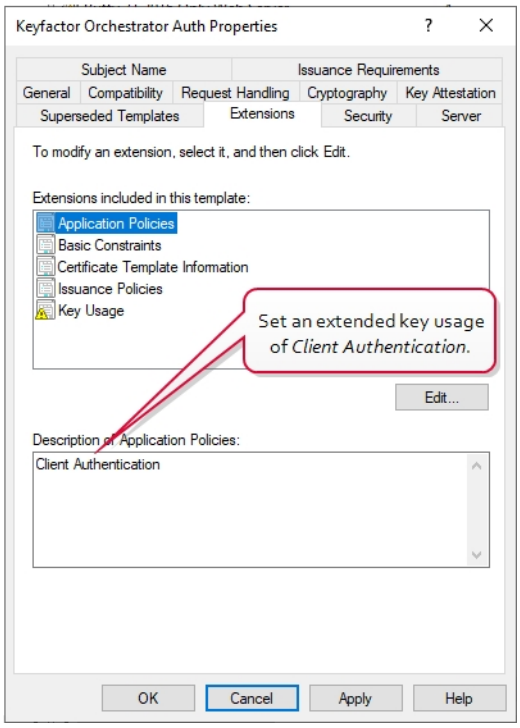

Figure 572: Microsoft Certificate Template Application Policies for Client Authentication Certificate

- Enroll permissions for either the service account that the orchestrator will run as or the machine account for the orchestrator machine (see).

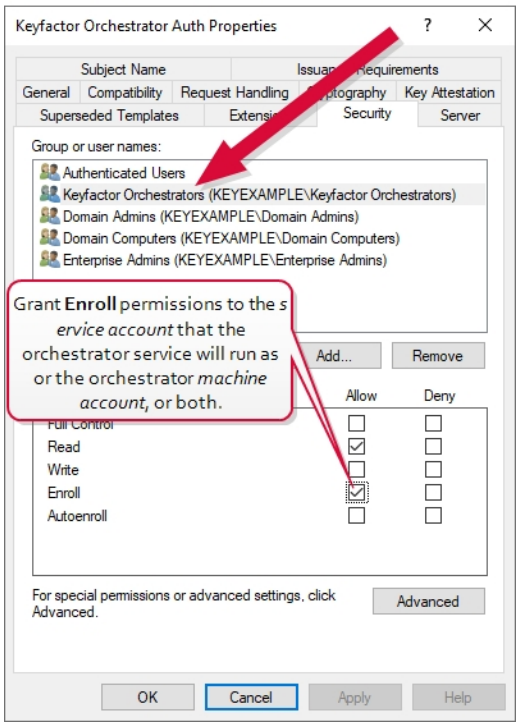

Figure 573: Microsoft Certificate Template Security for Client Authentication Certificate

Enroll for a Client Authentication Certificate

To acquire a certificate for use by the Universal Orchestrator using a Microsoft CA, first create a template using the appropriate configurations as described above and make it available for enrollment on a CA to which the Universal Orchestrator machine has access. If you plan to enroll for the certificate through Keyfactor Command, you will also need to enable the template for enrollment in Keyfactor Command.

You can enroll for a client authentication certificate for the orchestrator in a variety of ways. The certificate needs to be installed in the **local computer** personal store on the Windows server on which the orchestrator is installed. Some possible ways to do this are:

- Use Keyfactor Command to enroll for the certificate using the PFX enrollment method and then import the PFX file on the orchestrator server. If you select this method, you will need to login to the Keyfactor Command Management Portal as the orchestrator service account being used on the Keyfactor Command side of the fence (see Create Service Accounts for the Universal Orchestrator on page 2362) in order to enroll for the certificate in the correct context or use the Keyfactor API to submit a request in a specific user context (see PFX Enrollment in Keyfactor Command Using a PowerShell Script on the next page). The orchestrator service account will need enroll permissions on the CA, on the template, and in Keyfactor Command.
- Use IIS or the certificates MMC on the orchestrator server to generate a CSR, use the Keyfactor Command CSR enrollment method to enroll for a certificate using the CSR, and then import the CSR on the orchestrator server, marrying it with the private key generated on the server. If you select this method, you will need to login to the Keyfactor Command Management Portal as the orchestrator service account being used on the Keyfactor Command side of the fence (see Create Service Accounts for the Universal Orchestrator on

page 2362) in order to enroll for the certificate in the correct context. The orchestrator service account will need enroll permissions on the CA, on the template, and in Keyfactor Command.

- If there is an existing Universal Orchestrator on the server already running and communicating with Keyfactor Command, use the Keyfactor Command PFX enrollment method and push the certificate out to the certificate store on the orchestrator server using Keyfactor Command. If you select this method, you will need to login to the Keyfactor Command Management Portal as the orchestrator service account being used on the Keyfactor Command side of the fence (see Create Service Accounts for the Universal Orchestrator on page 2362) in order to enroll for the certificate in the correct context or use the Keyfactor API to submit a request in a specific user context (see PFX Enrollment in Keyfactor Command Using a PowerShell Script below). The orchestrator service account will need enroll permissions on the CA, on the template, and in Keyfactor Command.
- Use the Microsoft MMC on the orchestrator server to enroll for a certificate. If you select this method, the orchestrator will connect to Keyfactor Command using the orchestrator machine account rather than an Active Directory user account. The orchestrator machine account will need enroll permissions on the CA and on the template. This method will only work for servers joined to the same Active Directory forest in which Keyfactor Command is installed.

PFX Enrollment in Keyfactor Command Using a PowerShell Script

To enroll for a certificate using the PFX enrollment method in Keyfactor Command, you can either do this in the Keyfactor Command Management Portal while logged in as the orchestrator service account or with a PowerShell script. In either case, the orchestrator service account will need PFX enroll permissions in Keyfactor Command. Below is a sample PowerShell script. Once the PFX file has been generated, import it into the local machine store on the orchestrator server.

Tip: The service account you provide in the PowerShell script is the service account used to provide a connection from the orchestrator to Keyfactor Command. This is not necessarily the same service account that runs the orchestrator service on the orchestrator server. For an orchestrator in a separate forest from Keyfactor Command, this would be a service account in the Keyfactor Command forest, not the orchestrator forest. See Create Service Accounts for the Universal Orchestrator on page 2362.

```
#Set variables with the username and password for the orchestrator service account
$orchUsername = 'KEYEXAMPLE\svc_kyforch'
$orchPassword = 'MySecureServiceAccountPassword'
$pair = "$($orchUsername):$($orchPassword)"

# Base-64 encode the service account credentials
$encodedCreds = [System.Convert]::ToBase64String([System.Text.Encoding]::ASCII.GetBytes($pair))

$UTCTime = (Get-Date).ToUniversalTime().ToString("yyyy-MM-ddTHH:mm:ssZ")
$keyfactorServer = 'keyfactor.keyexample.com' # FQDN of the Keyfactor Command server
$caName = 'corpca01.keyexample.com\CorpIssuing01' # CA to use for the enrollment
$templateName = 'KeyfactorOrchestratorAuth' # Template to use for the enrollment
$certSubject = 'Orchestrator Cert Auth' # Using a template that is configured to build from AD will
```

```
cause this subject to be replaced
$pfxPassword = 'MySecurePFXPassword' # Password for the resulting PFX file
$outputFile = 'C:\stuff\OrchCertAuth.pfx' # Path and file name for the PFX file to be generated

$basicAuthValue = "Basic $encodedCreds"

$headers = @{
"Authorization"=$basicAuthValue
"Accept"="application/json"
"x-keyfactor-requested-with"="APIClient"
"x-certificateformat"="PFX"
}

$body = @{
"Password" = "$pfxPassword"
"Subject" = "$certSubject"
"IncludeChain" = "true"
"CertificateAuthority" = "$caName"
"Timestamp" = "$UTCTime"
"Template" = "$templateName"
}

# Output response as a PFX file
$response = Invoke-WebRequest -Uri "https://$keyfactorServer/KeyfactorAPI/Enrollment/PFX" -Meth-
od:Post -Headers $headers -ContentType "application/json" -Body ($body|ConvertTo-Json) -ErrorAc-
tion:Stop -TimeoutSec 60
$ResponseContent = $response.Content | ConvertFrom-Json
$bytes = [Convert]::FromBase64String($ResponseContent.CertificateInformation.Pkcs12Blob)
[IO.File]::WriteAllBytes($outputFile, $bytes)
```

PFX Enrollment and Deployment in Keyfactor Command Using a PowerShell Script

To enroll for a certificate using the PFX enrollment method in Keyfactor Command and deploy it to the orchestrator server using Keyfactor Command, you can either do this in the Keyfactor Command Management Portal while logged in as the orchestrator service account or with a PowerShell script. In either case, the orchestrator service account will need PFX enroll permissions and certificate store management permissions in Keyfactor Command. Below is a sample PowerShell script. This solution is only an option if your orchestrator is already up and running and successfully authenticating to Keyfactor Command using standard authentication (or previously configured certificate authentication).

Tip: The service account you provide in the PowerShell script is the service account used to provide a connection from the orchestrator to Keyfactor Command. This is not necessarily the same service account that runs the orchestrator service on the orchestrator server. For an orchestrator in a separate

forest from Keyfactor Command, this would be a service account in the Keyfactor Command forest, not the orchestrator forest. See Create Service Accounts for the Universal Orchestrator on page 2362.

```
#Set variables with the username and password for the orchestrator service account
$orchUsername = 'KEYEXAMPLE\svc_kyforch'
$orchPassword = 'MySecureServiceAccountPassword'
$pair = "$($orchUsername):$($orchPassword)"

# Base-64 encode the service account credentials
$encodedCreds = [System.Convert]::ToBase64String([System.Text.Encoding]::ASCII.GetBytes($pair))

$UTCTime = (Get-Date).ToUniversalTime().ToString("yyyy-MM-ddTHH:mm:ssZ")
$keyfactorServer = 'keyfactor.keyexample.com' # FQDN of the Keyfactor Command server
$storeName = 'websrvr38.keyexample.com' # FQDN of the orchestrator server as defined as a certificate store in Keyfactor Command
$caName = 'corpca01.keyexample.com\CorpIssuing01' # CA to use for the enrollment
$templateName = 'KeyfactorOrchestratorAuth' # Template to use for the enrollment
$certSubject = 'Orchestrator Cert Auth' # Using a template that is configured to build from AD will cause this subject to be replaced

$basicAuthValue = "Basic $encodedCreds"

$enrollHeaders = @{
   "Authorization"=$basicAuthValue
   "Accept"="application/json"
   "x-keyfactor-requested-with"="APIClient
   "x-certificateformat"="Store"
}

$deployHeaders = @{
   "Authorization"=$basicAuthValue
   "Accept"="application/json"
   "x-keyfactor-requested-with"="APIClient"
}

$enrollBody = @{
   "Subject" = "$certSubject"
   "IncludeChain" = "true"
   "CertificateAuthority" = "$caName"
   "Timestamp" = "$UTCTime"
   "Template" = "$templateName"
}
```

```
# Enroll for a certificate using the PFX enrollment method and retrieve the certificate ID from the
response (as part of the content)
$enrollResponse = Invoke-WebRequest -Uri "https://$keyfactorServer/KeyfactorAPI/Enrollment/PFX" -
Method:Post -Headers $enrollHeaders -ContentType "application/json" -Body ($enrollBody|ConvertTo-
Json) -ErrorAction:Stop -TimeoutSec 60
$enrollContent = $enrollResponse.Content | ConvertFrom-Json

# Get the store GUID for the certificate store specified by the client machine name in the query
string with the storeName variable
$storeInfo = Invoke-WebRequest -Uri "https://$key-
factorServer/KeyfactorAPI/CertificateStores?certificateStoreQuery.queryString=ClientMachine%20-
eq%20%22$storeName%22" -Method:Get -Headers $deployHeaders -ContentType "application/json" -
ErrorAction:Stop -TimeoutSec 60
$storeContent = $storeInfo.Content | ConvertFrom-Json
$storeGUID = $storeContent.Id

$deployBody = @{
   "StoreIds" = @( "$storeGUID" )
   "StoreTypes" = @(
      @{
         "StoreTypeId" = 6 # Store type 6 is IIS personal
         "Overwrite" = "false"
      }
   )
   "CertificateId" = $enrollContent.CertificateInformation.KeyfactorId
}

# Deploy certificate to certificate store
Invoke-WebRequest -Uri "https://$keyfactorServer/KeyfactorAPI/Enrollment/PFX/Deploy" -Method:Post -
Headers $deployHeaders -ContentType "application/json" -Body ($deployBody|ConvertTo-Json) -ErrorAc-
tion:Stop -TimeoutSec 60
```

MMC Enrollment

To enroll for a certificate using the MMC:

1. On the Universal Orchestrator machine, do one of following:
    - Using the GUI:
        a. Open an empty instance of the Microsoft Management Console (MMC).
        b. Choose **File->Add/Remove Snap-in…**.
        c. In the *Available snap-ins* column, highlight **Certificates** and click **Add**.

d. In the Certificates snap-in popup, choose the radio button for Computer account, click **Next**, accept the default of Local computer, and click **Finish**.

e. Click **OK** to close the Add or Remove Snap-ins dialog.

- Using the command line:
  a. Open a command prompt using the "Run as administrator" option.

  b. Within the command prompt type the following to open the certificates MMC:
  certlm.msc

2. Drill down to the Personal folder under **Certificates** for the Local Computer, right-click, and choose **All Tasks->Request New Certificate…**.

3. Follow the certificate enrollment wizard, selecting the template you created for orchestrator certificate authentication and providing any required information.

Grant the Service Account Certificate Private Key Permissions

Whichever method you decide to use to acquire the client authentication certificate for the orchestrator, you will need to grant the Universal Orchestrator service account—the account that the orchestrator service is running as on the server—permissions to read the private key of that certificate.

Tip: If the service account is a member of the local administrators group, this step may not be necessary, since the local administrators group is typically granted these permissions automatically.

To grant private key permissions on the certificate using the MMC:

1. On the Universal Orchestrator machine, do one of following:
   - Using the GUI:
     a. Open an empty instance of the Microsoft Management Console (MMC).

     b. Choose **File->Add/Remove Snap-in…**.

     c. In the *Available snap-ins* column, highlight **Certificates** and click **Add**.

     d. In the Certificates snap-in popup, choose the radio button for Computer account, click **Next**, accept the default of Local computer, and click **Finish**.

     e. Click **OK** to close the Add or Remove Snap-ins dialog.

   - Using the command line:
     a. Open a command prompt using the "Run as administrator" option.

     b. Within the command prompt type the following to open the certificates MMC:
     certlm.msc

2. Drill down to the Personal folder under **Certificates** for the Local Computer to locate the certificate.

3. Highlight the certificate and choose **All Tasks->Manage Private Keys…**.

4. In the Permissions for private keys dialog, click **Add**, add the service account under which the Universal Orchestrator is running (created as per Create Service Accounts for the Universal Orchestrator on page 2362), and grant that service account **Read** but not **Full control** permissions. Click **OK** to save.

Tip: If you receive the following error when selecting your certificate in the orchestrator configuration wizard:

```
The request was aborted: Could not create SSL/TLS secure channel.
```

- Confirm that the orchestrator server trusts the root and issuing certificates for the SSL certificate on the Keyfactor Command server and the client authentication certificate you are trying to use (see Configure Certificate Root Trust for the Universal Orchestrator on page 2365).
- Confirm that the orchestrator server has access to the CRLs for both the SSL certificate on the Keyfactor Command server and the client authentication certificate you are trying to use and that these CRLs are valid.
- Confirm that you have granted the service account under which the orchestrator service runs private key permissions on the client authentication certificate.

5.6.4 Appendix - Set up the Universal Orchestrator to Use a Forwarding Proxy

Typically with services that use a forwarding proxy, there is a specific proxy configuration done within the application, but the Universal Orchestrator doesn't have such a configuration. Instead, it makes use of an environment variable to retrieve this information on either Windows or Linux.

On Windows, configure a system environment variable of either HTTP_PROXY or HTTPS_PROXY (this is not case sensitive on Windows) pointing to your proxy's URL, including port, then restart the Universal Orchestrator service if the orchestrator is already installed.

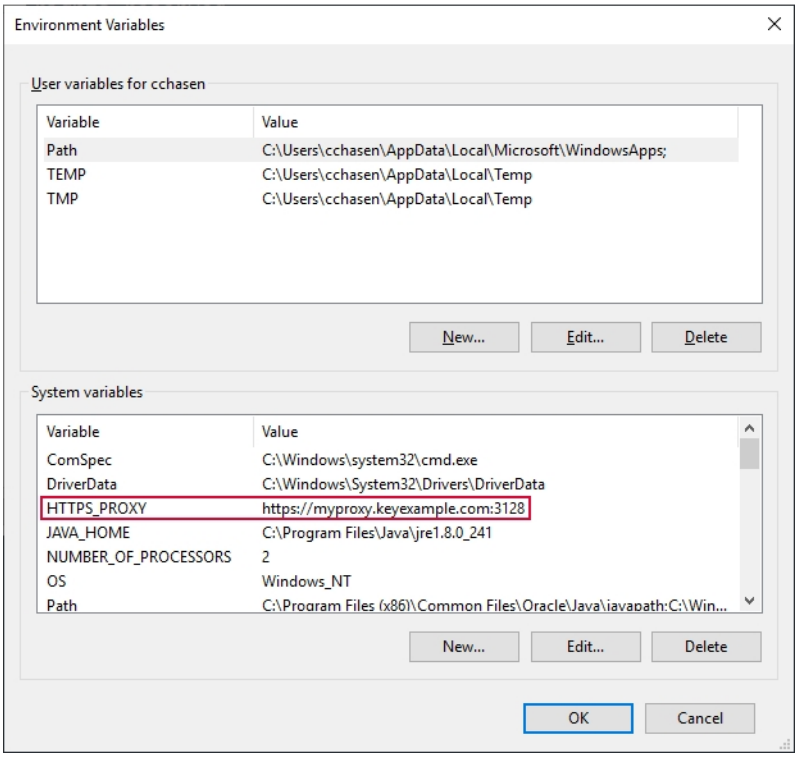

Figure 574: System Environment Variable to Define a Proxy URL for Use by the Universal Orchestrator on Windows

On Linux, there are multiple approaches to setting an environment variable. One method for setting a system-wide environment variable that will be retained after reboot is to add an environment variable statement to the /etc/environment file using a command similar to the following (as root):

```
echo https_proxy=https://myproxy.keyexample.com:3128/" >> /etc/environment
```

After setting the environment variable, restart the Universal Orchestrator service if the orchestrator has already been installed.

6.0 Release Notes

The Keyfactor Command suite of documentation is released as both major releases, with version numbers ending in zero, and minor releases, with incremental fixes and updates following the major release. When reviewing release notes, be sure to review those for both the minor releases and their corresponding major release.

6.1 Major Release 10.0 Notes

September 2022

We're thrilled to announce Keyfactor Command 10.0, which includes some major new features and updates to improve the user experience, enhance automation, and provide native integration with EJBCA.

Important: The MicrosoftECCurveUpgradeModule may fail due to a pre-v10 issue in which Certificate Request Contents were truncated to 4k characters when saved to the database. If your upgrade fails when the MicrosoftECCurveUpgradeModule is run contact Keyfactor Support to obtain assistance with the scripts that will have to be run to fix this issue.

