# **KEÝFACTOR**

# **Keyfactor Command 11.0**

Reference Guide

## **Table of Contents**

1.0 Introduction	. 1
2.0 Reference Guide	. 2
2.1 Using the Management Portal	
2.1.1 Authentication and Authorization	
2.1.2 Dashboard	
2.1.2.1 Dashboard: CA Status	
2.1.2.2 Dashboard: Collections	
2.1.2.3 Dashboard: Certificates by Signing Algorithm	. 14
2.1.2.4 Dashboard: Number of SSH Keys per Type	
2.1.2.5 Dashboard: Recent Certificate Store Jobs	. 16
2.1.2.6 Dashboard: Revocation Monitoring	. 17
2.1.2.7 Dashboard: SSL Endpoints	18
2.1.2.8 Dashboard: SSL Orchestrator Job Status	19
2.1.3 Certificate Search and Collections	.20
2.1.3.1 Certificate Details	20
2.1.3.2 Certificate Search Page	. 35
2.1.3.3 Certificate Operations	.46
2.1.3.4 Add Certificate	74
2.1.3.5 Certificate Collection Manager	.85
2.1.4 Reports	91
2.1.4.1 Certificate Count by Template	
2.1.4.2 Certificate Count by User per Template	. 95
2.1.4.3 Certificate Count Grouped by Single Metadata Field	. 97
2.1.4.4 Certificate Issuance Trends with Metadata	98
2.1.4.5 Certificates by Key Strength	100
2.1.4.6 Certificates by Revoker	101
2.1.4.7 Certificates by Type and Java Keystore	102
2.1.4.8 Certificates Found at TLS/SSL Endpoints	103
2.1.4.9 Certificates in Collection	104
2.1.4.10 Expiration Report	105
2.1.4.11 Expiration Report by Days	108
2.1.4.12 Full Certificate Extract Report	110
2.1.4.13 Issued Certificates per Certificate Authority	112
2.1.4.14 Monthly Executive Report	113
2.1.4.15 PKI Status for Collection	114
2.1.4.16 Revoked Certificates in Certificate Stores	120
2.1.4.17 SSH Key Usage	121
2.1.4.18 SSH Keys by Age	122
2.1.4.19 SSH Keys with Root Logon Access	123
2.1.4.20 SSH Trusted Public Keys with No Known Private Keys	124
2.1.4.21 Statistical Report	125
2.1.4.22 Report Manager	126
2.1.5 Enrollment	135
2.1.5.1 CSR Enrollment	136
2.1.5.2 CSR Generation	142
2.1.5.3 Pending CSRs	146
2.1.5.4 PFX Enrollment	146
2.1.5.5 Certificate Requests	163
2.1.6 Alerts	166
2.1.6.1 Expiration Alerts	
2.1.6.2 Pending Certificate Request Alerts	178
2.1.6.3 Issued Certificate Request Alerts	188
2.1.6.4 Denied Certificate Request Alerts	197
2.1.6.5 Key Rotation Alerts	203
2.1.6.6 Revocation Monitoring	210
2.1.6.7 Using Event Handlers	218

2	1.7 Workflow	. 229
	2.1.7.1 Workflow Definitions	. 230
	2.1.7.2 Workflow Instances	. 306
	2.1.7.3 My Workflows	. 325
2	1.8 Locations	. 349
	2.1.8.1 Certificate Authorities	350
	2.1.8.2 Certificate Templates	.380
	2.1.8.3 Certificate Stores	. 409
	2.1.8.4 SSL Discovery	. 454
2	1.9 Orchestrators	482
	2.1.9.1 Orchestrator Auto-Registration	.486
	2.1.9.2 Orchestrator Management	
	2.1.9.3 Orchestrator Job Status	
	2.1.9.4 Orchestrator Blueprints	
	2.1.9.5 Mac Auto-Enrollment	. 525
2	1.10 SSH	
	2.1.10.1 My SSH Key	
	2.1.10.2 Service Account Keys	
	2.1.10.3 Unmanaged SSH Keys	. 557
	2.1.10.4 Server Manager	
	2.1.10.5 SSH Permissions	
2	1.11 System Settings	
	2.1.11.1 Application Settings	
	2.1.11.2 Security Roles and Claims	
	2.1.11.3 Certificate Store Types	
	2.1.11.4 Certificate Metadata	
	2.1.11.5 Audit Log	
	2.1.11.6 Event Handler Registration	
	2.1.11.7 Privileged Access Management (PAM)	
	2.1.11.8 Identity Providers	
	2.1.11.9 SMTP Configuration	
	2.1.11.10 Component Installations	
	2.1.11.11 Licensing	
2.2	Operations	
	.2.1 Extending and Customizing Keyfactor Command	
	2.2.1.1 Customize the Management Portal Banner Logo	
	2.2.1.2 Keyfactor Command Appsetting json Files	
	2.2.1.3 Keyfactor Command Service Executable	
	2.2.1.4 Configuring Key Recovery for Keyfactor Command	
2	2.2 SSH Reference	
	2.2.2.1 SSH-Bash Orchestrator Job History Warning Resolution	
	2.2.2.2 SSH-SSSD Case Sensitivity Flag	
2	2.3 System Alerts	. 793
	2.4 Log Monitoring	
	2.2.4.1 Editing NLog	
	2.2.4.2 Audit Log Output to a Centralized Logging Solution	
	2.2.4.3 Keyfactor Command Windows Event IDs	
2	2.5 License Expiration Monitoring and Rotation	
	2.6 Disaster Recovery	
	2.2.6.1 SQL Encryption Key Backup	
2	2.7 SQL Database Migration	
	2.8 Troubleshooting	
	2.2.8.1 Disable Loopback Checking	
2.3	Appendices	
	3.1 Appendix - References	
	3.2 Appendix - Third-Party Notices for Keyfactor Command Software	
	2.3.2.1 Apache 2.0 License Text:	
	2.3.2.2 BSD License Text:	
	2.3.2.3 MIT License Text:

## 1.0 Introduction

The Keyfactor Command Documentation Suite includes:

- Keyfactor Command Reference Guide
- Keyfactor API Reference Guide
- Keyfactor Command Server Installation Guide
- Keyfactor Orchestrators Installation and Configuration Guide
- · Keyfactor Command Release Notes & Upgrading

In addition, Keyfactor offers documentation for products that are not part of the *Keyfactor Command Documentation Suite*, including the *Keyfactor Command Upgrade Overview* and installation guides for third-party CA gateways that interface with Keyfactor, which are available upon request.

### 2.0 Reference Guide

The *Reference Guide* for the Keyfactor Command solution by Keyfactor provides comprehensive instructions on using the Keyfactor Command Management Portal and Policy Module. The Management Portal is the command and control center for Keyfactor Command. From here, you can get a quick glance at the health of your PKI and a sense of how it is being used by visiting the dashboard, or delve into details of certificates using the certificate search feature. The Management Portal is also used to configure workflow and email notifications, enroll for certificates, and configure options that are used across the whole of the Keyfactor Command product.

This reference guide covers advanced configuration of Keyfactor Command in addition to providing usage information.

This guide is organized in the order of the Management Portal menu panel.

Figure 1: Management Portal Menu

### 2.1 Using the Management Portal

The Keyfactor Command Management Portal is a web-based application that you can open in any supported browser. The default URL for the Management Portal is (where KEYFACTOR\_SERVER\_FQDN is the FQDN of your Keyfactor Command administration server):

https://KEYFACTOR\_SERVER\_FQDN/keyfactorportal

In addition to the main URL, the pages in the Management Portal are available via deep link. To find the deep link for a page, just visit the page in your browser and copy the URL from the browser's URL line. For example, the deep link URL directly to the certificate search page in the Management Portal is available at:

https://KEYFACTOR SERVER FODN/keyfactorportal/CertificateCollection/Edit?cid=0

You can change the number at the end of this deep link to direct the deep link to a specific saved collection instead of the main search. You can find the collection number by browsing to the collection and viewing the URL in your browser. You can also build links to specific searches, rather than saved collections. For more information, see Certificate Search and Collections on page 20.

The following is some information to help you understand and use the Management Portal successfully.

#### **Navigating Keyfactor Command Grids**

The grid includes the following features:

Action buttons are used to perform actions on the data in the rows displayed in the grid. Some
buttons are grayed out until you click on a grid row, or if that action is unavailable for the
selected row. Which action buttons are displayed will depend on the function of the page.

**Note:** On some grids the actions are also available from the context menu, which is accessible by right-clicking on the selected row.

- The **Total** in the upper right of the grid will be updated each time you refresh the grid.
- The **Refresh** button will poll the Keyfactor Command database and update the grid with the results of the current page query and update the Total.
- To change a **column width**, click, hold and drag the line separating two column headers (to the right of the column you want to change).
- To **rearrange columns**, click on the header of the column you want to move and hold and drag the column to your selected location.
- To change the sort order of the grid, click on the header of the column you wish to sort by. The
  first time you click, the grid will be sorted in ascending order by the selected column. Click the
  column header again to reverse the sort order. When a column is sorted, a purple caret will
  appear at the end of the column name showing the direction of the sort. Lack of a caret indicates
  the grid is sorted by the default column and order. On some grids only select columns are sortable.
- Click anywhere on the row, or on the tick box in the far left column of a grid row, to select that
  row. You may select multiple rows by utilizing the standard Windows selection functions of
  CRTL/Select and SHIFT/Select to select multiple rows at once. Selected rows will be highlighted purple. You may then perform actions on the selected row(s) depending on the functionality of the grid by right-clicking and selecting an action (if available) or selecting an action
  from the action buttons at the top of the grid. Tick boxes are found only on grids that support
  actions on multiple rows at once.
- Information in a grid field can be copied to the clipboard by highlighting text in a grid field and clicking Ctrl+C.
- · Hovering over a row will change the row green to show which row the cursor is focused on.
- To open up the details pop-up for a row, or a search page, depending on the functionality of the screen, double click on a row, or select the row and then select an action button from the grid header or the context menu item, if available, by right-clicking.
- Grids use scroll bars to display grids with large quantities of data.
- Grid pages will re-size with the window size.