Tip: We encourage customers to contact their customer success manager to discuss the new features and functionality in Keyfactor Command 10, and to schedule an upgrade. Please refer to the *Keyfactor Command Upgrade Overview*[1] for important information about the upgrade process.

Highlights

Workflow Builder

Workflows in Keyfactor Command allow for automation and governance of certificate enrollment and revocation. The workflow builder makes it easy to define workflows within the Keyfactor Command Management Portal to automate event-driven tasks when a certificate is requested (including renewals) or revoked. The workflows can be built with multiple steps between the start and end of the operation that offer a simple way to send notifications, submit approvals, and configure end-to-end automation throughout the environment. This provides for operational agility in an intuitive and easy-to-user tool. Supported built-in steps that can be used in the workflow builder include one or more approval steps supporting one or more approvers, calls to REST APIs, calls to PowerShell, sending emails, and updating enrollment requests with changes to the submitted subject or SANs, if needed. Custom steps can also be built to address specific needs. The workflow builder provides an easy-to-use experience to create rich workflows with multiple steps.

[1]Embedded links to external documents point to the document on the Keyfactor Client Portal. Access to the portal requires a login. See your administrator or your Keyfactor Client Success representative to obtain a login to the portal.

EJBCA Integration with Keyfactor Command

EJBCA is a robust and highly scalable certificate authority. Keyfactor Command now natively integrates with EJBCA version 7.8.1 or higher without the need for a gateway, providing a simpler architecture. The Certificate Authorities area of Keyfactor Command now allows an administrator to enter connection information to an EJBCA CA to manage certificates and support enrollment. With native EJBCA integration, Keyfactor Command offers an alternative to Microsoft CAs. EJBCA is a much more scalable CA with options for multiple CAs on a single server and high availability configuration options that the Microsoft CA lacks. It can also handle a much larger number of certificates than the Microsoft CA.

CA Gateway 22.1 required for Keyfactor Command v10

Upgrade to AnyGateway 22.1 if using gateways on Keyfactor Command v10.

Expanded Template Functionality

- System-wide settings for enrollment templates have moved from the application settings to the templates page.
- Templates can be configured to set policies for the following at both the template level and the system-wide configuration level:
    - Allow Wildcards
    - Allow Public Key Reuse
    - Enforce RFC 2818 Compliance
    - Supported Key Types
- Added a new configuration tab at both the template level and the system-wide configuration level called "Enrollment Defaults" that allows for defining default values for select certificate subject parts that will auto-populate on the PFX Enrollment and CSR Generation pages.
- "Template RegExes" has been renamed to "Enrollment RegExes". Regular expressions for certificate subject values can be defined at both the template level and the system-wide configuration level.
- Metadata can be configured on a per-template basis to control which fields are shown during enrollment and what default values they have.
- When enrolling with the template, the key size of the request is validated against the template key size. This allows for a key size to be set on a template in Keyfactor Command for validation purposes that can be different than the CA template key size setting.
    - If a CSR Enrollment request is made with a key size that is not valid, per the template policy settings, an error will be displayed when you click the **Enroll** button (for example, the CSR has a key size of 2048 but the template policy supports only 4096).
    - For PFX Enrollment, the request will contain the minimum settings from the Keyfactor Command presiding template settings.

- During the upgrade process Keyfactor Command prevents duplicate template records from being inserted into the database. Duplicate templates could be found if there are templates in different forests with the same name. If you receive an error message during upgrade, contact Keyfactor Support. We will be able to support you through the process of resolving the issue and completing the upgrade. See the *Keyfactor Command Upgrade Overview* for more information.

Keyfactor API Endpoints

The Keyfactor API now has endpoints for most of the functionality found in the product. See the API Endpoint Change Log on page 2500 for information on new and updated API endpoints.

Updates

Changes & Improvements

- **CARecordID Replaces CARequestID**

  The field CARecordID has been added and the field CARequestID has been removed.

- ***Forest* has been Renamed *Configuration Tenant***
  - To broaden Keyfactor Command's compatibility with certificate authorities, the Microsoft-centric term "forest" has been renamed to "configuration tenant". For EJBCA, there should be one configuration tenant per EJBCA server install. For Microsoft, there should be one per forest. Note that configuration tenants cannot be mixed, so Microsoft and EJBCA CAs cannot exist on the same configuration tenant.
  - Added the ability to search templates by configuration forest and key type. The option to search by forest has been retained for backwards compatibility.

- **SQL Server Connection over SSL**

  As of Keyfactor Command version 10.0, by default Keyfactor Command connects to SQL using an encrypted connection using an SSL certificate configured on your SQL server. Customers should acquire and install an SSL certificate for the SQL server before upgrading to Keyfactor Command 10.0 (see Using SSL to Connect to SQL Server on page 2222 in the *Keyfactor Command Server Installation Guide*). If you would prefer not to use an encrypted channel for your connection to SQL, see Configurable SQL Connection Strings on page 2226.

- **SQL Encryption Key Backup**

  When Keyfactor Command is installed, the option is presented to make a backup of the SQL database master key (DMK). In previous versions of Keyfactor Command, this option backed up the service master key (SMK) instead. For more information about how Keyfactor Command uses the DMK and SMK, see SQL Encryption Key Backup on page 666 in the *Keyfactor Command Reference Guide*.

- **SQL Server 2022 Compatibility**

  Keyfactor Command is compatible with SQL Server 2022.

- **Certificate Requests**
  - The Certificate Requests page is now sorted in descending order by submission date by default. This has been done to cause the more recent requests to appear at the top of the page.

- The Certificate Requests page is now separated into tabs for pending, external validation, and denied/-failed certificate requests.
- The Denied/Failed tab on the Certificate Requests page now includes only certificate requests denied through Keyfactor Command (see Viewing Certificate Requests on page 147 in the *Keyfactor Command Reference Guide*).
- The Revoked view filter has been removed from the Certificate Requests page since the expectation is that Keyfactor Command workflows will be used for enrollments and the history can be viewed as part of that (see Workflow Instances on page 266 in the *Keyfactor Command Reference Guide*).

- **Alerts**
  - When an alert is copied, " - Copy" is appended to the display name to prevent alert display names being duplicated.
  - To aid in clarity, changed the wording on templates when configuring alerts from "None" to "All Templates".
- **SMTP Application Settings**

  When making changes to the SMTP configuration, the test email can be sent without saving the configuration changes.
- **Certificate Authorities**
  - Added an option to delegate enrollment requests to the Authorization Methods tab. This is in addition to the option to delegate management functions. This allows Keyfactor Command to delegate the authenticated user's credentials to the CA during enrollment to provide end-to-end authentication without unpacking the credentials at the Keyfactor Command layer. If this is not enabled the "Allowed Requesters" will be used instead. Please see the Authorization Methods Tab on page 322 in the *Keyfactor Command Reference Guide* for more information.
  - When configuring a new certificate authority in the Management Portal, there is now an option to test the connection to the CA before saving the configuration, and CAs will be tested and must be verified and valid to be saved.
  - Updated the CA synchronization so that it logs a message if it could not chain a certificate up to a CA in the system instead of throwing an error.
  - Added a new application setting, *CA Sync Consecutive Error Limit*, which controls the number of times an error can occur before the synchronization job is abandoned.
  - There is no longer the need to register offline CAs, as the root/policy CA certificates can be imported from the issuing CA sync without them. Additionally, the new CA validation makes it impossible to save offline CAs.
- **Certificate Stores**
  - Added the ability for users with only container-level permission to create and use certificate stores in the container, including certificate store types that have a server component. Users will not be able to access certificate stores outside of the containers they have permissions to manage. (Previously, users needed to have Certificate Store Manage permissions in order to change client machine credentials as certificate store servers was shared across all certificate stores with the same type and server name. Now, certificate store servers are partitioned by container.)

- Added the ability to import PEM certificates that have comments in them when doing an inventory of an F5 REST certificate store.
- On the Discover tab the label for "Approve" has been changed to "Manage" for clarity.

- **Dashboard and Reporting**
  - The Risk header can now be hidden via security role permissions.
  - Some cosmetic updates have been made to the Risk header.
  - The Collections Dashboard widget is limited to only displaying the first 25 collections configured to be on the dashboard. It sorts the list alphabetically.
  - The stale date is visible in the CRL Monitoring Dashboard widget as a new column and is called "Next Publish by Date". The stale date should not be used for calculating the status of the CRL. A stale CRL is a valid state and not something that needs to be warned on. If a CRL is stale, the system will check how far it is from expiration and if it is within the warning period it will have a status of "Warning" or "Valid" if outside the warning period.
  - Keyfactor Command v10 ships with a newer version of Logi Analytics (v14) which drives the Reports and Dashboards. This version provides a number of improvements and fixes some security vulnerabilities.
  - CRL dates are always shown in UTC on the Revocation Monitoring Dashboard.
  - A new report—SSH Key Usage—shows a table which displays a list of SSH keys that have not been used to log on in the given minimum number of days.
  - The Risk header on the dashboard has been updated to avoid awkward text formatting and scrolling when resizing the page.
  - The Risk header titles have been updated for consistency and clarity. "Expiring" titles are now all in the "Expiring" tense and consistent with each other. "Weak Keys" has been renamed to "Certs with Weak Keys".
  - The *Certificate Count by Template* has been updated so that it takes the same parameters as the *Certificate Count per User by Template* report for consistency. This included changing the "Evaluation Date" to "Start Date" and adding an "End Date" field.
  - All reports have been updated to reference UTC time to avoid confusion about which time zone is being applied.
  - The *PKI Status for Collection* report has been updated to provide clarity on the meaning of "Total Active Certificates".
- **Agent, Orchestrators, and Orchestrator Management**
  - The Orchestrator Details dialog has been updated to show more information about the orchestrator:
    - Legacy Thumbprint
    - Current Thumbprint
    - Last Thumbprint Used
    - Last Register Status
    - Certificate Rotation Status

- The Job History now shows the time the job completed.
- The default value for the *Registration Handler Timeout (seconds)* application setting has been extended to 90 seconds for new implementations only. Keyfactor recommends any existing customers using or planning to use custom registration handlers consider extending this timeout to at least 60 seconds.
- SSL scan job parts are now grabbed more deterministically to help keep the job assignments more predictable. For more information, see SSL Network Operations on page 420 in the *Keyfactor Command Reference Guide*.
- The SSL Scan Now option now allows you to select whether to start a discovery job, a monitoring job, or both (see Initiating a Manual Scan on page 430 in the *Keyfactor Command Reference Guide*).
- The Keyfactor Universal Orchestrator now does CRL checking when contacting Keyfactor Command over an encrypted channel (when you configure the orchestrator with a URL referencing https) both when certificate authentication is used and when basic authentication is used. Previously this was only done when certificate authentication was used. If you attempt to connect your orchestrator using SSL and do not have a valid CRL available to the orchestrator, you will get an error message similar to the following:

  ```
  The remote certificate is invalid because of errors in the certificate chain:
  RevocationStatusUnknown, OfflineRevocation
  ```

  For troubleshooting information, see Troubleshooting on page 2444 in the *Keyfactor Orchestrators Installation and Configuration Guide*.

- **Reenrollment**

  A certificate authority and template can now be specified when scheduling a reenrollment job.

- **Certificate Metadata**
  - A certificate metadata field now cannot be deleted if it is in use in a certificate collection definition.
  - When creating a new certificate metadata type, different fields will be displayed depending on the value selected in the Data Type dropdown field. For more information, see Adding or Modifying a Metadata Field on page 613 in the *Keyfactor Command Reference Guide*.
- **Security Identities and Roles**
  - A search bar has been added to search for the collections and containers in the security roles dialog.
  - Improvements were made to performance when loading a large number of security roles in the portal.
  - When copying a security role, a new disclaimer will appear to advise the user that copying a security role will also assign the new role to all the same security identities as the target role.
  - The security roles dialog has been updated to be a tabbed dialog box.
- **UI Changes**
  - Some edit dialogs have been changed to use sliding panels to accommodate two different views within the same page rather than pop up windows.
  - Added scroll bars to the certificate details pop ups.
  - Added the ability to copy data from grid information (e.g. SSL location information when expanding the certificate locations). Information in a grid field can be **copied** to the clipboard by highlighting text in a grid field and clicking **Ctrl+C**.

- Performance improvements have been made in loading large data sets in the Management Portal results grids.

- **System Alerts**

  The alerts that are displayed in the UI for notification of things like failed orchestrator jobs have been renamed "System Alerts" for clarity.

- **Logging**
  - The Keyfactor API and Orchestrator API logs on the Keyfactor Command server and the log for the Keyfactor Universal Orchestrator include a correlation ID that helps to identify log messages that originated from the same request. The correlation ID is a randomly generated GUID that often appears just after the date in the log entry and is the same for all log messages for the given request until the request completes.
  - Lowered the logging level for the user's authentication from Info to Trace to avoid cluttering log files.

- **Mac Auto-Enrollment**

  The Mac auto-enrollment process now identifies all the CAs that have the auto-enrollment template(s) available for enrollment and makes a determination as to whether the enrolling user has permissions to enroll on a CA and whether that CA is online before submitting a request to the CA. Previously, a CA was selected randomly among the CAs that had the template(s) available without regard to the user's permissions on the CA or the availability of the CA.

- **Auditing**

  Orchestrator reset, approval, disapproval will now properly audit under the new 'Orchestrator' category and their respective operation.

- **Installation**
  - On installation, Keyfactor Command creates an initial record in the DatabaseUpgradeLog table that indicates the exact version of Keyfactor Command that created the database. This can be helpful for troubleshooting.
  - If you are upgrading from an older version of Keyfactor Command the installation directory changed, as of Keyfactor Command v9, to C:\Program Files\Keyfactor. Move any scripts or files that are held in the old directory structure to the new location.

- **Policy Modules**

  The policy modules have been migrated to leverage .NET Core.

- **Custom Registration Handlers**

  A custom registration handler can now be designed to enroll against a specific certificate authority and template combination. The registration handler chooses which combination to use. If no combination is requested by the registration handler, then the certificate authority and template from the application settings are used. For more information, see Register a Client Certificate Renewal Extension on page 2406 in the *Keyfactor Orchestrators Installation and Configuration Guide*.

- **Application-Level Encryption Certificate Thumbprint**

The reference thumbprint for the application-level encryption certificate, if configured, is now stored in the registry on the Keyfactor Command server(s) instead of the SQL database to provide a further level of separation from SQL.

Fixes

- **Keyfactor Command**
  - Revocation Monitoring Dashboard panel no longer stalls as perpetually "Loading" for OCSP endpoints.
  - Certificate subjects for PFX enrollment via the legacy API have been fixed so they can be formatted according to the API.CertEnroll.Pkcs12CertificateSubjectFormat app setting.
  - Fixed an issue when parsing the CSR so that CSRs containing IP or Email SANs no longer cause excess warnings in CA syncs, and IP and Email SANs show up in the pending request details.
  - Fixed an issue where synching external certificates would cause an "object reference not set to an instance of an object" error.
  - Fixed an issue with revocation monitoring alerts reporting time in the local time zone instead of UTC. Emails now have the time in UTC. The time is explicitly labeled UTC.
  - Fixed an issue where special characters like apostrophes would appear HTML-encoded in the collection name.
  - Fixed an issue in certificate enrollment where SANs for IPv4 and IPv6 addresses were not being validated properly.
  - Fixed an issue where an untrusted certificate chain would prevent the certificate details dialog from opening. An error will still occur if a certificate chain is attempted to be downloaded and the chain build fails, but will not prevent the dialog from opening.
  - Fixed an issue where the Identity Audit table wasn't populating from the Certificate Search page.
  - Fixed an issue where unscheduling an orchestrator management job failed to cancel the previously staged job.
  - Fixed an issue in enrollment where the subject incorrectly added an extra quotation mark when the subject format default was set in certain ways.
  - Fixed an issue where SQL would timeout when deleting over 1,000 certificates from the Keyfactor Command Management Portal.
  - Fixed an issue where the gateway configured to run as a domain service account and running on the same server as Keyfactor Command caused RPC errors.
  - Fixed an issue where the gateway configured to run as a domain service account caused RPC errors.
  - Lowered the logging level for the user's authentication from Info to Trace to avoid cluttering log files.
  - Fixed an issue where PEM files with headers could not convert to DER with BouncyCastle 1.9.0 and Keyfactor.PKI.dll v4.x.
  - Fixed an issue for certificate store types with the *Advanced>Supports Custom Alias* setting set to **Forbidden**, so that the custom alias should only show on the Add to Certificate Store page when the **Overwrite** checkbox is checked.

- Fixed an issue where using *Delete All* on the Certificate Search page would not delete revoked and expired certificates.
- Fixed an issue in the *Issued Certificates Per Certificate Authority* report that was caused by having templates with the same name in separate forests.
- Fixed an issue with certificate store inventories where a certificate store that had completed an inventory scheduled for an interval would fail if it then was scheduled to run immediately.

- **Keyfactor Agents and Orchestrators**
  - Fixed an issue so that CRLs are now checked regardless of the authentication method being used by the orchestrator.
  - Fixed an issue where permissions were not being set correctly on the appsettings.json and orchestratorsettings.json file that prevented the files being read or updated if the service was running as the Network Service.
  - Fixed an issue where a misconfigured orchestrator using certificate authentication would renew certificate multiple times.
  - Fixed an issue where an orchestrator's registration session was still allowed even when denied by a registration handler and added an auditing event for the orchestrator session registration.

Deprecation

- **Windows Server 2016**

  As of Keyfactor Command version 10.0, Windows Server 2016 is no longer supported.

- **Deprecated Certificate Search Fields**

  The *KeyfactorRequestId*, *RequestResolutionDate*, and *CARequestId* certificate search fields parsers are deprecated due to native EJBCA support in Keyfactor Command as of v10. Any certificate collections using them must be changed before upgrading to v10+.

- **Archive Key on Templates**

  As of Keyfactor Command v10 we no longer support enrolling for certificates that have the archive key option turned on in the template to enable the certificate to store the private key for the certificate in the CA. Attempting to enroll using a template that has this option turned on will result in the following error: *"The certificate request failed with the reason 'The request is missing a required private key for archival by the server."*

- **CA Policy module v7.0**

  You will need to upgrade the CA Policy module to v7.1 before running the Keyfactor Command 10.0 upgrade.

- **Reports**

  The Resolution Date field has been removed from the *Certificate Count by User By Template* report.

Future Changes

- **Microsoft .NET Runtime version 3.1**

  By the end of 2022, Microsoft will no longer be supporting .NET Runtime version 3.1. Currently both Microsoft .NET Runtime version 6.0 (x64) and version 3.1 are supported by Keyfactor.

  If you wish to continue using older versions of the Universal Orchestrator but the newer .NET Runtime, you can update the .NET Runtime version on the orchestrator server without needing to reinstall the orchestrator (see System Requirements on page 2360 in the *Keyfactor Orchestrators Installation and Configuration Guide*).

- **Intune Portal/SCEP Change-over**

  Intune portal change-over will be required for SCEP when the old APIs are shut off by Microsoft's deprecation of ADAL at the end of the year.