Figure 2: Using the Management Portal Grids

#### Validating Data Types

In data entry dialogs, fields in which the user is expected to enter certain data types will validate the user input against the expected data type and produce an error if the data entered is not valid. Fields that typically have validation include:

- · email addresses (string fields)
- integers
- strings (alpha-numeric)

Further to this, regular expressions are supported on select entry fields for enrollment (see <u>Certificate Template Operations on page 382</u>).

#### **Pop-up Dialogs**

- When the cursor is focused on a field, the outline of the field will turn purple.
- Active/ available buttons will be bright purple. Inactive/ unavailable buttons will be faded to light purple. When data entered into the panes changes the conditions, the buttons may change between bright and light purple (active/inactive).
- At the bottom of most pop-up dialogs are the Save and Cancel buttons, and possibly other
  actions that can be performed on the data, depending on the purpose of the pane.
- The X in the top right corner is the close option which works like the cancel button.

• Many pop-up panes will have multiple tabs. The tab in which the cursor is focused will be underlined in green. When you point the cursor at another tab, it will temporarily change the underlining to green until you click into the tab.

#### **Under Construction Icon**

The under construction icon will display when an action of a transaction is in process.

Figure 3: Under Construction Icon

#### **Confirmation Message**

Messages appear at the bottom of the screen during processing at times. For example, an operation successful message will appear at the bottom of the screen when a selected action on a transaction is successful.

The create operation was successful

Figure 4: Confirmation Message

#### 2.1.1 Authentication and Authorization

Keyfactor Command can be configured to use either Active Directory as an identity provider or Keyfactor Identity Provider as an identity provider. If you choose to use Active Directory as an identity provider, Keyfactor Command is by default configured to support both Windows integrated authentication and Basic authentication. Windows integrated authentication allows users on domain-joined computers using domain accounts and browsers configured to support integrated authentication to access the Keyfactor Command Management Portal without needing to provide a username or password to authenticate to the Management Portal or Keyfactor API endpoints (from the Keyfactor API Reference and Utility accessed in the same browser session) assuming they have a valid Kerberos ticket. Keyfactor Command can be configured to support only Basic authentication, which requires entry of a username and password to authenticate to the Management Portal or Keyfactor API endpoints. This can be useful in environments where integrated authentication is not practical or desired, such as when users access the Management Portal using different accounts than they use to log on to their computers.

When using Keyfactor Identity Provider as an identity provider, Keyfactor Command uses tokens for authentication and requires users to enter a username and password to authenticate to the Management Portal. To use the Keyfactor API, users need to acquire a token (see *Authenticating to the Keyfactor API* in the *Keyfactor API Reference Guide*).

Keyfactor Command uses a system of security roles and claims to provide access control to the Management Portal as a whole and to the features within it and the Keyfactor API. In order to access

the Management Portal or Keyfactor API, the account you are using to access Keyfactor Command must be a member of one of the groups granted access to the Management Portal during the Keyfactor Command installation and configuration process (see *Install the Main Keyfactor Command Components on the Keyfactor Command Server(s): Administrative Users Tab* in the *Keyfactor Command Server Installation Guide*) or your account must have been granted access either directly or via group membership later through the Management Portal (see <u>Security Roles and Claims on page 623</u>) or with the Keyfactor API (see <u>Security Roles & Identities</u> in the <u>Keyfactor API Reference Guide</u>).

#### 2.1.2 Dashboard

The dashboard, at the top level of the Management Portal, provides you with a quick glance at the status of your PKI. It is a global representation of your PKI and does not filter data based on your access.

#### Risk Header

The top of the page shows a risk header, which is made up of six sticky notes displaying active certificates, expiring and expired certificates, revoked certificates, and certificates with weak keys. The dashboard risk header displays by default and cannot be moved or removed (though it may be hidden with a security setting).

Figure 5: Dashboard Risk Header

The risk header panels are:

· Active Certificates

This value reflects all active certificates in the database, including those with a certificate state of *unknown*, and excludes expired and revoked certificates.

• Certificates Expiring in Less Than 48 Hours

This value includes all active certificates in the database with an expiration date between the current date/time and 48 hours from the current date/time.

Certificates Expiring in Less Than 14 Days

This value includes all active certificates in the database with an expiration date between the current date/time and 14 days (to the minute) from the current date/time. This value includes certificates shown in the *Expiring in < 48 Hours* panel.

Certificates Expired in the Last 7 Days

This value includes all certificates that have expired within the previous 7 days. This is the only panel that includes expired certificates.

Certificates Revoked in the Last 7 Days

This value includes all certificates that have been revoked within the previous 7 days. This is the only panel that includes revoked certificates.

· Certificates with Weak Keys

This value includes all certificates in the database that are deemed to have weak keys. Weak key certificates are those with signature algorithms SHA-1, MD5, RSA key size less than 2048, and ECC key size less than 224.

**Tip:** Access control to the risk header is controlled separately from the dashboard page as a whole, so a user could be granted access to the dashboard but not to the risk header and in this way see a dashboard that did not display the risk header. For more information, see Security Role Permissions on page 633.

#### **Customizable Panels**

A variety of panels are available to add to the dashboard, including:

• A separate panel for each of your certificate authorities (CAs) configured for synchronization can be displayed with graphs showing the activity over the last X weeks (24 by default) and a pie chart showing all active certificates by template. The number of weeks to display is configurable on a panel-by-panel basis. See Dashboard: CA Status on page 12.

**Note**: Any CAs that have not been configured for synchronization will not appear as available for addition on the dashboard, or for reports which require selecting a CA.

- Certificate collections (see <u>Certificate Collection Manager on page 85</u>) can be configured to be included in a bar chart on the Certificate Collection dashboard panel. See <u>Dashboard: Collections on page 13</u>.
- The Certificates by Signing Algorithm panel displays a bar chart showing all active certificates broken down by signing algorithm. The CAs to include in the display are configurable. Both CAs that are currently configured for synchronization and any that were previously synchronized are available for inclusion. Certificates imported into Keyfactor Command via SSL scanning, certificate store inventorying, and manual import are also included and can be filtered out by unchecking the Certificates Not Associated with CA option. See <a href="Dashboard: Certificates by Signing Algorithm on page 14">Dashboard: Certificates by Signing Algorithm on page 14</a>.
- The Recent Certificate Store Jobs panel displays the status of up to ten jobs. Both completed and in progress jobs are included. See Dashboard: Recent Certificate Store Jobs on page 16.
- If you configure certificate revocation list (CRL) or online certificate status protocol (OCSP) locations for monitoring and opt to display them on the dashboard (see <a href="Revocation Monitoring on page 210">Revocation Monitoring on page 210</a>), these will appear with a status on the dashboard Revocation Monitoring panel. See Dashboard: Revocation Monitoring on page 17.

- The comprehensive SSL Endpoints panel includes a grid of changes found in existing SSL endpoints, a grid of endpoints with certificates expiring in the next X days, a pie chart showing SSL endpoints per defined SSL network, and a pie chart showing the results from the last SSL scan broken out by result (e.g. certificate found, connection timed out, connection refused). The number of days for the expiring certificates grid is configurable. See <a href="Dashboard: SSL Endpoints on page 18">Dashboard: SSL Endpoints on page 18</a>.
- The status of SSL discovery and monitoring jobs can be displayed on an orchestrator-by-orchestrator basis on the SSL Orchestrator Job Status panel. The orchestrators to include are configurable. See Dashboard: SSL Orchestrator Job Status on page 19.
- The Number of SSH Keys per Type panel includes SSH keys found on discovery and those issued through the Management Portal and displays as a bar chart broken down by key type. See <u>Dash-board</u>: Number of SSH Keys per Type on page 15.

The panels on the dashboard are displayed in two columns. You can click and drag the dividing line between the two columns to change the width of the columns—for example, a wide left column and a narrower right column. The panels can be rearranged by dragging them up and down a column or from one column to the other. If you've chosen to change the column widths, you can arrange the wider panels in your wider column and the narrower panels in your narrower column.

The selected panels and their arrangement is unique to each user of the Management Portal. Out of the box, in addition to the risk header, the dashboard includes the Collections and Revocation Monitoring panels, so each new user to the dashboard will see these panels.

The latest version of the Logi reporting engine has functionality which avoids a system timeout issue by periodically pinging the IIS session behind the scenes so that the dashboard doesn't time out when the session has been idle. As a result, the dashboard no longer refreshes after 20 minutes, but invokes this new functionality instead. The settings used to control this depend on the **Session State Timeout** and **Session Auto Keep Alive** attribute settings in IIS. For more information on this see:

 $\frac{\text{https://devnet.logianalytics.com/hc/en-us/articles/1500009515942-Manage-Session-Timeout}$ 

#### Add a Panel to the Dashboard Display

To add a panel for display on your dashboard:

1. Click the Add Panel button on the left just below the dashboard risk header.

Figure 6: Click the Dashboard Add Panel Button

2. On the Add Panels dialog, select the panels you wish to display on the dashboard, click **Add** and then click **Done** at the bottom of the dialog.