Known Issues/Limitations

- When editing a template, changes will be lost without warning if the "Save" button isn't clicked before navigating away. This is slated to be fixed in a future release.
- When editing a template, the checkboxes for the Metadata, Enrollment RegExes, and Enrollment Defaults tabs do not allow for multi-edit. This will be fixed in a future release.
- When copying a security role, the identities associated with the security role will also be copied.
- The Condition Variable field in a step of the workflow builder accepts input values that are not valid. Only "true", "false" and variables that will evaluate to "true" or "false" are supported.
- For most certificate stores, the "Client Machine" is the machine where the store is located, and the "Orchestrator" drop-down selects the orchestrator/agent. However, for the Java Keystore, the "Client Machine" field is actually the agent and there is no orchestrator dropdown. This will be made more clear in a future release.
- When creating a new certificate store type, the "Depends On Other" option may not be available when creating the parameter. The workaround is to save the certificate store type and then use edit to update the parameter.
- Using the browser back button after generating a report creates a nested instance of Keyfactor Command in Firefox.
- Occasionally, removing a widget from the Dashboard causes the dashboard to hang. Refreshing the browser should resolve this issue.
- The -ne operator in certificate search does not return NULL results for Boolean metadata fields. Search for *'Metadata' -ne "False" OR 'Metadata' -eq Null* to get the desired results.
- The *Certificate Count Grouped by Single Metadata Field* report falsely reports no results if using the default metadata value. This will be fixed in a future release.
- The *PKI Status for Collection* report click throughs do not retain the *Include Unknown* certificates option when clicking through to the certificate search results page. This will be fixed in a future release.
- SMTP Sender information isn't correctly saved by the Configuration Wizard. This will be fixed in a future release. It is recommended to check the SMTP Configuration page upon upgrade.
- Alert tests do not show certificate information if there is no recipient configured to receive an email even if **Send Alerts** is not selected. This will be fixed in a future release. The workaround is to add an email recipient

when running the tests.

- Adding multiple enrollment fields at the same time is only saving the last field entered. This will be fixed in a future release. Workaround is to add and save each enrollment field one at a time.
- The *Certificates in Collection* report falsely reports ECC certificates with a certificate state of *Denied* rather than *Active*, revoked certificates with a certificate state of *Active* rather than *Revoked*, and shows a incorrectly shows a revocation reason of *Unspecified* for certificates with an *Active* certificate state. This will be fixed in a future release.

API Endpoint Change Log

The following changes were made to the API endpoints. Please review these carefully if you have implemented any integration using these endpoints.

Table 769: API Change Log

Endpoint	Methods	Action	Notes
/Agents/{id}	GET	Add	
/Agents/Reset	POST	Add	
/AgentBlueprint	GET	Add	
/AgentBlueprint/{id}	GET, DELETE	Add	
/AgentBlueprint/{id}/Jobs	GET	Add	
/AgentBlueprint/{id}/Stores	GET	Add	
/AgentBluePrint/ApplyBlueprint	POST	Add	
/AgentBluePrint/GenerateBluePrint	POST	Add	
/Alerts/Denied	GET, PUT, POST	Add	
/Alerts/Denied/{id}	GET, DELETE	Add	
/Alerts/Expiration	GET, PUT, POST	Add	
/Alerts/Expiration/{id}	GET, DELETE	Add	
/Alerts/Expiration/Schedule	GET, PUT	Add	
/Alerts/Expiration/Test	POST	Add	
/Alerts/Expiration/TestAll	POST	Add	

Endpoint	Methods	Action	Notes
/Alerts/IssuedAlerts	GET, PUT, POST	Add	
/Alerts/IssuedAlerts/{id}	GET, DELETE	Add	
/Alerts/Issued/Schedule	GET, PUT	Add	
/Alerts/KeyRotation	GET, PUT, POST	Add	
/Alerts/KeyRotation/{id}	GET, DELETE	Add	
/Alerts/KeyRotation/Schedule	GET, PUT	Add	
/Alerts/KeyRotation/Test	POST	Add	
/Alerts/KeyRotation/TestAll	POST	Add	
/Alerts/Pending	GET, PUT, POST	Add	
/Alerts/Pending/{id}	GET, DELETE	Add	
/Alerts/Pending/Schedule	GET, PUT	Add	
/Alerts/Pending/Test	POST	Add	
/Alerts/Pending/Test/{id}	POST	Add	
/CertificateAuthorities	GET	Update	Schedules are now included in the results.
/CertificateAuthorities	POST	Update	Ability to turn off schedules, sessions are abandoned properly, and threshold monitoring schedule is included.
/CertificateAuthorities/{id}	PUT	Update	Ability to turn off schedules, sessions are abandoned properly, and threshold monitoring schedule is included.
/CertificateAuthorities/{id}	DELETE	Update	Deletion is now prevented if schedules are associated.

Endpoint	Methods	Action	Notes
/CertificateCollections	POST	Update	Query parameter no longer needed when a valid CopyFromId is provided.
/CertificateCollections/{id}/Permissions	POST	Deprecated	Replaced by /Security/Roles/{id}/Permissions/Collection.
/Certificates/Analyze	POST	Add	
/Certificates/IdentityAudit/{id}	GET	Add	
/CertificateStoreContainers	POST	Add	
/CertificateStoreContainers/{id}	PUT, DELETE	Add	
/CertificateStores/Server	GET, POST, PUT	To Be Deprecated	Server usernames, server passwords, and the UseSSL flag are managed by the /CertificateStores API endpoints directly as JobProperties using the Properties parameter, replacing the deprecated /CertificateStores/Server API endpoints.
/CertificateStores	GET, POST, PUT	Updated	Server usernames, server passwords, and the UseSSL flag are managed by the /CertificateStores API endpoints directly as JobProperties using the Properties parameter, replacing the deprecated /CertificateStores/Server API endpoints.
/Enrollment/PFX (v2)	POST	Add	
/Enrollment/Settings/{id}	GET	Add	
/JobTypes/Custom	POST	Update	DefaultValue property is no longer required, validation is now performed on the JobTypeFields/DefaultValue property, validation prevents names containing spaces.
/JobTypes/Custom/{id}	DELETE	Update	Includes validation so that deletion is prevented if at least one associated approved orchestrator implements the capability.

Endpoint	Methods	Action	Notes
/MacEnrollment	GET, PUT	Add	
/Monitoring/Revocation	GET, POST	Update	Renamed from /Workflow/RevocationMonitoring
/Monitoring/Revocation/{id}	GET, PUT, DELETE	Update	Renamed from /Workflow/RevocationMonitoring/{id}
/Monitoring/Revocation/Test	POST	Add	
/Monitoring/Revocation/TestAll	POST	Add	
/Orchestrators/JobHistory	GET	Update	Added JobId field.
/Orchestrators/ScheduledJobs	GET	Add	
/OrchestratorJobs/Reschedule	POST	Add	
/OrchestratorJobs/Unschedule	POST	Add	
/OrchestratorJobs/Acknowledge	POST	Add	
/Security/Identities/{id}	GET	Add	
/Security/Roles/{id}/Identities	GET, POST	Add	
/Security/Roles/{id}/Containers	GET, POST	Add	
/Security/Roles/{id}/Copy	POST	Add	
/Security/Roles/{id}/Permissions	GET	Add	
/Security/Roles/{id}/Permissions/Global	GET, POST, PUT	Add	
/Security/Roles/{id}/Permissions/Collections	GET, POST, PUT	Add	Replaced the /CertificateCollections/{id}/Permissions endpoint functionality.
/Security/Roles/{id}/Permissions/Containers	GET, POST, PUT	Add	Returns only containers that have a permission set for the selected security role.
/SMTP	GET, PUT	Add	

Endpoint	Methods	Action	Notes
/SMTP/Test	POST	Add	
/Templates	GET, PUT	Update	Includes template-specific policy information.
/Templates/{id}	GET	Update	Includes template defaults.
/Templates/Settings	GET, PUT	Update	Includes global template policies.
/Template/SubjectParts	GET	Add	
/Templates/Global/Settings	GET, PUT	Add	
/Templates/Import	POST	Add	
/Workflow/Certificates/Pending	GET	Update	Now supports query fields of Requester and RequestType.
/Workflow/Definitions/Steps/{extensionName}	GET	Add	
/Workflow/Definitions/{definitionId}	GET, PUT, DELETE	Add	
/Workflow/Definitions	GET, POST	Add	
/Workflow/Definitions/Steps	GET	Add	
/Workflow/Definitions/Types	GET	Add	
/Workflow/Definitions/{definitionId}/Steps	PUT	Add	
/Workflow/Definitions/{definitionId}/Publish	POST	Add	
/Workflow/Instances/{instanceId}	GET, DELETE	Add	
/Workflow/Instances	GET	Add	
/Workflow/Instances/My	GET	Add	
/Workflow/Instances/AssignedToMe	GET	Add	
/Workflow/Instances/{instanceId}/Stop	POST	Add	

Endpoint	Methods	Action	Notes
/Workflow/Instances/{instanceId}/Signals	POST	Add	
/Workflow/Instances/{instanceId}/Restart	POST	Add	

6.1.1 Incremental Release 10.1 Notes

November 2022

Note: Keyfactor Command 10.1 is a minor release with incremental fixes and updates following the Keyfactor Command 10 major release. For more details on new features, improvements, and known limitations in Keyfactor Command 10.0, please review the Major Release 10.0 Notes on page 2490.

Tip: Keyfactor recommends that you check the Keyfactor GitHub Site (https://keyfactor.github.io/integrations-catalog/) with each release that you install to check if you will need to download the updated orchestrators to work with that version of Keyfactor Command.

Changes and Improvements

- **Keyfactor Universal Orchestrator Supports gMSA**

  The Keyfactor Universal Orchestrator now supports running its service as a group managed service account (gMSA).

- **SSL Discovery and Monitoring Jobs have Reset Scan Option**

  A new Reset Scan option has been added for SSL discovery and monitoring jobs that allows to you recover from an SSL job that appears to be stuck or crashed.

Updates and Fixes

- Update: All Keyfactor Command (timer) service jobs have consistent start and stop log messages in both the file and Windows Event Viewer.
- Update: A PAM provider can be used directly by the Keyfactor Universal Orchestrator, such that the server does not retrieve, and does not have access to, the credential.
- Update: Ed448 and Ed25519 keys are now supported for certificate enrollment, policy, import and search.
- Update: Improved support for the Keyfactor Command (timer) service—including a job locking mechanism—in High-Availability implementations.
- Fix: GET /SSL is returning duplicate info in some instances with endpoints sharing a common chain.
- Fix: Certificate store Discovery jobs could not be executed.

- Fix: AnyGateway was declaring all requests as new instead of renew or reissue.
- Fix: The SMTP Sender Account was not populated during the installation and configuration process.
- Fix: SSL discovery scan job errors for entries with a null display name.

Policy Module Updates

- Migrated the Policy Modules to .NET Core 6.
- Updated the Policy Module to create a Windows Event Log entry when the current license is within 60 days of expiration.
- Updated the Policy Module installer to include the EnterpriseLite, SubjectFormat and SCEPRequester modules.
- Updated the Policy Handler Configuration so that changes no longer require the ADCS service to be restarted.

API Endpoint Change Log

The following changes were made to the API endpoints. Please review these carefully if you have implemented any integration using these endpoints.

Table 770: API Change Log

Endpoint	Methods	Action	Notes
/Templates	PUT, GET	Update	Ed448 and Ed25519 keys are now supported for certificate enrollment, policy, import and search.
/Templates/{id}	GET	Update	Ed448 and Ed25519 keys are now supported for certificate enrollment, policy, import and search.
/Templates/Settings	PUT, GET	Update	Ed448 and Ed25519 keys are now supported for certificate enrollment, policy, import and search.

6.1.2 Incremental Release 10.2 Notes

January 2023

Note: Keyfactor Command 10.2 is a minor release with incremental fixes and updates following the Keyfactor Command 10 major release. For more details on new features, improvements, and known limitations in Keyfactor Command 10.0, please review the Major Release 10.0 Notes on page 2490.

Tip: Keyfactor recommends that you check the Keyfactor GitHub Site (https://keyfactor.github.io/integrations-catalog/) with each release that you install to check if you will need to download the updated orchestrators to work with that version of Keyfactor Command.

Changes and Improvements

- **Keyfactor Command (formerly, Timer) Service now runs in an HA environment.**

  The Keyfactor Command (formerly, Timer) service can be installed on every server that Keyfactor Command is installed on. This will allow the service to check out jobs via a locking mechanism which will enforce that any jobs are running on only one service at a time. There is a new *CMSTimerService.exe.config* timeout setting for the service locking mechanism `<add key="Keyfactor.TimerJobs.LockTimeout" value="5000" />` which is the lock timeout. It's the number of ms Keyfactor Command will wait to acquire a lock. By default Keyfactor Command will attempt to get a lock for 5 secs and if unsuccessful, an error will be thrown.

- **Workflow Definitions can be Created via Copy**

  A new option is available on the workflow definitions page that allows you to create a new workflow definition by copying an existing workflow definition. When you create a new workflow definition by copying an existing one, the word "copy" will be appended to the end of the definition name and the workflow key (template) will be cleared. Other data from the copied workflow will be retained.

- **Workflow Step Type Windows Enrollment Gateway - Populate from AD**

  A new workflow step type has been added to support enrollment requests from the Keyfactor Windows Enrollment Gateway using client-side templates configured with the subject as *Build from this Active Directory information*. This workflow step type allows the requests to be completed in Keyfactor Command using an EJBCA template that is not configured to build the subject from Active Directory using the Active Directory information (subject, SANs, and/or SID) supplied in the request from the client.

Updates and Fixes

- Update: The maximum number of characters allowed in a certificate store path has been increased from 256 to 722.
- Update: Users now receive a warning if they attempt to use the Back button in a certificate template after making changes without saving.
- Update: Workflow steps of type Email and Require Approval now go to a failed state if an error occurs in sending an email.
- Fix: An issue encountered with upgrading larger databases in v10.1 is fixed in the current v10.2 release which addressed this specific portion of the database upgrade, and should allow upgrade without this issue.
- Fix: Agent Application Settings: An agent will not attempt to retry a job when this setting is set to `0`.
- Fix: Certificate stores of a type that required a server but did not require authentication to access that server could not be saved using the "No Value" options for the server username and password.
- Fix: A base-64-encoded PEM certificate added to a PEM certificate store using the Certificates -> Add Certificate feature was not being correctly formatted for the store.
- Fix: If multiple template enrollment fields were added at the same time before saving, only the most recently added one was saved.
- Fix: The PKI Status for Collection report drill-downs did not include unknown certificates when the "Include Unknown" box was checked. The "Include Unknown" box also worked inconsistently.

- Fix: Custom orchestrators with a status of Disapproved changed to a status of New when their capabilities were changed. Only orchestrators with a status of Active should change to a status of new when their capabilities are changed.
- Fix: Certificate templates with a key size of Ed448 were imported and assigned a key type of 456.
- Fix: On an attempt to edit the parameters of a built-in report with a parameter of type RelativeDate, an error message appeared indicating "A saved parameter with type 'RelativeDate' is invalid with a value of 'false'" and the user was not allowed to edit the parameters.
- Fix: Chain not being passed in Management Add Job.
- Fix: Certificates cannot be queried by KeyfactorRequestId.

Known Issues

- CSR enrollment fails against a standalone CA. This will be fixed in a future incremental release. Customers using CSR enrollment and standalone CAs should wait to upgrade.

API Endpoint Change Log

The following changes were made to the API endpoints. Please review these carefully if you have implemented any integration using these endpoints.

Table 771: API Change Log

Endpoint	Methods	Action	Notes
/Security/My	GET	Add	Returns all the security roles and global permissions for the requesting user.
/Enrollment/CSR	POST	Update	The workflow instance ID has been added to the response.
/Enrollment/CSR	POST	Update	A new PrivateKey input field has been added to support private key retention on CSR enrollment.
/Enrollment/PFX	POST	Update	The workflow instance ID has been added to the response.
/Certificates/Analyze	POST	Update	The endpoint requires Global Certificates-Read or Certificates-Import permissions.

6.1.3 Incremental Release 10.3 Notes

March 2023

Note: Keyfactor Command 10.3 is a minor release with incremental fixes and updates following the Keyfactor Command 10 major release. For more details on new features, improvements, and known limitations in Keyfactor Command 10.0, please review the Major Release 10.0 Notes on page 2490.

Tip: Keyfactor recommends that you check the Keyfactor GitHub Site (https://keyfactor.github.io/integrations-catalog/) with each release that you install to check if you will need to download the updated orchestrators to work with that version of Keyfactor Command.

Changes and Improvements

- The new **CertStoreContainer** certificate search field shows certificates in a certificate store that is included in the certificate store container specified by the search criteria.
- The Keyfactor Bash Orchestrator added additional support for using an SSSD user store (e.g. Active Directory) on requests to create logons and distribute key information, allowing keys to be managed for domain users. Domain users can be managed with or without preexisting home directories.
- Added the ability to use any symbols when creating a new SSH logon. This is required in order to facilitate creating a logon for an AD user using SSSD.
- The Universal Orchestrator now communicates with IIS certificate stores over TCP port 445 rather then using WinRM and default ports 5985/5986.
- The BASH Orchestrator now returns improved warning messages on the Job History page. See SSH-Bash Orchestrator Job History Warning Resolution on page 660.

Updates and Fixes

- Update: The Keyfactor Bash Orchestrator now adds the command *restorecon* to the list of commands the orchestrator service account is allowed to execute via sudo on servers running SELinux.
- Update: The Keyfactor Bash Orchestrator now trims Windows line breaks from JSON payloads on send and receive and ignores any data in the authorized_keys file that is not a key (e.g. a comment).
- Update: An application setting—*Enable Legacy Encryption*—has been added to enable/disable the use of legacy encryption methods in PFX enrollment. When the value is set to true, the historical algorithm set (3DES/SHA1/RC2) is used for PFX enrollments. When the value is set to false, the newer algorithm set provided by Windows (AES256/SHA256/AES256) is used instead. The default is *false*.
- Update: A script has been added to allow the Keyfactor CA Policy Module to be upgraded from versions prior to 10.0 and retain existing configuration.
- Fix: EJBCA certificates with a leading zero in the serial number could not be revoked; an attempt to do so generated an error.
- Fix: EJBCA CA Config will give a notification if the certificate you selected doesn't meet requirements, and indicate exactly what the requirements are and what your certificate is lacking.
- Fix: The GET /SSL API endpoint was returning duplicate records.

- Fix: The DELETE /Workflow/Defintions/{id} API endpoint was returning an error if the workflow contained steps.
- Fix: Expiration alert tests displayed a blank dialog if the alert was configured with no recipients.
- Fix: The Keyfactor Bash Orchestrator install failed when the service account was provided an extremely long password.

Known Issues

- The dashboard will throw a secure key error if you let the dashboard sit idle for around 20 minutes. The temporary work-around is to refresh the page. It will be investigated in 11 for a possible fix.
- Because a "+" (plus sign) in a URL can represent either a space or a "+", Keyfactor Command has chosen to read "+" as a space. For CRL URLs that require a "+" (plus sign), rather than a space, replace plus signs in your CRL's URL with "%2B". Only replace the plus signs you don't wish to be treated as a space.
- A user without *Global Certificates - Read* and *Global Certificates – Import* will see a permission error dialog when attempting to view an enrollment workflow instance that has **completed**. The only impact of this error is that it will result in the certificate's information not being parsed in the *Instance Review dialog*. Users should not need these permissions to view their completed workflow instances, and so should not be seeing this error. This will be fixed in the next Keyfactor Command release. The raw data is still present. As a workaround, if a user wants to see the parsed data for that certificate, they would have to use the **KeyfactorId** (found on the workflow instance) in the certificate search page using the **CertId**.