Figure 7: Add Panels to the Dashboard

#### Rename a Dashboard Panel

The panels displayed on the dashboard may be given user-defined names. To rename a displayed panel:

1. Click the panel **Settings** icon on the right of the panel you wish to rename and then click **Rename**.

Figure 8: Dashboard Panel Settings

2. In the title field of the panel, type a new name. Click away from the field to save.

Figure 9: Type in a New Name for the Panel

**Note**: Only letters, numbers, spaces, and select punctuation marks are supported in the panel name field. Special characters, such as < and > (and therefore HTML markup), are not supported.

#### Remove a Dashboard Panel

To remove a panel from display on your dashboard:

 Click the panel Settings icon on the right of the panel you wish to remove and then click Remove.

Figure 10: Dashboard Panel Settings

2. When prompted, confirm that you are sure that you want to remove the panel.

**Tip:** The **Edit** option only appears on the panel settings menu for selected panels.

#### 2.1.2.1 Dashboard: CA Status

Each CA section of the dashboard includes two line graphs showing issued (top graph) and revoked and failed/denied certificate requests (bottom graph) over the last X weeks or days (24 weeks by default) on the left and a pie chart showing all active certificates by template on the right. To change the number of weeks displayed on the line graphs for all CAs, change the *Weeks of CA Stats* application setting (see <a href="Application Settings: Console Tab on page 603">Application Settings: Console Tab on page 603</a>). To change the number of weeks or days displayed on the line graph on a CA-by-CA basis, click the panel **Settings** icon for the selected CA and choose **Edit**. A maximum of 52 weeks or 30 days may be configured when setting the time frame on a CA-by-CA basis.

The panel is interactive in a number of ways:

- Hover over a point on a line graph to see details for that point.
- Click on a point on a line graph to be taken to a new window with the certificate search page populated by the query of the selected CA and date.
- Click on a legend (e.g. Revoked) below a line graph to toggle add/remove that line from the chart.
- Click one of the labels below the pie chart to toggle add/remove that segment of the pie from the chart. This can be helpful, for example, if you remove a template that makes up the bulk of the chart, allowing you to just focus on the remaining templates (and making these pie segments bigger and easier to click on).
- Hover over a number for, or section of, the pie chart to see the template name associated with that section of the pie chart. This is the number of active certificates for that template.
- Click on a number for, or section of, the pie chart to be taken to a new window with the certificate search page populated by the query of the selected CA and template.

A status indicator appears at the top of the CA section showing when the CA was last contacted. Click the **Hide** button to minimize the display. Click the panel **Settings** icon to remove or rename the panel or change the comparison date for the display (see <u>Dashboard on page 6</u>). Data for the CA sections of the dashboard is generated from certificates retrieved during CA synchronization tasks (see Certificate Authorities on page 350).

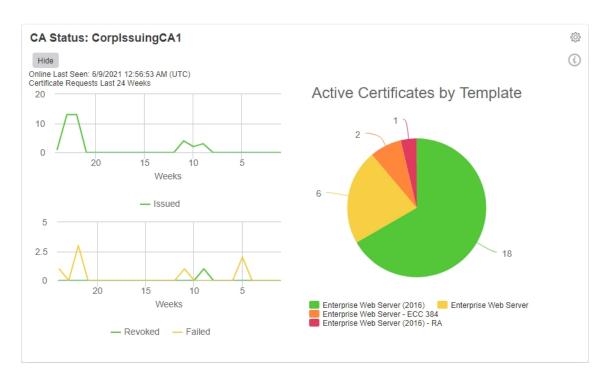

Figure 11: Dashboard CA Snapshot

#### 2.1.2.2 Dashboard: Collections

If you opt to include any certificate collections for display on the dashboard (see <u>Certificate Collection Manager on page 85</u>), you will see the data on the Collections dashboard panel. This panel shows a bar representing the total number of active, expired and revoked certificates for each certificate collection configured for dashboard display. Hover over a bar to see the number of certificates in the collection. Click on a bar to open the certificate search page in a new window filtered for that certificate collection.

**Note:** The collections dashboard widget will only display the first 25 collections alphabetically.

**Tip:** If you **Save** a new certificate collection, or **Save** a change to an existing certificate collection, that change will be immediately reflected in the collection data used to display certificate collections on dashboards and reports. The data used by the dashboards and reports is stored in an intermediate table that is updated immediately. It will also continue to be updated periodically (approximately every 20 minutes by default as configured by the *Dashboard Collection Caching Interval* application setting) by the Keyfactor Command Service (see Application Settings: Console Tab on page 603).

Click the **Hide** button to minimize the display. Click the panel **Settings** icon  $\P$  to remove or rename the panel or change the comparison date for the display (see <u>Dashboard on page 6</u>).