API Endpoint Change Log

No API endpoint changes were made in this release.

6.2 Major Release 9.0 Notes

August 2021

Release Highlights

We're thrilled to announce Keyfactor Command 9.0, which includes several new features and updates to improve the user experience, deployment flexibility, and risk awareness.

Highlights from the Keyfactor Command 9.0 release are listed here. More details are available in the New Features, and Updates and Improvements sections further down.

Important: There have been several UI updates to the navigation menu, drop-downs, and application settings. Thoroughly review these changes in the New Features section.

UI Enhancements

- **What problem does it solve?**

  The Keyfactor Command interface should be easy to navigate and use.

- **How does it work?**

  As we continue to improve the Keyfactor Command interface, we've added updates to the navigation menu, application settings, and dialogues, as well as an updated color scheme.

- **What's the benefit?**

  Ease of Use: The Keyfactor Command interface is more intuitive for new and experienced users alike.

New Risk Header

- **What problem does it solve?**

  PKI administrators and application owners want to easily identify risks and upcoming expirations for the certificates they have access to.

- **How does it work?**

  A new fixed header above the dashboard displays expiring, weak, and revoked certificates for an at-a-glance view of risks.

- **What's the benefit?**

  Risk Mitigation: Enables administrators to quickly identify the state of their certificates.

New Universal Orchestrator

- **What problem does it solve?**

  The current Windows Orchestrator is only able to run on Windows systems.

- **How does it work?**

  The new Keyfactor Universal Orchestrator runs on .NET Core 3.1, which allows it to be installed on servers/instances running either Linux or Windows.

- **What's the benefit?**

  Flexibility: Enables customers to deploy orchestrators in cross-platform environments.

New Remote CA Gateway

- **What problem does it solve?**

  Certain customers are unable to use Keyfactor PKI as-a-Service due to security or regulatory requirements, but they'd still like to leverage a SaaS-based solution for certificate management.

- **How does it work?**

  The new Remote CA Gateway securely connects on-premise private PKI – Microsoft ADCS or PrimeKey EJBCA – to the Keyfactor Cloud. This allows customers to leverage Keyfactor Command as a Service (SaaS) while keeping their PKI within their datacenter.

- **What's the benefit?**

Cloud: On-premise customers now have more options to deploy Keyfactor in a SaaS model – while keeping their PKI in-house, if required.

Support for TLS 1.3

- **What problem does it solve?**

  Before Keyfactor Command 9.0, Keyfactor Command did not support SSL/TLS scanning on endpoints using TLS 1.3.

- **How does it work?**

  The Keyfactor Universal Orchestrator supports SSL/TLS scanning on endpoints using TLS 1.3.

- **What's the benefit?**

  Increased Visibility: Organizations will have improved visibility over certificates.

Template-Level Metadata

- **What problem does it solve?**

  Before Keyfactor Command 9.0, certificate metadata could only be applied system wide.

- **How does it work?**

  Now administrators can apply metadata on a per-template basis, which will override system-wide settings for that specific template.

- **What's the benefit?**

  Control: This gives administrators more granular control for metadata in certificate enrollment.

Ecosystem Updates

While separate from the Keyfactor Command 9.0 release, we've recently introduced several new integrations in GitHub to support more certificate authorities, applications, and services.

These include:

- Google Cloud CA Service: A new AnyCA Gateway implementation supports discovery and automation of certificates issued by Certificate Authority Service (CAS).
- Google Cloud IoT Core: The IoT Issued Alert Handler publishes device certificates to various cloud providers, including Google Cloud, Azure, and AWS.
- GoDaddy: The GoDaddy CA Gateway enables enrollment, renewal, re-issuance, and revocation of certificates via Keyfactor Command.
- Sectigo Certificate Manager: The Sectigo CA Gateway enables full lifecycle management of certificate issued by Sectigo via Keyfactor Command.
- Kubernetes: A proxy signs certificate-signing requests (CSRs) through Keyfactor via the Kubernetes CSR signer API.
- Azure Key Vault: Allows customers to inventory and manage certificates within their Azure Key Vault instances.

More information and developer resources can be found in the Keyfactor GitHub.

New Features

UI Enhancements

Tip: We encourage existing Keyfactor Command customers to watch the Keyfactor Command 9.0 UI Walk-through demo and read through the detailed UI changes listed below before upgrading to Keyfactor Command 9.

Keyfactor Command 9.0 includes significant updates to the UI, as well as several changes to the main navigation menu and drop-downs with a focus on improved usability. Please continue reading to review and understand these changes.

Previously, the navigation menu looked like the example below:

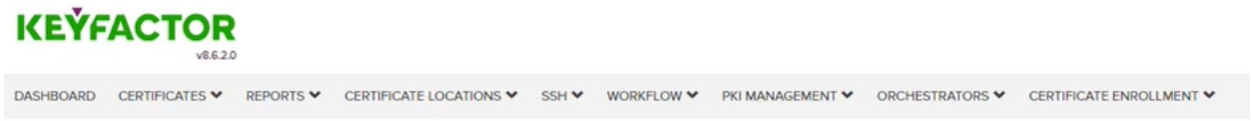

Figure 575: Example Navigation Menu Before Upgrade to 9.0

In Keyfactor Command 9.0, the navigation menu is more concise and user-centric:

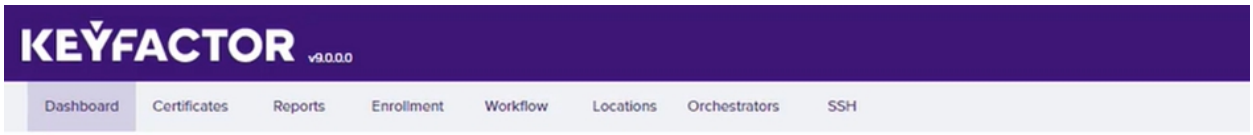

Figure 576: Example Navigation Menu After Upgrade to 9.0

Certificates drop-down

- Add Certificate: The Add Certificate selection is now located in the Certificates tab. Previously, it was accessed via the Certificate Locations tab.

Enrollment drop-down

- Certificate Requests: This option is now found in the new Enrollment tab, rather than the Workflow tab.

Workflow drop-down

- Revocation Monitoring: This option is now located in the Workflow tab. Previously, it was located in the PKI Management tab.
- Expiration: This selection was previously named Expiration Alerts.
- Pending Request: This selection was previously named Pending Request Alerts.
- Issued Request: This selection was previously named Issued Request Alerts.
- Denied Request: This selection was previously named Denied Request Alerts.
- Key Rotation: This selection was previously named Key Rotation Alerts.

Locations drop-down

- Certificate Stores: You will now access the Certificate Stores selection from the new Locations tab. Previously, it was accessed via the Certificate Locations tab.
- Certificate Authorities and Certificate Templates: These menu options are now found in the new Locations. Previously, they were located in the PKI Management tab.
- SSL Discovery: This selection is now located in the Locations tab. It was previously located in the Certificate Locations drop-down.

System Settings menu

- Certificate Store Types: You will now access the Certificate Store Types from the System Settings at the top-right of the screen. It was previously under Certificate Locations.

Certificate Search

- There is a new "ends with" operator. For example:

  ```
  CN -endswith "keyexample.com"
  ```

- A new advanced search option has been added of %ME-AN%. This does a search for account name without domain. For example, the following search in certificate search:

  ```
  NetBIOSRequester -contains "%ME-AN%"
  ```

  Would return certificates requested by the current user as KEYEXAMPLE\jsmith and KEYOTHER\jsmith (assuming the current user is logged in with username jsmith in some domain).

New Risk Header

A "Risk Header" has been added to the Dashboard, which displays relevant information for certificates the user has permissions to. This includes a count of all active certificates, upcoming expirations, expired and revoked certificates, and weak keys (as seen below).

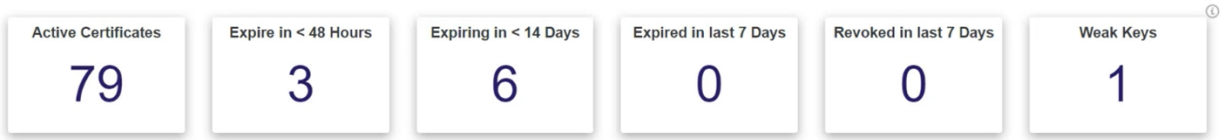

Figure 577: New Risk Header

Note: The new Risk Header is intended to provide an at-a-glance view of key metrics. Unlike items within the dashboard below it, the header cannot be moved or customized.

New Universal Orchestrator

Now available in Keyfactor Command 9.0, the new Keyfactor Universal Orchestrator can perform many of the same functions as the legacy Windows Orchestrator, such as IIS, SSL, FTP and CA management (we will continue to expand its functionality). However, unlike the legacy Windows Orchestrator, the new Keyfactor Universal Orchestrator is able to run on both Windows and Linux servers.

The purpose of orchestrators is to perform SSL scans, manage certificate stores (both Java Key Stores and Windows Certificate Stores), run custom certificate management jobs, inventory CAs, and collect logs to be viewed in the Keyfactor Command Console.

Please review the Deprecation on page 2520 section for more information about the eventual deprecation of the legacy Windows Orchestrator. Refer to the Installing Orchestrators on page 2355 guide for more information on the new Keyfactor Universal Orchestrator.

New Remote CA Gateway

Before Keyfactor Command 9.0, customers had the option to deploy Keyfactor Command on-premise or hosted in the cloud with a fully managed private PKI as a Service (PKIaaS). Now customers have the additional option to keep their PKI on-premise while leveraging Keyfactor Command in the cloud.

The Keyfactor Remote CA Gateway is the connection point between the new Keyfactor Command as-a-Service deployment model (aka Certificate Lifecycle Automation as a Service or CLAaaS) and a customer's on-premise PKI behind their firewall.

The Remote CA Gateway synchronizes in real-time to provide full visibility and governance over the inventory, enrollment, issuance, revocation and renewal of certificates from your on premise CA, requiring just a single, secure API connection on port 443 back to the Keyfactor Command Cloud.

Template-level Metadata

Certificate metadata fields can now be defined on a per-template basis. Before Keyfactor Command 9.0, metadata fields could only be defined as a system-wide setting.

This allows administrators to apply required, hidden or optional settings to a metadata field on a per-template basis so that only certain metadata fields will appear on certain templates.

System-wide settings for metadata fields can be overridden, so customers can choose which fields are displayed, during enrollment for a certificate, based on the template the user selects when enrolling.

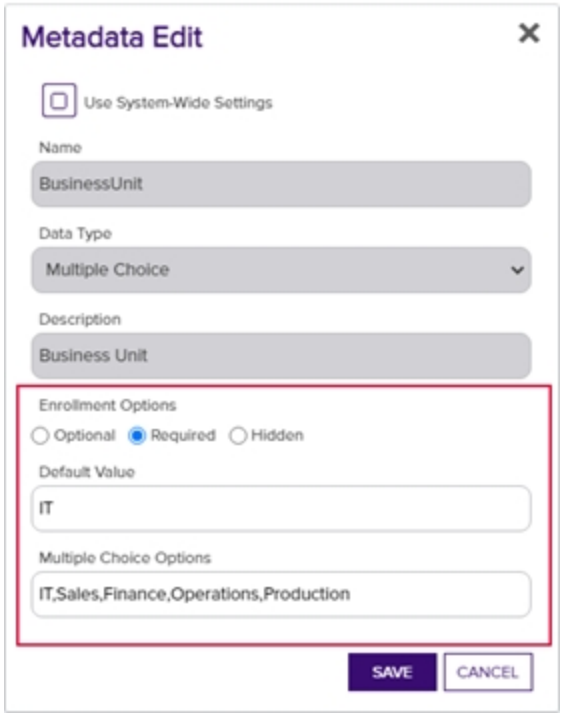

Figure 578: Template Level Metadata

Documentation Structure Updates

Next and Previous buttons have been added to the button row at the top of each page that allow you to navigate through the pages in the documentation in order.

The mini table of contents has been updated to only display by default on pages that contain subpages. This TOC displays—with links—any pages that appear below the current page in the document structure. The TOC button can be used to close and reopen the mini table of contents. The mini table of contents will not display on pages where no subpages are present.

The TOC button now appears when the documents are used in a small browser session (e.g. on a tablet).

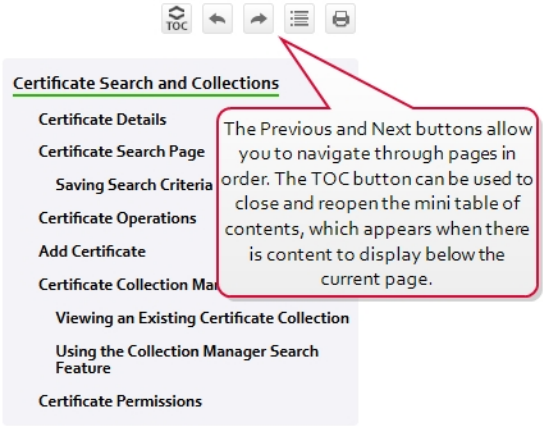

Figure 579: Navigate Forward and Backwards Through Pages

Updates and Improvements

- **Discovery**

  SSL/TLS scanning has been updated to support discovery and monitoring of certificates at endpoints that serve certificates via TLS 1.3. The scan works with the TLS_AES_128_GCM_SHA256 cipher suite. TLS 1.3 connections will also work with SNI.

- **API**

  More API endpoints have been added to do things such as manage security roles, configure certificate store jobs, and manage orchestrators. Please see the Web APIs Reference on page 717 for more details. You can access this and the API Endpoint Utility from the portal via the Help icon.

  Additionally, the need for an API application key and secret has been removed. We now control certificate enrollment on the template level within the portal.

- **Logging**

  The log file default locations have moved from C:\CMS\Logs to C:\Keyfactor\Logs. In addition, the NLog.config files have moved from the C:\Program Files\Common Files location to application subfolders of the installation directory, which is C:\Program Files\Keyfactor\Keyfactor Platform by default. Instead of one large CMS_Log file, there are logs for each individual applications.

  See Editing NLog on page 669 in the *Keyfactor Command Reference Guide* for more information.

  > **Tip:** The API is used in conjunction with the applications and both the API log and the relevant other log (e.g. portal) should be consulted when troubleshooting.

- **Administration**
  - There is now an option in the Application Settings to require users to agree to Subscriber Terms to enroll for a certificate. This setting also allows administrators to provide a link to those terms.
  - CRL Stale Monitoring has been replaced with the ability for customers to define their own definition of "Stale" by generating alerts—and log entries—off the date that the CRL expires, rather than looking at the

Next Publish date.

The main reason for that is that there is, by definition, a race condition between when the new CRL gets created (exactly at the Next Publish time), and when it is copied to the CRL distribution points. Basing alerts off CRL expiration allows customers to tune timeframes based on the way they handle their CRLs.

- **Automation**

  A new constraint has been added to only allow the PowerShell event handlers to run scripts that are located in the path specified in the *Extension Handler Path* in the application settings. By default, this is "C:\Program Files\Keyfactor\Keyfactor Platform\ExtensionLibrary\". Customers should move scripts to this location or a subdirectory of it and test alerts before going into production. See Adding PowerShell Handlers to Alerts on page 196 in *Keyfactor Command Reference Guide* for more information.

- **Certificates**
  - A new field for "Import Date" has been added to the certificate details page to log when the certificate was imported into the Keyfactor Command database.
  - Certificate Validation now shows the tests that are run when you click on a certificate and the results of those tests.
  - SSL/TLS network name is now displayed on the certificate details dialog.
  - Denied certificate requests now show the denial reason.
  - The CSR generation page has been updated to show the Extended Key Usage of the selected template.

- **Certificates**

  Denied certificate requests are now labeled as "Denied/Failed" to align with public CA terminology.

- **Enrollment**

  Email address subject alternative name option has been added to PFX enrollment.

- **Infrastructure**

  Application pool and service accounts are no longer configured with the db_owner role in SQL, but use a new custom role instead.

- **Orchestrator**

  The certificate thumbprint has been added to the failed job message to help identify which certificate was unable to be deployed to an endpoint.

- **Certificate Authorities**

  A new uniqueness constraint has been added to the CertificateAuthorities table. As a result, Keyfactor Command now checks that no CAs share the same logical name and host name combination.

- **Reporting**
  - Added the ability to add a custom logo to scheduled reports.
  - A new report has been added called *Expiration Report by Days* that allows for a number of days to be specified to return a table of the certificates expiring in that timeframe.
  - A column for Reverse DNS has been added to the *Certificates Found at TLS/SSL Endpoints* report.

- **Templates**

RFC 2818 enforcement has moved from the CA to the template level since different templates have different requirements. Standalone CAs still have the RFC 2818 setting on the CA level.

- **Certificates**
  - Fixed an issue where container level permissions were being ignored during enrollment preventing users from being able to add a certificate to a certificate store in that container.
  - Fixed an issue where regular expressions were being applied to empty values when they should not have been.
- **Dashboard**

  Resolved an issue where the dashboard CRL widget failed to load when configured with a high number of CRLs.
- **Email**

  An issue is fixed where the emails sent from the SSL/TLS scans sometimes reported incorrect totals.

Upgrade Prerequisites

- **Keyfactor Orchestrators**

  We encourage customers to use the new Keyfactor Universal Orchestrator moving forward, which requires .NET Core version 3.1. For existing deployments, .NET version 4.7.2 is required for systems running the legacy Windows Orchestrator.
- **SQL Server 2016**

  Support for SQL Server 2016 has been removed in Keyfactor Command 9.0. Customers should upgrade to SQL Server 2016 Cumulative Update 2 or higher before upgrading to Keyfactor Command 9.0.
- **Database Compatibility**

  Customers will also need to ensure the database compatibility is updated to support 2016 or higher. For more information on updating the compatibility level, please see System Requirements on page 2217 in the *Keyfactor Command Server Installation Guide*.

Upgrade Tasks

Pre-Installation

- If you are using the CA Policy module v7.0 on the same server that the Keyfactor Command Management Portal is installed on, you'll need to upgrade the module to v7.1 before running the Keyfactor Command 9.0 upgrade.
- Upgrade to SQL Server 2016 CU12 or higher and adjust the database compatibility level if needed (see above).

Post-Installation

After the upgrade is complete, some settings will need to be reconfigured due to changes in the way the Keyfactor Command Console handles tasks in Keyfactor Command 9.0:

- RFC 2818 enforcement has moved from the CA to the template level since different templates have different requirements. Standalone CAs still have the RFC 2818 setting on the CA level.

- Configure template-level metadata (if desired).
- Move all Event Handler scripts to the ExtensionLibrary folder under theKeyfactor program installation directory.
- Scripted alert handlers will fail to run if not in the path (or a subdirectory of it) specified by the "Extension Handler Path" application setting. By default, this is "C:\Program Files\Keyfactor\Keyfactor Platform\ExtensionLibrary\". Customers should move the scripts to this location and test them before moving to production.
- Update any monitoring or other processes that reference the log files to point to the new log file location.

Tip: We encourage customers to contact their customer success manager to discuss the new features and functionality in Keyfactor Command 9, and to schedule an upgrade.