Figure 12: Dashboard Certificate Collections

#### 2.1.2.3 Dashboard: Certificates by Signing Algorithm

The Certificates by Signing Algorithm panel on the dashboard shows a bar chart of all active certificates synchronized to Keyfactor Command from a Microsoft CA or Keyfactor CA gateway or imported via SSL scanning, certificate store inventorying, or manual import broken down by signing algorithm. Hover over a bar to see the number of active certificates in the category. By default, all certificates in the Keyfactor Command database are included. To include only selected CAs or gateways, click the panel **Settings** icon and choose **Edit**. In the Edit dialog, select the CAs you wish to include in the panel. To filter out certificates brought into the database via SSL scanning, certificate store inventorying, and manual import, select specific CAs and uncheck the *Certificates Not Associated with CA* option.

Click the **Hide** button to minimize the display. Click the panel **Settings** icon to remove or rename the panel or change the comparison date for the display (see <u>Dashboard on page 6</u>).

Figure 13: Dashboard Certificates by Signing Algorithm

#### 2.1.2.4 Dashboard: Number of SSH Keys per Type

The Number of SSH Keys per Type panel on the dashboard shows a bar chart of all SSH keys in the Keyfactor Command database. The chart includes both managed keys (those generated within Keyfactor Command using My SSH Key (see My SSH Key on page 532) or the service account key page (see Service Account Keys on page 543) and unmanaged keys (see Unmanaged SSH Keys on page 557). Hover over a bar to see the number of SSH keys in the category.

Click the **Hide** button to minimize the display. Click the panel **Settings** icon to remove or rename the panel or change the comparison date for the display (see <u>Dashboard on page 6</u>).

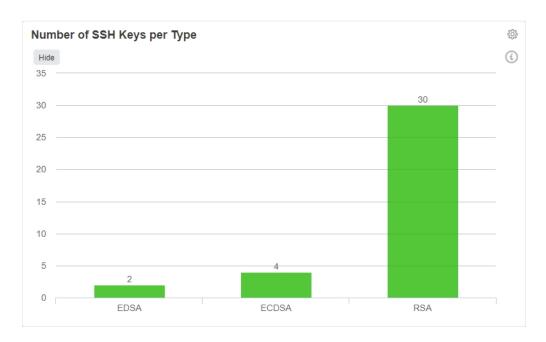

Figure 14: Dashboard SSH Keys per Type

#### 2.1.2.5 Dashboard: Recent Certificate Store Jobs

The Recent Certificate Store Jobs panel on the dashboard includes a grid showing the most recent job history for certificate stores. Both completed (successful or not) and in progress jobs are included. The grid includes the orchestrator name, the target for the job (which in most cases includes the host name and the certificate store name), the job start date, the job type (e.g. inventory or management for an IIS or F5 store), and color-coded results (errors appear in red) for the job.

Click on the name of the orchestrator in the grid to be taken to the orchestrator job history page with the query populated by the selected orchestrator.

To include only jobs that started on or after a selected date, click the panel **Settings** icon and choose **Edit**. In the Edit dialog, either enter a comparison date or use the calendar picker to select a date. Only jobs with a starting date on or after this date will be shown. A maximum of ten jobs are shown.

Click the **Hide** button to minimize the display. Click the panel **Settings** icon to remove or rename the panel or change the comparison date for the display (see Dashboard on page 6).

Figure 15: Dashboard Recent Certificate Store Jobs

#### 2.1.2.6 Dashboard: Revocation Monitoring

The Revocation Monitoring panel on the dashboard shows each configured CRL and OCSP location (if they have been configured to appear on the dashboard) with the path to the CRL or OCSP, the publication, next publish date, and expiration dates of the CRLs (these aren't relevant for OCSPs) and the status of the CRL or OCSP. The status for a CRL will show *Warning* if the expiration date of the CRL is within the warning period as defined by the number of weeks, days, or hours configured in the *Show on Dashboard* setting (see <u>Revocation Monitoring Location Operations on page 211</u>). For example, if you had a CRL that expired on June 30 and configured the warning period to 15 days before expiration, the Warning status would begin to appear on the dashboard for that CRL on June 15.

Some columns allow for sorting in ascending or descending order by clicking the column heading to toggle sort order. Click the **Hide** button to minimize the display. Click the panel **Settings** icon to remove or rename the panel or change the comparison date for the display (see <u>Dashboard on page 6</u>).

Figure 16: Dashboard Revocation Monitoring Status

#### 2.1.2.7 Dashboard: SSL Endpoints

The comprehensive SSL Endpoints panel includes several components:

- The Changes Found to Existing Endpoints grid displays up to ten SSL endpoints for which a change was found in the most recent scan from the previous scan status. The grid includes the endpoint address, scan time, and both the previous and current endpoint status. This grid only displays if there are endpoints that have been changed.
- The Endpoints Expiring in the Next X Days grid displays up to ten SSL endpoints with certificates expiring in the next X days. This grid only displays if there are endpoints that meet that criteria. If there are more than ten to display, the certificates expiring soonest are displayed. Out of the box, the number of days is configured to 30. To change the number of days, click the panel **Settings** icon, choose **Edit**, enter a number of days, and click **Done**. To clear the custom number of days and return to the default, click the panel **Settings** icon, choose **Edit**, clear the days field, and click **Done**. The grid includes the network name, the endpoint address, the certificate expiration date, and the certificate common name, if any.
- The Endpoints per Network pie chart shows discovered SSL endpoints broken down by SSL network. All discovered endpoints are included. This includes endpoints at which a certificate is currently being found, endpoints at which a certificate was found in the past but is no longer found, and endpoints that responded in some way on scan but did not present a certificate. Click on a section of the pie chart to be taken to the SSL Discovery Results page. Click any of the labels below the pie chart to toggle add/remove that segment of the pie from the chart.
- The Network Endpoint SSL Scanning Results pie chart shows the results from the most recent SSL scan (discovery or monitoring) broken out by result (e.g. certificate found, connection timed out, connection refused). Click on a section of the pie chart to be taken to the SSL Discovery Results page. Click any of the labels below the pie chart to toggle add/remove that segment of the pie from the chart. This can be helpful, for example, if you remove the certificate found section, allowing you to just focus on any errors (and making the error pie segments bigger and easier to click on).

Click the **Hide** button to minimize the display. Click the panel **Settings** icon to remove or rename the panel or change the comparison date for the display (see Dashboard on page 6).

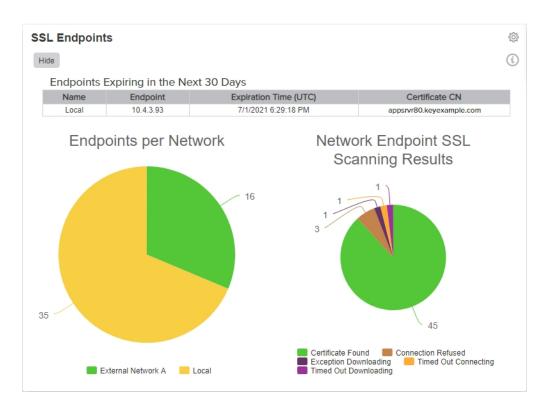

Figure 17: Dashboard SSL Endpoints

#### 2.1.2.8 Dashboard: SSL Orchestrator Job Status

The SSL Orchestrator Job Status panel on the dashboard displays a grid showing the results of the two most recent SSL jobs for each active Keyfactor Universal Orchestrator with the SSL capability in the configured orchestrator pool (see Orchestrator Pools Definition on page 471). Both jobs in progress and completed jobs are included. The grid includes the names of the orchestrators in the selected pool(s), the job type, job start date and time, color-coded results (errors appear in red), and color-code status (jobs in progress are yellow). To change the orchestrator pools included in the display, click the panel **Settings** icon, choose **Edit**, select the desired orchestrator pools, and click **Done**.

Click on the name of an orchestrator in the grid to be taken to the orchestrator job history page with the query populated by the selected orchestrator.

Click the **Hide** button to minimize the display. Click the panel **Settings** icon to remove or rename the panel or change the comparison date for the display (see Dashboard on page 6).

Figure 18: Dashboard SSL Orchestrator Job Status

#### 2.1.3 Certificate Search and Collections

The Keyfactor Command database can include certificates from many locations—including certificates synchronized from your Microsoft CAs in both the primary forest and alternate forests, certificates synchronized from your EJBCA CAs, certificates synchronized from cloud-based certificate vendors via the Keyfactor certificate gateways, certificates automatically imported based on configured SSL endpoint locations (see <u>SSL Discovery on page 454</u>), certificates imported from certificate stores (see <u>Certificate Stores on page 409</u>), and manually imported certificates (see <u>Add Certificate on page 74</u>). The Certificate Search function allows you to query the database for certificates from any available source. You do not need to specify the source as part of the query.

A specific certificate search may be saved as a collection, which can then be revisited without needing to enter the search selections again. The saved collection can then be referenced from other parts of the Management Portal (e.g. expiration alerts, the dashboard, and select reports). Certificate collections may be added to the *Certificates* menu of the Management Portal for quick access. Several default certificate collections are created in new installations. For more information, see Certificate Collection Manager on page 85.

**Note:** The options shown and described in this section are available to full administrative users of the Management Portal. Users with limited access to the Management Portal will not see all the options (e.g. the recover buttons may not appear) and will see some slightly different buttons (e.g. the edit buttons shown may say *view* instead of *edit*).

#### 2.1.3.1 Certificate Details

The cornerstones of the Keyfactor Command Management Portal are the Certificate Search and the Certificate Details pages. The Certificate Details page includes a comprehensive set of details about each certificate managed by Keyfactor Command. To access a certificate's details, double-click on a row of the certificate search grid, or highlight a row, right click and select **Edit** (**Display** for users with only Read permissions) from the action menu (see <u>Certificate Search Page on page 35</u>).