Deprecation

- **API Applications**

  There is no longer the need to configure an API Application in the portal to allow for API enrollment for a certificate with a particular template. Template enrollment permissions are now controlled within the portal on the template level.

- **Classic API**

  The API calls that were previously in the Classic API (CMSAPI) have now been migrated to the Keyfactor API. Customers should use the Keyfactor API going forward and plan to migrate off the CMSAPI in the near future. Support for the CMSAPI will continue for the near future to allow customers time to migrate.

- **Expiration Renewals**

  Existing expiration renewals with Event Handlers will need to have the URLs updated to point to the Keyfactor API instead of the CMSAPI.

- **Windows Orchestrator**

  We will continue to support the Windows Orchestrator. However, all new integrations and extensions will be delivered via the new Keyfactor Universal Orchestrator. We recommend customers use the Keyfactor Universal Orchestrator moving forward as new integrations become available.

- **Verbosity in API Call**s

  In a future version of Keyfactor Command, the API will return all data regardless of the verbosity level. For backwards compatibility where performance is concerned, verbosity will be honored when loading certificate location data in the certificate query but has been replaced with new flags to include this data for future requests.

- **Active Directory**

  In future releases, the ability to use the Active Directory (AD) password on PFX enrollment will be deprecated as we upgrade to allow authentication methods other than AD.

Known Issues/Limitations

Administration

- Daylight Savings Time (DST) is now shown as the time zone locale for clients using Keyfactor Command, rather than the UTC offset, which is the Microsoft CA default. This causes issues during DST to appear off by an hour, in time zones that do not have DST.
- Microsoft IIS settings to change authentication must be made manually to support the "Use Active Directory Password" application setting for the Keyfactor Command Management Portal.
- When using Basic Authentication, the authentication in Microsoft IIS may need to be configured manually for the KeyfactorAnalysis site.
- Authentication between the KeyfactorPortal, KeyfactorAPI, and KeyfactorAnalysis sites needs to be configured with the same authentication type, SSL, and host name.
- On the template RegEx settings, if you unselect use system-wide and do not enter a new RegEx the system-wide RegEx will still apply. To fix this, enter .* in the RegEx field to accept all values.
- When creating a new certificate store type, the "Depends On Other" option may not be available when creating the parameter. The workaround is to save the certificate store type and then use Edit to update the parameter.

Certificates

- Editing certificate details on a collection for a CA, while an initial sync is running on the CA, will cause inaccurate numbers to display in the Edit All window.
- If a CA is not scheduled to sync under Locations, it will not appear in lists to select for things like inclusion in Dashboards and Reports.
- Syncing an Issuing CA before syncing its parents in the chain causes Keyfactor Command to show the wrong requester for the chain certificates.

Keyfactor Command cannot support a CA in the local forest, with the same NetBIOS name as a CA in a trusted forest.

Infrastructure

- Running large SSL scans can impact Keyfactor Command application performance, if the Windows Agent/Orchestrator performing the scan is installed on the same server as the Keyfactor Command portal.
- If you receive an error when opening the portal that "the underlying connection was closed" please be sure you have the latest Windows Updates installed.

Reporting

- In Windows, drive mapping is done on a per-user basis. If you would like scheduled reports to be saved to a mapped drive, the timer service account needs to have that mapping created for them beforehand.
- Exporting a report to Microsoft Excel can fail with a 401 error in Microsoft Edge. Chrome or Firefox can successfully export to Excel. This problem is being worked on by the reporting engine vendor (Logi Analytics).

- Users configured for Logi Analytics reporting cannot have double quotes in the password field.

API

- The GET/Certificates API endpoint has a known issue where if a collection ID is not supplied the request fails. This will be fixed in an incremental release. The workaround in the meantime is to provide a collection ID of zero.

UI

- Occasionally, the "Please Wait" message will hang. Control + F5 will fix this.

Orchestrator

- There is an issue where the Universal Orchestrator is missing a task category in the Windows Event Log and instead reporting a task category of "(16)". This will be fixed in a future release.
- The new Keyfactor Universal Orchestrator provides much of the same functionality as the legacy Windows Orchestrator (see table below).

Table 772: Keyfactor Universal Orchestrator vs Windows Orchestrator Capabilities

Capabilities	Windows Orchestrator	Universal Orchestrator
IIS Management	✓	✓
CA Synchronization	✓	✓
SSL/TLS Discovery	✓	✓
FTP	✓	✓
F5 (SOAP/REST)	✓	
AWS	✓	
NetScaler	✓	
Fetch Logs (new)		✓

New capabilities will be added to the Keyfactor Universal Orchestrator in a future release as we phase out use of the existing Windows Orchestrator over time.

API Endpoint Change Log

The following changes were made to the API endpoints. Please review these carefully if you have implemented any integration using these endpoints.

Table 773: API Change Log

Endpoint	Method	Action	Notes
/Agents/Approve	POST	Add	
/Agents/Disapprove	POST	Add	
/CertificateCollections	PUT	Add	
/CertificateCollections/Copy	POST	Add	
/Certificates/{id}/History	GET	Add	
/Certificates/{id}/Security	GET	Add	
/Certificates/{id}/Validate	GET	Add	
/Certificates/Locations/{id}	GET	Add	
/Certificates/Metadata/Compare	GET	Add	
/Certificates/Metadata/All	PUT	Add	
/Certificates/RevokeAll	POST	Add	
/CertificateStoreContainers	GET	Add	
/CertificateStoreContainers/{id}	GET	Add	
/CertificateStores/Certificates/Add	POST	Add	
/CertificateStores/Certificates/Remove	POST	Add	
/Enrollment/CSR/Context/My	GET	Add	
/Enrollment/PFX/Context/My	GET	Add	
/JobTypes/Custom	GET, POST, PUT	Add	
/JobTypes/Custom/{id}	GET, DELETE	Add	
/OrchestratorJobs/Custom	POST	Add	
/OrchestratorJobs/JobHistory	GET	Add	

Endpoint	Method	Action	Notes
/OrchestratorJobs/JobStatus/Data	GET	Add	
/Reports	GET, PUT	Add	
/Reports/{id}	GET	Add	
/Reports/{id}/Parameters	GET, PUT	Add	
/Reports/{id}/Schedules	GET, POST, PUT	Add	
/Reports/Custom	GET, POST, PUT	Add	
/Reports/Custom/{id}	GET, DELETE	Add	
/Reports/Schedules/{id}	GET, DELETE	Add	
/Security/Identities	GET, POST	Add	
/Security/Identities/{id}	DELETE	Add	
/Security/Identities/Lookup	GET	Add	
/Security/Roles	GET, POST, PUT	Add	
/Security/Roles/{id}	GET, DELETE	Add	
/SSH/Keys/Unmanaged	DELETE	Add	
/SSH/ServiceAccounts	DELETE	Add	
/SSH/Users/Access	POST	Add	
/SSL/Networks/{id}/Scan	POST	Add	

6.2.1 Incremental Release 9.1 Notes

September 2021

Note: Keyfactor Command 9.1 is a minor release with incremental fixes and updates following the Keyfactor Command 9 major release. For more details on new features, improvements, and known limitations in Keyfactor Command 9.0, please review the Major Release 9.0 Notes on page 2510.

New Features

Custom Certificate Store Parameters

- **What problem does it solve?**

  Provide the ability to associate custom parameters with certificate stores and certificate store entries to associate useful information.

- **How does it work?**

  The certificate store type dialog now provides tabs for entry parameters, in addition to custom fields. These parameters and custom fields can be defined for input during enrollment, storage and management of certificate store inventory. For more information, see Entry Parameters Tab on page 610 in the *Keyfactor Command Reference Guide*.

- **What's the benefit?**

  Flexibility: Allows for further customization around certificate stores which can be dictated by customizable data.

Certificate Store Inventory

- **What problem does it solve?**

  The previous version of certificate store inventory leveraged the certificate search functionality. While this worked, it was not always well-suited for the viewing of certificate store inventory.

- **How does it work?**

  Clicking on the *View Inventory* button with a certificate store selected will now load a dialog with the inventory of the store.

- **What's the benefit?**

  Ease-of-Use: Enables administrators to efficiently review certificate store inventory.

Certificate Store Type Parameters

- **What problem does it solve?**

  The previous certificate store type parameters were defined via a comma-separated list and were not strongly typed.

- **How does it work?**

  A formalized list is available to define parameters explicitly, including type (String, Boolean, Multiple Choice, Secret).

- **What's the benefit?**

  Flexibility: Enables more powerful definition of certificate stores and data-validity checking.

Certificate Store Parameter Reporting

- **What problem does it solve?**

  The current on-boarding of certificate stores requires manual data entry of custom fields and parameters.

- **How does it work?**

  The Keyfactor Command orchestrator framework provides for orchestrators to report certificate store entry parameters.

- **What's the benefit?**

  Flexibility: Enables customers to more easily track new certificate stores and changes to them made out-of-band from Keyfactor Command.

Keyfactor Command Configuration Wizard

The Keyfactor Command server configuration wizard now supports entry of group managed service accounts (gMSA) in the Administrative Users field on the Keyfactor Portal tab.

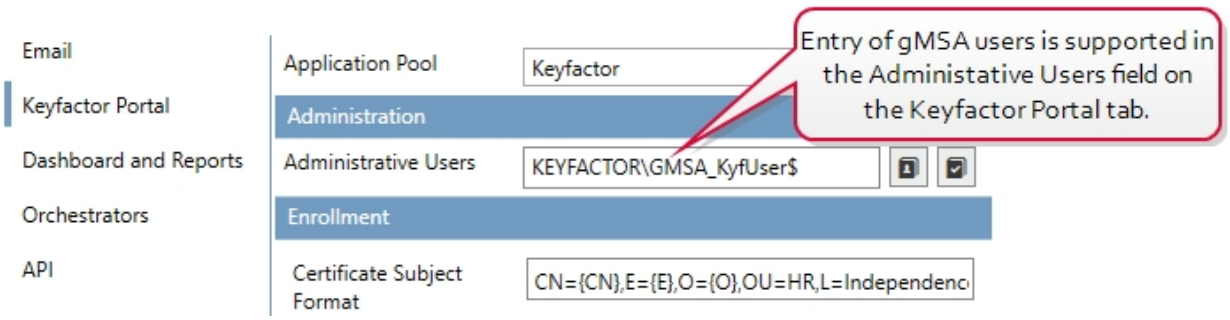

Figure 580: Entry of gMSA Users in the Administrative Users Field

Note: Entry of gMSA users is not supported in the fields that require entry of a password in the configuration wizard (e.g. the service account on the Service tab) at this time. GMSA users cannot be selected using the people picker.

Updates and Improvements

- **Job Completion**

  Job completion handler is now provided the certificate identifier upon renewal so that the handler can perform any related tasks.

- **API Endpoint Deprecation**

  The CertificateCollections/{id}/Permissions endpoint due to an update slated for the Keyfactor Command v10 release and the fact that the endpoint is not updating permissions properly.

- **Permissions Message**

  An incorrect error message was displayed to users without sufficient permissions to a certificate collection.

- **Certificate Store Deletion**

  Fixed an issue in which a Certificate Store cannot be deleted if there is a job staged against it.

- **Pending Alerts**

  Pending alerts were being sent on certificate issuance regardless of the associated template.

- **Certificate Inventory**

  Corrected a permissions problem in which users with only read permissions on a Certificate Store were unable to view inventory of that certificate store.

Known Issues

- **CSR Enrollment**
  In cases where there are duplicate template names in multiple forests, CSR enrollment can sometimes go to the wrong CA. This will be fixed in a future incremental release. Customers with environments with duplicate templates should wait to upgrade.

API Endpoint Change Log

The following changes were made to the API endpoints. Please review these carefully if you have implemented any integration using these endpoints.

Table 774: API Change Log

Endpoint	Methods	Action	Notes
/CertificateStores/{id}/Inventory	GET	Add	
/Enrollment/PFX/Replace	POST	Fix	SuccessfulStores collection now only includes Ids of stores that were successfully processed.
/Enrollment/PFX/Deploy	POST	Update	Now allows for multiple stores of the same type with different parameters.
/CertStoreTypes	POST/PUT	Update	EntryParameters can now be set via these methods.
/CertificateStores/Certificates/Add	POST	Update	Now allows for multiple stores of the same type with different parameters.
/CertificateStores/Certificates/Remove	POST	Update	Now allows for multiple stores of the same type with different parameters.
/CertificateCollections/{id}/Permissions	GET	Deprecate	

6.2.2 Incremental Release 9.2 Notes

October 2021

Note: Keyfactor Command 9.2 is a minor release with incremental fixes and updates following the Keyfactor Command 9 major release. For more details on new features, improvements, and known limitations in Keyfactor Command 9.0, please review the Major Release 9.0 Notes on page 2510.

New Features

UI Support for PAM CA Password Entry

- **What problem does it solve?**

  The API previously supported the entry of certificate authority passwords to be stored within a Privileged Access Management (PAM) instance, but the UI did not implement this functionality.

- **How does it work?**

  The certificate authority editor dialog allows for entry of a password to be stored in a PAM instance.

- **What's the benefit?**

  Flexibility: Allows for multiple ways to securely store and manage certificate authority passwords

Custom Orchestrator Bulk Scheduling

- **What problem does it solve?**

  Custom orchestrator jobs can currently only be scheduled individually.

- **How does it work?**

  An API endpoint (POST OrchestratorJobs/Custom/Bulk) has been created to implement bulk schedules. The job identifiers along with the desired schedule can be provided in a single call.

- **What's the benefit?**

  Ease-of-Use: Enables administrators to easily schedule large batches of custom orchestrator jobs.

Updates and Improvements

- **CA Management with PAM**

  When configuring the *Use Explicit Credentials* option on a CA, you can now choose a PAM provider as the storage location for the credential password or the Keyfactor secrets table.

- **Logi Analytics License**

  A new license for Logi Analytics is required as the previous version is expiring. The 9.2 release includes the license update. Please see Updating Logi Analytics License on the next page for more information.

- **CSR Parsing Containing Spaces**

  CSRs containing spaces can now be parsed successfully during enrollment.

- **Robust SSL Certificate Parsing Error Handling**

  Certificates that fail to be parsed during SSL scanning are now logged but do not cause the entire scan to immediately fail.

- **Robust Alert Failure Error Handling**

  A failure processing an alert no longer prevents processing of subsequent alerts.

- **Hidden Metadata Enrollment Fields**

  Metadata fields which are hidden during the enrollment process are now displayed properly in the resulting certificate details.

- **Collection-based Reports Failing**

  Reports based on collections containing Revocation, Certificate State or Common Name no longer fail.

- **Incorrect CSR Enrollment CA**

  The proper forest certificate authority is used for enrollment when using the API to enroll via CSR.

- **Denied Alerts Template**

  The Denied Certificate Request alerts are once again properly scoped to the selected template. This was a regression from a previous release.

- **Java & C Agent Inventory Error**

  An error was corrected in which an error was thrown if no entry updates were returned during inventory processing.

- **Orchestrator/Agent Re-Enrollment Error**

  Fixed an issue in which an object reference error was thrown during re-enrollment operations.

- **Orchestrator Ceases Processing after Batch Submission**

  Corrected an issue in which the orchestrators would cease processing after submission of a large batch of SSL results.

Updating Logi Analytics License

Logi is a 3rd party BI tool which is used by Keyfactor Command for its dashboard and report features. The license required for Logi is integrated into Keyfactor Command and resides within the product's Logi folder. The license's current term is 3 years with a 7-day grace period after expiration. During that grace period, an alert will appear, and a new license should be used to remediate the issue. Here are two examples:

- License close to expiration:

  

  Figure 581: Keyfactor Logi License Expiration Alert

  Dashboard:

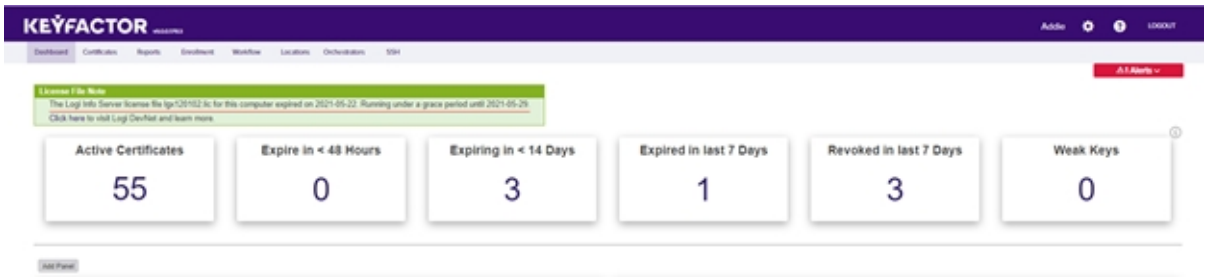

Figure 582: Keyfactor Logi License Expiration Alert on the Dashboard

Report:

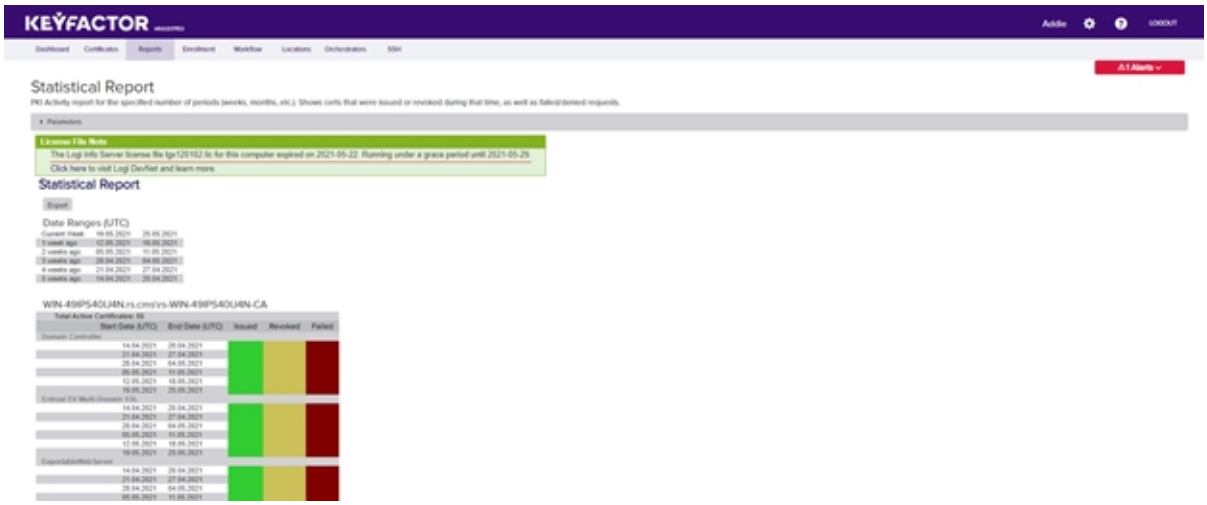

Figure 583: Keyfactor Logi License Expiration Alert on Report

- Expired license:

  The Dashboard and Reporting capability is not available with an error message displayed like the one below.

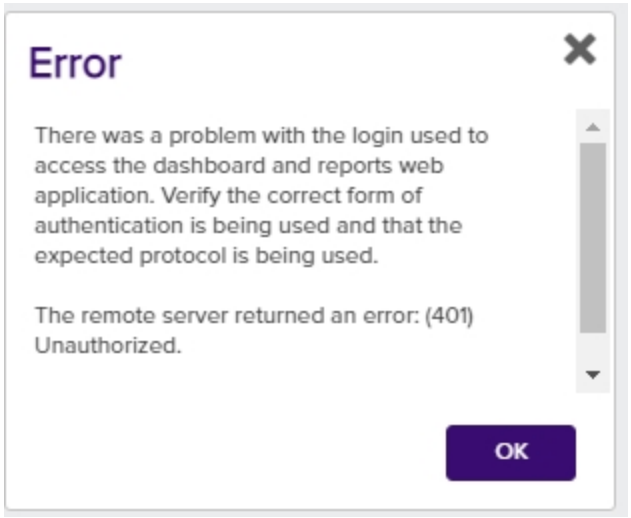

Figure 584: Keyfactor Expired Logi Error Message

Solution

The updated license for Logi is included in release 9.2 and will be installed automatically as part of the upgrade to or fresh installation of this version. If you are not installing Keyfactor Command v9.2, replace the license manually as follows:

1. On your Keyfactor Command server, navigate to the Logi folder in your Keyfactor Command instance. By default, this is:

   C:\Program Files\Keyfactor\KeyfactorPlatform\Logi
   If you are on an earlier version of Keyfactor Command your license file will by default be found in the following directory:

   C:\Program Files\Certified Security Solutions\Certificate Management System\Logi]

2. The license file ends with an extension of *.lic*. Replace the license file with a valid one provided to you by Keyfactor. The license filename cannot be changed and should remain as "lgx120102.lic".

If the license has already expired, once it is replaced with a valid one and the browser is refreshed, the product will work as expected. The alert will no longer appear.

If you upgrade to a version of Keyfactor Command prior to v9.2 after replacing the license file, you will need to manually add the new license file again.

API Endpoint Change Log

The following changes were made to the API endpoints. Please review these carefully if you have implemented any integration using these endpoints.

Table 775: API Change Log

Endpoint	Methods	Action	Notes
/Certificates	GET	Fix	No longer fails if a collection id is not provided.
/OrchestratorJobs/JobHistory	GET	Fix	Request no longer fails for 'Dynamic' job types.
/Reports/Schedules/{id}	DELETE	Fix	Response code is now 200 when the user role does not have *Modify – Report* permission.

6.2.3 Incremental Release 9.3 Notes

November 2021

Note: Keyfactor Command 9.3 is a minor release with incremental fixes and updates following the Keyfactor Command 9 major release. For more details on new features, improvements, and known limitations in Keyfactor Command 9.0, please review the Major Release 9.0 Notes on page 2510.

Updates and Improvements

- **Certificate Search**

  The certificate search functionality has been optimized to increase speed and efficiency, especially with higher numbers of certificates and associated certificate locations. This means certificate searches done in the management portal for large data sets that include certificates found in certificate stores (e.g. 250,000+ certificates each in 5 or more certificate stores) now complete more quickly.

- **Failed Certificate Management Jobs**

  Certificate management jobs that have failed no longer continue to run.

- **PKI Status Report Time Zone**

  Corrected the format of time zones in the PKI Status for Collection Report.

- **Database Encryption Configuration**

  The Configuration Wizard now verifies the selected database encryption certificate has an associated valid private key.

- **SSL Scanning**

  Updates made to the SSL scanning process to be more efficient and eliminate potential process-locking scenarios.

- **Management Portal User Interface**

  Various Management Portal user interface fixes.

- **Management Portal Reports**

  Updates to Management Portal reports to handle upgrade scenarios and other user interface fixes.

API Endpoint Change Log

The following changes were made to the API endpoints. Please review these carefully if you have implemented any integration using these endpoints.

Table 776: API Change Log

Endpoint	Methods	Action	Notes
/JobTypes/Custom	POST	Fix	No longer requires default field values.

6.2.4 Incremental Release 9.4 Notes

December 2021

Note: Keyfactor Command 9.4 is a minor release with incremental fixes and updates following the Keyfactor Command 9 major release. For more details on new features, improvements, and known limitations in Keyfactor Command 9.0, please review the Major Release 9.0 Notes on page 2510.

Updates and Improvements

- Log4j CVE Vulnerability

  Keyfactor has conducted an assessment of the recently-announced CVE for the log4j library (https://-github.com/advisories/GHSA-jfh8-c2jp-5v3q). We have identified that the vast majority of the Keyfactor suite of products are NOT affected. This includes EJBCA, SignServer, the Keyfactor Command platform, Keyfactor Control, and Code Assure.

  The only component that does make use of the log4j library is the Java Agent for Keyfactor Command; for clarity, all other Keyfactor agents and gateways are NOT affected.

  ### Details

  According to the CVE, exploit of the vulnerability requires compelling log4j to log user-controlled input. In the case of the Java agent, there are mitigating factors, such as:

  - The Java agent has an "outbound-only" connection pattern and does not accept inbound network connections of any kind.
  - Users of the Java agent who could control such input are typically Keyfactor administrators.
  - The limited nature of things the Java agent is expected to log.

  From Log4j – Apache Log4j Security Vulnerabilities:

  - Mitigation: This behavior can be mitigated by setting either the system property log4j2.-formatMsgNoLookups or the environment variable LOG4J_FORMAT_MSG_NO_LOOKUPS to true.

  Patch Implementation—The 8.7.2 version of the Java Agent to utilize the patched version of Log4j, and mitigate the vulnerability.

- **Orchestrator Certs**

  Ability for an orchestrator to use a TLS client authentication certificate to map to a Windows identity in IIS and to use a different TLS certificate provided in an HTTP header to identify the orchestrator to Keyfactor Command.

- **External Validation Certificate Requests**

  Certificate requests returning a status of EXTERNAL_VALIDATION are not treated as failures and will be sync'd with appropriate metadata when the certificate is available.

- **Certificate Detail Data Efficiency**

  The certificate details are obtained from the server when needed, and not as part of the initial certificate query. This greatly increases the efficiency and performance of the page.

- **Query Optimization for Large Scale Environments**

  Multiple optimizations have been made to improve management portal query performance, scalability, and stability in large scale environments.

- **Pending Certificates API Endpoint**

  Metadata for certificate requests in a pending state is now available for retrieval via the /Work-flow/Certificates/Pending API endpoints (GET /Workflow/Certificates/{id} and GET /Work-flow/Certificates/Pending).

- **SSL Scanning Chunk Sizes**

Distinct SSL scanning chunk size application settings are now available for discovery and monitoring to allow for greater control over performance tuning.

- **Dashboard Risk Header Clarifications**

  The dashboard Risk Header now contains verbiage to clarify that no filtering exists for renewed certificates in expired query counts.

  In addition, the dashboard Risk Header contains verbiage noting that the certificate counts are global and not limited to only those to which the current user has access.

- **Custom Job Blueprint Duplication**

  An issue was fixed so that a copy operation on a blueprint successfully copies custom jobs.

- **Certificate Count by Template Report**

  An issue was fixed so to properly retain the selected default certificate authority.

- **SSL Quiet Hours Daylight Savings**

  Updates were made to the SSL Quiet Hours to better handle schedules involving Daylight Savings Times.

- **SSL Monitoring Emails**

  SSL Monitoring emails now send the complete and correct data when multiple orchestrators are in simultaneous use.

- **Certificate Detail Before/Not After Dates**

  Certificate details now display the time in addition to the date for Before and Not After dates.

- **SSL Scanning Certificate History**

  A fix was implemented to properly display the history of certificates imported into the system via SSL scanning.

API Endpoint Change Log

The following changes were made to the API endpoints. Please review these carefully if you have implemented any integration using these endpoints.

Table 777: API Change Log

Endpoint	Methods	Action	Notes
/Workflow/Certificates/Pending	GET	Update	Now returns the associated metadata.

6.2.5 Incremental Release 9.5 Notes

January 2022

Note: Keyfactor Command 9.5 is a minor release with incremental fixes and updates following the Keyfactor Command 9 major release. For more details on new features, improvements, and known limitations in Keyfactor Command 9.0, please review the Major Release 9.0 Notes on page 2510.

Updates and Improvements

- **Agents and Orchestrators**

  Several enhancements have been made to the orchestrators:

  - The alias column size has increased to allow for longer alias names.
  - A new setting allows the IIS stores to be accessed using WinRM over SSL (port 5986).
  - The last thumbprint used for client certificate authentication by orchestrators is now tracked and can be returned using the GET /Agents API method.
  - The UI now allows you to see why an orchestrator could not register for a session rather than having to look in the logs.
  - A new API endpoint has been added to request or require that one or more orchestrators enroll for a new client authentication certificate on the orchestrator's next session registration (POST /Agents/SetAuthCertificateReenrollment).
  - A new API endpoint has been added to reset an orchestrator (POST /Agents/{id}/Reset). Updates include removing orchestrator jobs, deleting associated certificate stores, setting the orchestrator status to new, and clearing thumbprint data as below.
  - The orchestrator reset function in the UI and API now clears the orchestrator client authentication certificate thumbprint data to allow the orchestrator to be reconfigured with a new certificate.

- **Management Portal—Reports**

  The "Expiring in less than two weeks" text in the *PKI Status for Collection* report has been updated to change the color scheme to be more readable (white text on a maroon background).

- **API**

  Fixed an issue with the Enrollment/PFX API call not working without specifying a CA. The JobTypes/Custom API call now returns the Job Retry Count.

- **Certificates—Metadata**

  Fixed an issue so that hidden metadata now shows when using "Edit All".

- **Certificate Stores—Scheduling**

  Fixed an issue to now prompt the user to enter schedule values for "Exactly once" and for "Daily" schedules.

- **Certificate Store—Inventory**

  Fixed an issue when viewing the inventory of certificate store that has an alias without a certificate.

- **Installation—Modify/Remove**

  Corrected an issue where the MSI would freeze if trying to modify or uninstall an installation that had been done without any components selected to be installed.

- **Orchestrators and Agents—Custom Job Retry**

  Corrected an issue where custom jobs would not retry if the job complete handlers failed.

- **Alerting—Email Address Format**

  Fixed an issue where the email address validation was not allowing some valid subdomains.

- **Registration Handler—Enrollment**

The registration handler now receives the certificate chain for enrollments performed via the enrollment callback.

- **Management Portal Reports**

  Updates to Management Portal reports to handle upgrade scenarios and other user interface fixes.

API Endpoint Change Log

The following changes were made to the API endpoints. Please review these carefully if you have implemented any integration using these endpoints.

Table 778: API Change Log

Endpoint	Methods	Action	Notes
/Enrollment/PFX	POST	Update	No longer requires a certificate authority name to be provided.

6.2.6 Incremental Release 9.6 Notes

February 2022

Note: Keyfactor Command 9.6 is a minor release with incremental fixes and updates following the Keyfactor Command 9 major release. For more details on new features, improvements, and known limitations in Keyfactor Command 9.0, please review the Major Release 9.0 Notes on page 2510.

Updates and Improvements

- **Configuration Wizard**

  Fixed an issue in which the SQL Server login for the application pool account was not created by the configuration wizard.

- **Azure Database Creation**

  Fixed an issue in which database upgrades fail on Azure SQL for newly created databases.

- **Certificate Store—Scheduling**

  Fixed an issue in which jobs rescheduled for *immediate* would not execute.

- **Command Line Configuration Wizard**

  Fixed an issue in which the console configuration wizard cannot populate Azure SQL databases.

- **Custom Orchestrator Job Blueprint**

  Corrected an issue where a duplicate custom job schedule was created when applying the same blueprint to orchestrator.

- **Expiration Report by Days**

Corrected an issue where the Expiration Report by Days would crash on DD/MM/YYYY formatted dates.

- **Certificate Renewal in Single Store**

  Fixed an issue where a single certificate stored at multiple aliases within the same certificate store was not renewed successfully.

- **CRL Alert Emails**

  Corrected an issue in which a CRL alert email would be sent even if a new CRL was available.

> **Note:** No changes were made to the Keyfactor Universal Orchestrator in this release, as such the 9.5 version of the Universal Orchestrator should still be considered the latest and is fully compatible with the Keyfactor Command 9.6 release.

API Endpoint Change Log

No API endpoint changes were made in this release.

6.2.7 Incremental Release 9.7 Notes

March 2022

> **Note:** Keyfactor Command 9.7 is a minor release with incremental fixes and updates following the Keyfactor Command 9 major release. For more details on new features, improvements, and known limitations in Keyfactor Command 9.0, please review the Major Release 9.0 Notes on page 2510.

Updates and Improvements

- **JavaScript Caching**

  Updated pages not to cache static files, including JavaScript.

  > **Note:** After upgrading to 9.7, the cache will still need to be cleared one final time so that the latest version of the pages get loaded with the updated cache setting.

- **API CA Auto-selection**

  The Keyfactor API will auto-select an enrollment certificate authority if one is not explicitly provided.

- **Certificate Stores**

  Fixed an issue in which a user could assign a certificate store to a container without explicit permissions to that certificate store.

- **Certificate Stores**

  Fixed an issue in which database upgrades fail on Azure SQL for newly created databases.

- **Certificate Stores—Scheduling**

Fixed an issue in which jobs could appear to be scheduled for a certificate store with no available agent.

- **Security Configuration**

  Fixed an issue in which the security roles management page could not be loaded after deletion of an associated Active Directory (AD) group.

- **Metadata String & Integer Fields**

  Corrected an issue where default values could not be set for metadata fields of type string or integer.

- **Certificate Store Deployment**

  Fixed an issue where a certificate cannot be deployed to a certificate store when deploying using a property instead of a certificate store type or Id.

Note: No changes were made to the Keyfactor Universal Orchestrator in this release, as such the 9.5 version of the Universal Orchestrator should still be considered the latest and is fully compatible with the Keyfactor Command 9.7 release.

API Endpoint Change Log

The following changes were made to the API endpoints. Please review these carefully if you have implemented any integration using these endpoints.

Table 779: API Change Log

Endpoint	Methods	Action	Notes
/KeyfactorAPI/License	GET	Add	

6.2.8 Incremental Release 9.8 Notes

April 2022

Note: Keyfactor Command 9.8 is a minor release with incremental fixes and updates following the Keyfactor Command 9 major release. For more details on new features, improvements, and known limitations in Keyfactor Command 9.0, please review the Major Release 9.0 Notes on page 2510.

Updates and Improvements

- **PFX Generation**

  Consolidated PFX generation code so that the PFX files are generated identically from the enrollment and download components.

- **SCEP Intune Integration**

  Keyfactor's Simple Certificate Enrollment Protocol (SCEP) component has been updated to utilize the latest Intune API: Microsoft Authentication Library (MSAL) and Azure AD Graph API.

- **Pending Certificate Request SAN**

  Fixed an issue in which pending certificate requests containing a User Principal Name (UPN) in the Subject Alternative Name (SAN) would be prefixed with '[0]', and IPv6 addresses were not displayed.

- **vSCEP Challenge Error**

  Fixed an issue in which attempting to obtain a Validated SCEP (vSCEP) challenge resulted in an assembly loading error.

- **Denied Alert Email SAN**

  Fixed an issue in which Denied Certificate Alert email did not contain the certificate Subject Alternative Names (SANs).

- **Expiration Alert Logging**

  Fixed an issue in which excessive and superfluous log messages were generated during Expiration Alert processing.

Note: No changes were made to the Keyfactor Universal Orchestrator in this release, as such the 9.5 version of the Universal Orchestrator should still be considered the latest and is fully compatible with the Keyfactor Command 9.8 release.

API Endpoint Change Log

No API endpoint changes were made in this release.

6.2.9 Incremental Release 9.9 Notes

May 2022

Note: Keyfactor Command 9.9 is a minor release with incremental fixes and updates following the Keyfactor Command 9 major release. For more details on new features, improvements, and known limitations in Keyfactor Command 9.0, please review the Major Release 9.0 Notes on page 2510.

New Features

Metadata Access on View Inventory Dialog

- **What problem does it solve?**

  The View Inventory dialog for certificate stores previously displayed each certificate found in the certificate store but did not include the Keyfactor Command metadata field values configured for the certificates.

- **How does it work?**

The View Inventory dialog on the Certificate Stores page now includes a Metadata section to allow you to view the metadata fields configured in Keyfactor Command for each certificate found in the certificate store.

- **What's the benefit?**

  Streamlining: You no longer need to look up the metadata fields for the certificates separately.

Updates and Improvements

- **GET /Agents Keyfactor API Endpoint**

  The GET /Agents Keyfactor API endpoint now includes a query parser to allow searching by AgentId. For example:.

  ```
  AgentId -eq "d2f0d545-c3b3-4ea3-bc0a-0232865e24c3"
  ```

- **Logging**

  Changes have been made to the way that Keyfactor Command logs are initialized to support logging from multiple source libraries including Quartz.

- **Alerts Do Not Resume After a Database Connection Failure**

  Fixed an issue in which expiration alerts and pending, issued, and denied certificate alerts that failed due to a database connection problem would not restart on resolution of the database connection issues until the Keyfactor Command service was restarted.

- **Revoke All of Entirely Revoked or Expired Certificates Fails**

  Fixed an issue in which attempting to revoke all for a group of certificates that contains only certificates that are revoked already and/or expired results in an error message.

- **SSH Server Groups Incompatible with Domain Names Containing Hyphens**

  Fixed an issue in which SSH server groups could not be created in environments where the Keyfactor Command domain contains a hyphen because the SSH server group owner field would not support a hyphen in the domain name.

- **Certificate Signing Requests Can Produce an Error on Decoding**

  Fixed an issue in which CSR decoder used in CSR enrollment can produce an error on decoding the CSR under select circumstances. These can include SCEP requests with no SANs and CSRs with no extensions.

- **Keyfactor API GET Requests with a Sort Produce a 500 Error**

  Fixed an issue in which Keyfactor API GET endpoints that support query sorting in the URL would produce a 500 error if the sort field was not provided correctly (e.g. the fieldname was entered with a space or was a valid fieldname but not one that was supported for sorting).

Note: No changes were made to the Keyfactor Universal Orchestrator in this release, as such the 9.5 version of the Universal Orchestrator should still be considered the latest and is fully compatible with the Keyfactor Command 9.9 release.

API Endpoint Change Log

The following changes were made to the API endpoints. Please review these carefully if you have implemented any integration using these endpoints.

Table 780: API Change Log

Endpoint	Methods	Action	Notes
/Reports/<any>	GET	Fix	Spaces within the sortField no longer results in an exception.
/Reports/{id}/Schedules	GET	Fix	An invalid sortField no longer results in an exception.
/Agents	GET	Update	New query parser to support the AgentId GUID.

6.2.10 Incremental Release 9.10 Notes

June 2022

Note: Keyfactor Command 9.10 is a minor release with incremental fixes and updates following the Keyfactor Command 9 major release. For more details on new features, improvements, and known limitations in Keyfactor Command 9.0, please review the Major Release 9.0 Notes on page 2510.

Updates and Improvements

- **Enrollment**

  The enrollment options in Keyfactor Command now support enrolling for SubCA type certificates.

- **Expiration Alert Renewal Handler**
  - Fixed an issue where the expiration alert renewal handler would generate an error if the alert contained more than one email recipient.
  - Fixed an issue where the expiration alert renewal handler would not run on databases that had been upgraded from versions of Keyfactor Command prior to 5.

- **PAM Secret Storage**

  Fixed an issue where PAM parameters of type secret (often passwords) weren't being loaded in Keyfactor Command correctly when returned from the PAM provider.

Note: No changes were made to the Keyfactor Universal Orchestrator in this release, as such the 9.5 version of the Universal Orchestrator should still be considered the latest and is fully compatible with the Keyfactor Command 9.10 release.

API Endpoint Change Log

No API endpoint changes were made in this release.

6.3 Major Release 8.0 Notes

October 2020

Highlights

SSH Key Management

Our new module, SSH Key Manager, gives security and network teams a simple, centralized solution to simplify SSH key management and mitigate the risk of emerging SSH-based attacks.

The SSH Key Manager allows you to:

- **Discover**: Inventory SSH authorized_keys across your servers and cloud infrastructure
- **Analyze**: Review your key inventory to detect and remediate things like unauthorized root access, stale keys, and keys that belong to users that should no longer have access
- **Rotate**: Configure automated key rotation alerts and enable self-service key generation and rotation by SSH users
- **Automate**: Keep DevOps and admin teams moving with automated key deployment, which can be baked into the server provisioning process in highly automated cloud environments
- **Report**: Generate reports to keep an eye on user and service account keys in your environment, including their lifecycle, access, and trust relationships

Note: If you are re-installing the Keyfactor Bash Orchestrator, you must run the uninstall.sh script before re-running the install.sh script.

Note: The certificate used during the Keyfactor Bash Orchestrator installation needs to be in PEM format.

User Interface Improvements

- Links to the specific areas of the Keyfactor Command documentation are now available in the application.
- Adding a certificate to a certificate store has been updated from the previous tree view control to a search-able grid to make management of certificate stores at scale more efficient.
- Grids have changed to allow selecting via checkboxes and to include tabs to make the less frequently used functions grouped in a less front and center way.
- Some areas of the application now have expandable/collapsible functionality to hide information when it isn't needed to provide a cleaner interface.

CA Authorization

You can now enter explicit credentials when contacting the CA. The requester will be provided in the request in order to track who is acting on the CA. Additionally, permissions for who can enroll for a certificate can be defined on a Keyfactor Command Security Role level.

Updates and Improvements

- **Installation**

  Default installation path changes from "Certified Security Solutions" to "Keyfactor".

- **Installation**

  Installation now requires Remote Server Administration Tools Active Directory PowerShell Module.

- **Administration**

  Application Settings are now accessible via the gear icon.

- **Certificates**

  Certificate Collections are now under the Certificates menu item.

- **Certificate Revocation—Hold**

  Certificates that have been revoked with a reason of "Certificate Hold" can now have the hold removed.

Deprecation/Required Upgrades

- **Windows Server 2012 R2**

  Support for Windows Server 2012 R2 has been deprecated in Keyfactor Command 8, since it has also been deprecated by Microsoft, and is no longer functioning well with newer backend technologies that our software uses. Customers should upgrade to Windows Server 2019.

- **User Enrollment Portal**

  In Keyfactor Command 8, the support for the User Enrollment Portal (which allows users to go to a browser page to enroll for a certificate—this is NOT the enrollment section of the Keyfactor Command Management Portal)—are deprecated.

  - iOS enrollment
  - Android enrollment
  - ActiveX PFX enrollment (based on whenever Microsoft phases out Internet Explorer as, at that point, ActiveX will not be available)
  - User PFX enrollment (user build-from-AD certs, NOT the web server PFX in the main Management Portal)

  It is recommended not to do new deployments of these features and to plan for migration away or an in-house support option.

- **Expiration Renewals**

  Existing expiration renewals will need to have the URLs updated to point to the KeyfactorAPI instead of the CMSAPI.

- **Active Directory**

In future releases the ability to use the Active Directory password on PFX enrollment will be deprecated as we upgrade to allow authentication methods other than Active Directory.

Known Issues/Limitations

Administration

- Daylight Savings Time (DST) is now shown as the time zone locale for the clients using Keyfactor Command, rather than as the UTC offset, which is what Microsoft CA uses. This causes issues during DST in time zones that do not have DST to appear off by an hour.
- Microsoft IIS settings to change authentication to support the "Use Active Directory Password" application setting for the Keyfactor Command portal must be made manually.
- When using Basic Authentication, the authentication in Microsoft IIS may need to be configured manually for the KeyfactorAnalysis portal.
- Authentication between the KeyfactorPortal, KeyfactorAPI, and KeyfactorAnalysis sites needs to be configured with the same authentication type, SSL, and host name.

Certificates

- Editing certificate details on a collection for a CA while an initial sync is running on the CA will cause inaccurate numbers to display in the Edit All window.
- If a CA is not scheduled to sync under "PKI Management" it will not appear in lists to select for things like inclusion in "Dashboards and Reports".
- Syncing an Issuing CA before syncing its parents in the chain causes Keyfactor Command to show the wrong requester for the chain certificates.
- Keyfactor Command cannot support a CA in the local forest with the same NetBIOS name as a CA in a trusted forest.
- In some upgrade cases, the Certificate Search page only partially loads or enrollment returns a System.Exception error. Opening the Developer Tools with F12 key and performing an Empty Cache and Hard Reload will resolve this problem.

Infrastructure

- Running large SSL scans can impact Keyfactor Command application performance if the Windows Agent/Orchestrator performing the scan is installed on the same server as the Keyfactor Command portal.
- If you receive an error when opening the portal that "the underlying connection was closed" please be sure you have all of the latest Windows Updates installed.

Reporting

- In Windows, drive mapping is done on a per-user basis. If you would like scheduled reports to be saved to a mapped drive, the timer service account needs to have that mapping created for them beforehand.

- Exporting a report to Microsoft Excel can fail with a 401 error in Microsoft Edge. Chrome or Firefox can successfully export to Excel. This problem is being worked on by the reporting engine vendor (Logi Analytics).
- Users configured for Logi Analytics reporting cannot have double quotes in the password field.

UI

- Occasionally, the "Please Wait" message will hang. Control + F5 will fix this.

6.3.1 Incremental Release 8.1 Notes

November 2020

Note: Keyfactor Command 8.1 is a minor release with incremental fixes and updates following the Keyfactor Command 8 major release. For more details on new features, improvements, and known limitations in Keyfactor Command 8.0, please review the Major Release 8.0 Notes on page 2542.

New Features

- **Scriptable Windows Orchestrator Installation**

  The Windows Orchestrator now supports a fully scriptable installation.
- **Pending Requests Show AD Information**

  Pending requests now show the information that would be populated from AD such as Distinguished Name, Common Name, and Subject Alternative Names.
- **AnyAgent Management Job can Trigger an Inventory Job**

  If an inventory job id is returned to an AnyAgent in the completion call of a management job, the inventory job will be initiated after the management job completes.
- **UPN as SAN**

  Added support for UPN as a SAN type when enrolling through Keyfactor Command.
- **P7B Import**

  A P7B file can be imported into Keyfactor Command via the Certificate Import UI and API without having to be converted to another file format.

Updates and Improvements

- **Infrastructure**

  Fixed an issue in the configuration wizard with SQL authentication and with enabling the CMSAPI when using a saved configuration file.
- **SSL Discovery & Monitoring**

  Fixed an issue with network ranges disappearing in the UI on edit.
- **Expiration Alerts**

Expiration renewal emails now contain the success or failure of the renewal job.

- **Certificate Templates**

  Fixed an issue that was preventing newly created certificate templates from being imported.

- **Reporting**

  Fixed an issue where the report manager incorrectly reported unsaved changes.

- **Certificate Stores**

  Fixed an issue to allow NetScaler certificates to be renewed even if the original certificate at the endpoint did not have the private key.

- **Certificate Metadata**

  Fixed an issue where big text metadata fields that contained XML or line breaks were causing an audit signing mismatch.

- **Management Portal**

  Updated the error message displayed when using IE to be more descriptive that IE is no longer supported.

- **Certificate Metadata**

  Added non-US date formats to the metadata date field validation.

- **Certificate Revocation**

  Fixed an issue with revocation and non-US date time formats.

- **Management Portal**

  Adjustments to font color in some areas of the portal and reports for better visibility.

- **Management Portal**

  Minor UI fixes and updates.

- **SSL Discovery & Monitoring**

  Fixed an issue with SSL endpoints being marked as reviewed or monitored in bulk.

- **API**

  Fixed a problem where the GET SSL/Networks API endpoint was ignoring the querystring value passed to it.

- **API**

  Updates to Swagger API documentation continue.

- **Certificate Stores**

  Certificate store management job custom fields now display when scheduling management job.

- **Certificate Stores**

  On PFX Enrollment, removed the requirement for the NetScaler server name when deploying to Netscaler.

- **Certificate Stores**

  Revoked Certificates in Certificate Stores report now accepts a collection as a parameter.

- **Dashboard**

  Fixes to allow parenthesis in the CRL Revocation Monitoring URLs used in the Dashboard.

- **Certificates**

  Fixed a re-issued certificate problem that had a field incorrectly filled in.
- **SSL Discovery & Monitoring**

  Fixed an issue in SSL network definitions to restore the ability to add a range of ports.
- **CSR Generation**

  Fixed an issue with the CSR Generation page reporting an invalid template.
- **Orchestrators**

  Disapproved orchestrators are now hidden by default in the Orchestrator Management page.
- **Enrollment**

  Allow enrollment with a CSR that has no CN and/or SAN.
- **CSR Generation**

  Removed the option for RSA 1024 from the CSR Generation page.
- **Reporting**

  Added DNS name to the Full Certificate Extract report.
- **Reporting**

  Expiration Report sorts on Expiration Date by default.

Known Issues/Limitations

- **Version**

  Version 8.0.4.0 is the correct version for Keyfactor Command 8.1.
- **Certificates**

  Deleting a collection that is used in an alert or a report schedule will fail without saying why. This will be updated in a future version. The workaround is to remove the collection from the report schedules and/or alerts and then deleting it.

6.3.2 Incremental Release 8.2 Notes

December 2020

Note: Keyfactor Command 8.2 is a minor release with incremental fixes and updates following the Keyfactor Command 8 major release. For more details on new features, improvements, and known limitations in Keyfactor Command 8.0, please review the Major Release 8.0 Notes on page 2542.

New Features

- **SSL/TLS Scanning Scheduling Updates**
  - The SSL scanning definitions have been updated to allow for multiple "Quiet Hours" windows. In addition, the API and UI now have support for a "Scan Now" option which will allow a scan to run if there is not already a current scan in process for that network definition.
  - SSL scans can now be defined with IP Addresses that have port ranges extending to 65535.
- **Windows Orchestrator Service Account**

  The Windows Orchestrator can now be configured to run with a service account without interactive logon rights.
- **API Updates**
  - Ability to run a one-time "Scan Now" SSL/TLS job.
  - Ability to search collections by the collection name.
- **Event Logging**

  CRL Event monitoring now includes the Validity Period in the event log message to help distinguish between root and issuing CAs.

Updates and Improvements

- **Reporting**

  Fixed an issue where reports failed to process de-duplication correctly using the "Ignore renewed certificate results by" option set on the certificate collection.
- **Reporting**

  Certificates by Revoker report updated to be clearer on who the revoker was.
- **API**

  Fixed an issue where metadata display order values were getting duplicated when updated via the API.
- **API**

  Fixed an issue where an API call to revoke a certificate was not being scheduled at the correct time.
- **Certificate Revocation**

  Addressed an issue where after revocation a certificate might still show up as Active in the Keyfactor Command Management Portal until the next sync.
- **Certificate Metadata**

  Fixed an issue in date time queries that was causing some metadata fields not to get updated with doing an "Edit All".
- **Reporting**

  Fixed an issue with editing report schedules failing to update the scheduled time.
- **Management Portal**

  Minor visual UI updates.

Deprecation/Required Upgrades

- **.NET 4.7.2**

  .NET version 4.7.2 is now required for systems hosting Keyfactor Windows Orchestrators.

6.3.3 Incremental Release 8.3 Notes

January 2021

Note: Keyfactor Command 8.3 is a minor release with incremental fixes and updates following the Keyfactor Command 8 major release. For more details on new features, improvements, and known limitations in Keyfactor Command 8.0, please review the Major Release 8.0 Notes on page 2542.

New Features

- **Increased Allowed Number of Certificate Store Types**

  Added support for a larger number of custom certificate store types.
- **SSH Updates**
  - An Access Management tab has been added to the user dialog that allows for the management of a user's logons.
  - Addition of a new SSH Users Management page.
  - Regular expressions have been added so administrators can put parameters around the strength of passphrases.
- **Default Certificate Collections on a New Installation**

  A new installation of Keyfactor Command will provide a default "My Certificates" collection.
- **API Changes**

  A certificate's SSL locations can now be returned from the API.
- **Certificate Changes**
  - During a re-enrollment default metadata fields are populated if the old certificate had blank values for the metadata.
  - Pending requests now show the denial reason.
  - Added the internal Keyfactor Command ID to the certificate details page to aid in searching and in API calls.

Updates and Improvements

- **ACME**

  Addressed an issue with the ACME server retrieving certs with PEM encoding.

- **Orchestrator**

  Added a check in the Java Agent installer for .NET framework 4.7.2.

- **Certificate Stores**

  F5 Certificate Stores return the F5 version.

- **API**

  Fixed an issue with PUT and POST endpoints for SSL/Networks not setting required default values.

- **API**

  Fixed an issue with the Template PUT calls not setting RegEx values properly.

- **API**

  Performance improvements made to the GET certificates API call.

- **Certificate Stores**

  Fixed an issue where updating a certificate store causing credentials to be nulled out.

- **Installation**

  Added a check in the configuration wizard to ensure a second Azure SQL database cannot be created to help avoid inadvertent Azure costs being incurred and addressed a issue requiring access to the master database during configuration with Azure SQL.

- **API**

  Fixed an issue where GET /Templates was returning incorrect values for UseAllowedRequesters and nothing for AllowedRequesters and EnrollmentFields.

- **API**

  PUT /CertificateStores/DiscoveryJob endpoint now sets the job as immediate when JobExecutionTimestamp is not provided.

- **Orchestrator Blueprints**

  Fixed an error when manually applying a blueprint to an agent.

- **Certificate Metadata**

  Fixed an issue with metadata history not being saved when updated via the API.

- **Security**

  Addressed a security role permission that incorrectly disallowed Edit All on certificates.

- **Orchestrator**

  Fixed an issue with the scripted installation of the Windows Agent not properly saving the configuration.

- **API**

  Fixed an issue with setting the Java Agent password via the PUT CertificateStores/Password API call.

- **Auditing**

  Fixed some issues with audit searching.

- **CA Synchronization**

  Fixed an issue with the CA sync missing certificates if the CA database had deleted rows.

- **API**

  Expanded permissions to the PUT Certificates/Collection API role so that administrator access is not required.
- **Certificate Search**

  Fixed a UI issue with certificates searches returning revoked and expired certificates due to missing parenthesis in the query.
- **Orchestrator**

  Fixed an issue with Mac Auto-enrollment failing.
- **Certificate**

  Added the ability to expand the cert request ID information from the portal.
- **Expiration Alerts**

  Added support in expiration alerts queries for '-includes' and '-notincludes' comparisons.
- **CRL Alerts**

  Fixed an issue with removing a recipient from a CRL alert.

6.3.4 Incremental Release 8.4 Notes

January 2021

Note: Keyfactor Command 8.4 is a minor release with incremental fixes and updates following the Keyfactor Command 8 major release. For more details on new features, improvements, and known limitations in Keyfactor Command 8.0, please review the Major Release 8.0 Notes on page 2542.

New Features

- **Default Collections**

  Certain default collections are now included with a new installation. These include:
  - Certificates expiring in 7 days
  - Revoked certificates
  - Self-signed certificates
  - Certificates with weak encryption

  Note: Default collections are not included in upgrades.
- **Azure SQL Support in ACME**

  Keyfactor ACME now natively supports Azure SQL.

Updates and Improvements

- **Enrollment**

  Fixed an issue in which the PFX subject format from the application setting was not properly applied.
- **Dashboard**

  A fix to the dashboard where the CRL panel is returning HTTP 404 errors.
- **Management Portal**

  Custom banner widths are now fully supported and will not distort graphics.

6.3.5 Incremental Release 8.5 Notes

February 2021

Note: Keyfactor Command 8.5 is a minor release with incremental fixes and updates following the Keyfactor Command 8 major release. For more details on new features, improvements, and known limitations in Keyfactor Command 8.0, please review the Major Release 8.0 Notes on page 2542.

New Features

- **SAN Count**

  The number of Subject Alternative Names (SANs) on a certificate is now available on the certificate details page as well as in the Full Certificate Extract Report.

Updates and Improvements

- **Orchestrator**

  The F5 REST Orchestrator has been updated to address and issue with inventorying a store with more than 20 records.
- **Security**

  Fixed an issue in which combining global and collection-level permissions for accounts resulted in an OutOfMemory exception.
- **Documentation**

  The *Keyfactor Web APIs Reference Guide* is now available via the Management Portal.
- **Log Shipping**

  Syslog is now supported over TLS for improved log shipping security.
- **Orchestrator**

  IAgentRegistrationHandler interface has been changed to IOrchestratorRegistrationHandler to provide for better namespace accuracy.
- **Active Directory**

Active Directory groups with an ampersand in the group name can now be used in Keyfactor Command security identities.

- **API**

  An API endpoint has been added to the Keyfactor API to allow for deletion of a certificate from a certificate store.

- **Orchestrator**

  The server name can be passed as a parameter to KeyfactorWindowsAgentConsoleConfig.exe to allow for more flexibility in scripted deployments.

- **Reporting**

  The Full Certificate Extract Report now supports metadata parameters.

- **Reporting**

  Fixed an issue with the Expiration Report not processing de-duplication correctly using the "Ignore renewed certificate results by" option set on the certificate collection.

Deprecation/Required Upgrades

- **Stale CRL Monitoring**

  In a future version of Keyfactor Command, the CRL Stale monitoring will be replaced with letting customers define their own "Stale" by generating alerts—and log entries—off of the date that the CRL expires, rather than looking at the Next Publish date.

  The main reason for that is that there is, by definition, a race condition between when the new CRL gets created (exactly at the Next Publish time), and when it is copied to the CRL distribution points. Basing alerts off CRL expiration allows customers to tune timeframes based on the way they handle their CRLs.

- **Verbosity in API Calls**

  In a future version of Keyfactor Command, the Keyfactor API will return all data regardless of the verbosity level. For backwards compatibility where performance is concerned, verbosity will be honored when loading certificate location data in the certificate query but has been replaced with new flags to include this data for future requests.

6.3.6 Incremental Release 8.6 Notes

March 2021

Note: Keyfactor Command 8.6 is a minor release with incremental fixes and updates following the Keyfactor Command 8 major release. For more details on new features, improvements, and known limitations in Keyfactor Command 8.0, please review the Major Release 8.0 Notes on page 2542.

Updates and Improvements

- **Orchestrator**

  Updates to Java Agent hostname support to allow for manual hostname entry.
- **Reporting**

  Password encryption in the Logi Analytics configuration file.
- **Certificates**

  Fixed an issue in saving certificate collections.
- **Certificates**

  Fixed the issue in which searching for certificates by EKU was not working properly.
- **Auditing**

  Modified audit logging to properly load certificate download operations.
- **SSL Discovery & Monitoring**

  Corrected an issue in which SSL scan details could not be displayed if the associated schedule is not defined.
- **API**

  Fixed an issue in which password regular expression validation was not enforced for API-based requests.
- **SSL Discovery & Monitoring**

  Updated the SSL search parser to search all octets instead of only the first two.
- **Orchestrator**

  Fixed an error in the Java Agent packaging in which the RPM and local did not build the correct commandline not providing the proper path.

6.3.7 Incremental Release 8.7 Notes

April 2021

Note: Keyfactor Command 8.7 is a minor release with incremental fixes and updates following the Keyfactor Command 8 major release. For more details on new features, improvements, and known limitations in Keyfactor Command 8.0, please review the Major Release 8.0 Notes on page 2542.

Updates and Improvements

- **Infrastructure**

  The SQL db_owner role is no longer required during operation of the Keyfactor Command platform.
- **Reporting**

  A new report—Certificate Issuance Trends—is now available.
- **Management Portal**

Apostrophes are now permitted in Certificate Revocation Lists (CRL) display names.

- **Auditing**

  Audit Syslog supports TLS 1.2.

- **Certificates**

  Update to EV DigiCert renewal functionality to fix truncation of long Distinguished Names (DNs).

- **Security**

  Fix so that Read permission on the System Settings is no longer required to edit certificate store containers.

- **Management Portal**

  Fix to management portal data grids to prevent improper display when the last row is blocked by the scroll bar after resizing.

- **API**

  Updated certificate store API endpoints to display them properly in the API endpoint utility (Swagger).

6.4 Keyfactor Command v10 Compatibility Matrix

All supported Keyfactor Command versions' compatibility with the various supported Keyfactor gateways, agents and orchestrators is shown in Table 781: Compatibility Matrix (with Compatibility Matrix Legend on the next page).

Table 781: Compatibility Matrix

Product	Version	10.3	10.2	10.1	10.0
Universal Orchestrator	10.0.1	✓	✓	✓	✓
Universal Orchestrator	9.4.0	✓	✓	✓	✓
Universal Orchestrator	9.3.0	✓	✓	✓	✓
Universal Orchestrator	9.2.0	✓	✓	✓	✓

7.0 Glossary

A

AIA

The authority information access (AIA) is included in a certificate--if configured--and identifies a location from which the chain certificates for that certificate may be retrieved.

AnyAgent

The AnyAgent, one of Keyfactor's suite of orchestrators, is used to allow management of certificates regardless of source or location by allowing customers to implement custom agent functionality via an API.

AnyGateway

The Keyfactor AnyGateway is a generic third party CA gateway framework that allows existing CA gateways and custom CA connections to share the same overall product framework.

API

A set of functions to allow creation of applications. Keyfactor offers the Keyfactor API, which allows third-party software to integrate with the advanced certificate enrollment and management features of Keyfactor Command.

Argument

A parameter or argument is a value that is passed into a function in an application.

Authority Information Access

The authority information access (AIA) is included in a certificate--if configured--and identifies a location from which the chain certificates for that certificate may be retrieved.

B

Bash Orchestrator

The Bash Orchestrator, one of Keyfactor's suite of orchestrators, is used to discover and manage SSH keys across an enterprise.

Blueprint

A snapshot of the certificate stores and scheduled jobs on one orchestrator, which can be used to create matching certificate stores and jobs on another orchestrator with just a few clicks.

C

CA

A certificate authority (CA) is an entity that issues digital certificates. Within Keyfactor Command, a CA may be a Microsoft CA or a Keyfactor gateway to a cloud-based or remote CA.

Certificate Authority

A certificate authority (CA) is an entity that issues digital certificates. Within Keyfactor Command, a CA may be a Microsoft CA or a Keyfactor gateway to a cloud-based or remote CA.

Certificate Revocation List

A Certificate Revocation List (CRL) is a list of digital certificates that have been revoked by the issuing Certificate Authority (CA) before their scheduled expiration date and should no longer be trusted.

Certificate Signing Request

A CSR or certificate signing request is a block of encoded text that is submitted to a CA when enrolling for a certificate. When you generate a CSR within Keyfactor Command, the matching private key for it is stored in Keyfactor Command in encrypted format and will be married with the certificate once returned from the CA.

CN

A common name (CN) is the component of a distinguished name (DN) that represents the primary name of the object. The value varies depending on the type of object. For a user object, this would be the user's name (e.g. CN=John Smith). For SSL certificates, the CN is typically the fully qualified domain name (FQDN) of the host where the SSL certificate will reside (e.g. server-name.keyexample.com or www.keyexample.com).

Collection

The certificate search function allows you to query the Keyfactor Command database for certificates from any available source based on any criteria of the certificates and save the results as a collection that will be availble in other places in the Management Portal (e.g. expiration alerts and certain reports).

Common Name

A common name (CN) is the component of a distinguished name (DN) that represents the primary name of the object. The value varies depending on the type of object. For a user object, this would be the user's name (e.g. CN=John Smith). For SSL certificates, the CN is typically the fully qualified domain name (FQDN) of the host where the SSL certificate will reside (e.g. server-name.keyexample.com or www.keyexample.com).

Configuration Tenant

A grouping of CAs. The Microsoft concept of forests is not used in EJBCA so to accommodate the new EJBCA functionality, and to avoid confusion, the term forest needed to be renamed. The new name is configuration tenant. For EJBCA, there would be one configuration tenant per EJBCA server install. For Microsoft, there would be one per forest. Note that configuration tenants cannot be mixed, so Microsoft and EJBCA cannot exist on the same configuration tenant.

CRL

A Certificate Revocation List (CRL) is a list of digital certificates that have been revoked by the issuing Certificate Authority (CA) before their scheduled expiration date and should no longer be trusted.

CSR

A CSR or certificate signing request is a block of encoded text that is submitted to a CA when enrolling for a certificate. When you generate a CSR within Keyfactor Command, the matching private key for it is stored in Keyfactor Command in encrypted format and will be married with the certificate once returned from the CA.

D

DER

A DER format certificate file is a DER-encoded binary certificate. It contains a single certificate and does not support storage of private keys. It sometimes has an extension of .der but is often seen with .cer or .crt.

Distinquished Name

A distinguished name (DN) is the name that uniquely identifies an object in a directory. In the context of Keyfactor Command, this directory is generally Active Directory. A DN is made up of attribute=value pairs, separated by commas. Any of the attributes defined in the directory schema can be used to make up a DN.

DN

A distinguished name (DN) is the name that uniquely identifies an object in a directory. In the context of Keyfactor Command, this directory is generally Active Directory. A DN is made up of attribute=value pairs, separated by commas. Any of the attributes defined in the directory schema can be used to make up a DN.

DNS

The Domain Name System is a service that translates names into IP addresses.

E

ECC

Elliptical curve cryptography (ECC) is a public key encryption technique based on elliptic curve theory that can be used to create faster, smaller, and more efficient cryptographic keys. ECC generates keys through the properties of the elliptic curve equation instead of the traditional method of generation as the product of very large prime numbers.

Endpoint

An endpoint is a URL that enables the API to gain access to resources on a server.

Enrollment

Certificate enrollment refers to the process by which a user requests a digital certificate. The user must submit the request to a certificate authority (CA).

EOBO

A user with an enrollment agent certificate can enroll for a certificate on behalf of another user. This is often used when provisioning technology such as smart cards.

F

Forest

An Active Directory forest (AD forest) is the top most logical container in an Active Directory configuration that contains domains, and objects such as users and computers.

G

Gateway Connector

The Keyfactor Gateway Connector is installed in the customer forest to provide a connection between the on-premise CA and the Azure-hosted, Keyfactor managed Hosted Configuration Portal to provide support for synchronization, enrollment and management of certificates through the Azure-hosted instance of Keyfactor Command for the on-premise CA. It is supported on both Windows and Linux.

H

Host Name

The unique identifier that serves as name of a computer. It is sometimes presented as a fully qualified domain name (e.g. server-name.keyexample.com) and sometimes just as a short name (e.g. servername).

Hosted Config Portal

The Keyfactor Hosted Configuration Portal is used to configure connections between on-premise instances of the Keyfactor Gateway Connector and and on-premise CAs to make them available to Azure-hosted instance of Keyfactor Command.The portal is Azure-hosted and managed by Keyfactor.

Hosted Configuration Portal

The Keyfactor Hosted Configuration Portal is used to configure connections between on-premise instances of the Keyfactor Gateway Connector and and on-premise CAs to make them available to Azure-hosted instance of Keyfactor Command.The portal is Azure-hosted and managed by Keyfactor.

Hostname

The unique identifier that serves as name of a computer. It is sometimes presented as a fully qualified domain name (e.g.

servername.keyexample.com) and sometimes just as a short name (e.g. servername).

J

Java Agent

The Java Agent, one of Keyfactor's suite of orchestrators, is used to perform discovery of Java keystores and PEM certificate stores, to inventory discovered stores, and to push certificates out to stores as needed.

Java Keystore

A Java KeyStore (JKS) is a file containing security certificates with matching private keys. They are often used by Java-based applications for authentication and encryption.

JKS

A Java KeyStore (JKS) is a file containing security certificates with matching private keys. They are often used by Java-based applications for authentication and encryption.

K

Key Length

The key size or key length is the number of bits in a key used by a cryptographic algorithm.

Key Pair

In asymmetric cryptography, public keys are used together in a key pair with a private key. The private key is retained by the key's creator while the public key is widely distributed to any user or target needing to interact with the holder of the private key.

Key Size

The key size or key length is the number of bits in a key used by a cryptographic algorithm.

Key Type

The key type identifies the type of key to create when creating a symmetric or asymmetric key. It references the signing algorithm and often key size (e.g. AES-256, RSA-2048, Ed25519).

Keyfactor CA Management Gateway

The Keyfactor CA Management Gateway is made up of the Keyfactor Gateway Connector, installed in the customer forest to provide a connection to the local CA, and the Azure-hosted and Keyfactor managed Hosted Configuration Portal. The solution is used to provide a connection between a customer's on-premise CA and an Azure-hosted instance of Keyfactor Command for synchronization, enrollment, and management of certificates.

Keyfactor Gateway Connector

The Keyfactor Gateway Connector is installed in the customer forest to provide a connection between the on-premise CA and the Azure-hosted, Keyfactor managed Hosted Configuration Portal to provide support for synchronization, enrollment and management of certificates through the Azure-hosted instance of Keyfactor Command for the on-premise CA. It is supported on both Windows and Linux.

Keyfactor Universal Orchestrator

The Keyfactor Universal Orchestrator, one of Keyfactor's suite of orchestrators, is used to interact with Windows servers (a.k.a. IIS certificate stores) and FTP capable devices for certificate management, run SSL discovery and management tasks, and manage synchronization of certificate authorities in remote forests. With the addition of custom extensions, it can run custom jobs to provide certificate management capabilities on a variety of platforms and devices (e.g. F5 devices, NetScaler devices, Amazon Web Services (AWS) resources) and execute tasks outside the standard list of certificate management functions. It runs on either Windows or Linux.

Keystore

A Java KeyStore (JKS) is a file containing security certificates with matching private keys. They are often used by Java-based applications for authentication and encryption.

L

Logical Name

The logical name of a CA is the common name given to the CA at the time it is created. For Microsoft CAs, this name can be seen at the top of the Certificate Authority MMC snap-in. It is part of the FQDN\Logical Name string that is used to refer to CAs when using command-line tools and in some Keyfactor Command configuration settings (e.g. ca2.keyexample.com\Corp Issuing CA Two).

M

MAC Agent

The MAC Agent, one of Keyfactor's suite of orchestrators, is used to manage certificates on any keychains on the Mac on which the Keyfactor MAC Agent is installed.

Metadata

Metadata provides information about a piece of data. It is used to summarize basic information about data, which can make working with the data easier. In the context of Keyfactor Command, the certificate metadata feature allows you to create custom metadata fields that allow you to tag certificates with tracking information about certificates.

O

Object Identifier

Object identifiers or OIDs are a standardized system for identifying any object, concept, or "thing" with a globally unambiguous persistent name.

OID

Object identifiers or OIDs are a standardized system for identifying any object, concept, or "thing" with a globally unambiguous persistent name.

Orchestrator

Keyfactor orchestrators perform a variety of functions, including managing certificate stores and SSH key stores.

P

P12

A PFX file (personal information exchange format), also known as a PKCS#12 archive, is a single, password-protected certificate archive that contains both the public and matching private key and, optionally, the certificate chain. It is a common format for Windows servers.

P7B

A PKCS #7 format certificate file is a base64-encoded certificate. Since it's presented in ASCII, you can open it in any text editor. PKCS #7 certificates always begin and end with entries that look something like ---- BEGIN CERTIFICATE---- and ---- END CERTIFICATE----. Unlike PEM files, PKCS #7 files can contain only a certificate and its certifiate chain but NOT its private key. Extensions of .p7b or .p7c are usually seen on certificate files of this format.

P7C

A PKCS #7 format certificate file is a base64-encoded certificate. Since it's presented in ASCII, you can open it in any text editor. PKCS #7 certificates always begin and end with entries that look something like ---- BEGIN CERTIFICATE---- and ---- END CERTIFICATE----. Unlike PEM files, PKCS #7

files can contain only a certificate and its certifiate chain but NOT its private key. Extensions of .p7b or .p7c are usually seen on certificate files of this format.

Parameter

A parameter or argument is a value that is passed into a function in an application.

PEM

A PEM format certificate file is a base64-encoded certificate. Since it's presented in ASCII, you can open it in any text editor. PEM certificates always begin and end with entries like ---- BEGIN CERTIFICATE---- and ----END CERTIFICATE----. PEM certificates can contain a single certificate or a full certifiate chain and may contain a private key. Usually, extensions of .cer and .crt are certificate files with no private key, .key is a separate private key file, and .pem is both a certificate and private key.

PFX

A PFX file (personal information exchange format), also known as a PKCS#12 archive, is a single, password-protected certificate archive that contains both the public and matching private key and, optionally, the certificate chain. It is a common format for Windows servers.

PKCS #7

A PKCS #7 format certificate file is a base64-encoded certificate. Since it's presented in ASCII, you can open it in any text editor. PKCS #7 certificates always begin and end with entries that look something like ---- BEGIN CERTIFICATE---- and ----END CERTIFICATE----. Unlike PEM files, PKCS #7 files can contain only a certificate and its certifiate chain but NOT its private key. Extensions of .p7b or .p7c are usually seen on certificate files of this format.

PKCS#12

A PFX file (personal information exchange format), also known as a PKCS#12 archive, is a single, password-protected certificate archive that contains both the public and matching private key and, optionally, the certificate chain. It is a common format for Windows servers.

PKI

A public key infrastructure (PKI) is a set of roles, policies, and procedures needed to create, manage, distribute, use, store and revoke digital certificates and manage public-key encryption.

Private Key

Private keys are used in cryptography (symmetric and asymmetric) to encrypt or sign content. In asymmetric cryptography, they are used together in a key pair with a public key. The private or secret key is retained by the key's creator, making it highly secure.

Public Key

In asymmetric cryptography, public keys are used together in a key pair with a private key. The private key is retained by the key's creator while the public key is widely distributed to any user or target needing to interact with the holder of the private key.

Public Key Infrastructure

A public key infrastructure (PKI) is a set of roles, policies, and procedures needed to create, manage, distribute, use, store and revoke digital certificates and manage public-key encryption.

R

Rogue Key

A rogue key, in the context of Keyfactor Command, is an SSH public key that appears in an

authorized_keys file on a server managed by the SSH orchestrator without authorization.

Root of Trust

A root of trust (RoT) is a source within a cryptographic system that can always be trusted. It is typically a hardened hardware module. HSMs (hardware security modules) and TPMs (trusted platform modules) are examples of RoTs.

RoT

A root of trust (RoT) is a source within a cryptographic system that can always be trusted. It is typically a hardened hardware module. HSMs (hardware security modules) and TPMs (trusted platform modules) are examples of RoTs.

RPC

Remote procedure call (RPC) allows one program to call a function from a program located on another computer on a network without specifying network details. In the context of Keyfactor Command, RPC errors often indicate Kerberos authentication or delegation issues.

rsyslog

Rsyslog is an open-source software utility used on UNIX and Unix-like computer systems for forwarding log messages in an IP network.

S

SAN

The subject alternative name (SAN) is an extension to the X.509 specification that allows you to specify additional values when enrolling for a digital certificate. A variety of SAN formats are supported, with DNS name being the most common.

server name indication

Server name indication (SNI) is an extension to TLS that provides for including the hostname of the target server in the initial handshake request to allow the server to respond with the correct SSL certificate or allow a proxy to forward the request to the appropriate target.

SMTP

Short for simple mail transfer protocol, SMTP is a protocol for sending email messages between servers.

SNI

Server name indication (SNI) is an extension to TLS that provides for including the hostname of the target server in the initial handshake request to allow the server to respond with the correct SSL certificate or allow a proxy to forward the request to the appropriate target.

SSH

The SSH (secure shell) protocol provides for secure connections between computers. It provides several options for authentication, including public key, and protects the communications with strong encryption.

SSL

TLS (Transport Layer Security) and its predecessor SSL (Secure Sockets Layer) are protocols for establishing authenticated and encrypted links between networked computers.

Subject Alternative Name

The subject alternative name (SAN) is an extension to the X.509 specification that allows you to specify additional values when enrolling for a digital certificate. A variety of SAN formats are supported, with DNS name being the most common.

T

Template

A certificate template defines the policies and rules that a CA uses when a request for a certificate is received.

TLS

TLS (Transport Layer Security) and its predecessor SSL (Secure Sockets Layer) are protocols for establishing authenticated and encrypted links between networked computers.

Trusted CA

A certificate authority in the forest in which Keyfactor Command is installed or in a forest in a two-way trust with the forest in which Keyfactor Command is installed.

U

Untrusted CA

A certificate authority in a forest in a one-way trust with the forest in which Keyfactor Command is installed or in a forest that is untrusted by the forest in which Keyfactor Command is installed. Non-domain-joined standalone CAs also fall into this category.

W

Web API

A set of functions to allow creation of applications. Keyfactor offers the Keyfactor API, which allows third-party software to integrate with the advanced certificate enrollment and management features of Keyfactor Command.

Windows Orchestrator

The Windows Orchestrator, one of Keyfactor's suite of orchestrators, is used to manage synchronization of certificate authorities in remote forests, run SSL discovery and management tasks, and interact with Windows servers as well as F5 devices, NetScaler devices, Amazon Web Services (AWS) resources, and FTP capable devices, for certificate management. In addition, the AnyAgent capability of the Windows Orchestrator allows it to be extended to create custom certificate store types and management capabilities regardless of source platform or location.

Workflow

A workflow is a series of steps necessary to complete a process. In the context of Keyfactor Command, it refers to the workflow builder, which allows you automate event-driven tasks when a certificate is requested or revoked.

X

x.509

In cryptography, X.509 is a standard defining the format of public key certificates. An X.509 certificate contains a public key and an identity (e.g. a host name or an organization or individual name), and is either signed by a certificate authority or self-signed. When a certificate is signed by a trusted certificate authority it can be used to establish trusted secure communications with the owner of the corresponding private key. It can also be used to verify digitally signed documents and emails.