The following action buttons are conveniently located at the top of the Certificate Details page for users with the appropriate permissions: **Revoke**, **Download**, **Renew**. See <u>Certificate Operations on page 46 for more information on these actions.</u>

#### **Content Tab**

The Content tab shows the certificate attributes from the CA (Active Directory in the case of a Microsoft CA). These fields are not editable. The list of Subject Alternative Names (SANs) and SAN count are also included on this tab. For an ECC certificate, the elliptic curve algorithm is included on this tab.

Tip: Double-click any field on this dialog to open a pop-up showing just that detail.

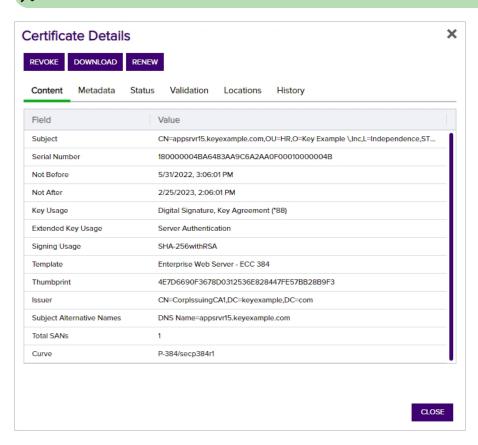

Figure 19: Certificate Details: Content Tab

#### Metadata Tab

The Metadata tab displays all metadata fields created for your Keyfactor Command implementation and shows any data in fields that have been populated with values specific to the certificate. Depending on the metadata type, these fields appear as text boxes, radio buttons, drop-downs, date fields, table or large text fields.

For users with edit permissions, on date fields a small popup calendar will appear that will allow you to select a date and will properly format it for you. You may edit values for any metadata fields to update the data at any time. You may also update multiple certificates' metadata with the same data by selecting multiple certificates from the certificates grid. Required fields will be marked with

\*Required next to the field label. See Certificate Metadata on page 712 for information on this functionality.

Tip: The order of the metadata fields as they appear on this dialog is configurable using the certificate metadata display order option (see Sorting Metadata Fields on page 717).

Figure 20: Certificate Details: Metadata Tab

The email metadata type will display a grid with the list of email addresses associated with the certificate(s). Grid action options of **Add**, **Edit** and **Delete** are included.

Figure 21: Email Type Metadata

## **Status Tab**

The status tab displays some additional information about the certificate (see <u>Table 1: Status Tab Descriptions</u>).

The fields on this tab cannot be edited.

Tip: Double-click any field on this dialog to open a pop-up showing just that detail.

Figure 22: Certificate Details: Status Tab

Table 1: Status Tab Descriptions

Field	Description	
Certificate ID	The Keyfactor Command reference ID for the certificate, which can be useful when referring to the certificate using API methods.	
CA Record ID	The ID of the certificate in the CA (this has replaced CARequestID).	
Certificate State	<ul> <li>The state of the certificate.</li> <li>Unknown (0)—This certificate entered the system in a manner other than a CA sync, so no status from a CA has been reported.</li> <li>Active (1)—The "normal" state for certificates brought in via CA sync. The certificate has not been revoked.</li> <li>Note: Here we mimic the behavior of the Microsoft CA, which does not have a status for Expired, so certificates continue to be listed as Active or Revoked (as appropriate) after they expire.</li> </ul>	
	<ul> <li>Revoked (2)—The certificate has been revoked.</li> <li>Failed (4)—The certificate has been denied approval.</li> <li>Pending (5)—The certificate is awaiting approval.</li> <li>Certificate Authority (6)—The certificate synced in from a CA sync that is indicated to be that CA's own certificate.</li> <li>Parent Certificate Authority (7)—The certificate synced in from a CA sync that is indicated to be the certificate of a CA further up the chain.</li> <li>Waiting for External Validation (8)—The certificate is pending, awaiting approval outside of Keyfactor Command. Generally, the certificate would have been added through one of the Keyfactor Command CA gateways using an EV certificate type.</li> </ul>	
Revocation Effective Date	If the certificate is revoked, the date it was revoked will be displayed here.	
Revocation Reason	If the certificate is revoked, the reason will be displayed here. This is shown as a numeric value, which will be one of:  • 0 — Unspecified  • 1 — Key Compromised  • 2 — CA Compromised  • 3 — Affiliation Changed  • 4 — Superseded  • 5 — Cessation of Operation  • 6 — Certificate Hold  • 999 — Unknown	

Field	Description	
	See Revoke on page 71 for more information about revoking certificates.	
Archive Key	If true, the certificate has a private key archived on the Microsoft CA to support CA key recovery. This flag is not an indicator for whether the certificate has a private key stored in Keyfactor Command.	
	Tip: CA-level key recovery is supported for Microsoft CAs to allow recovery of private keys for certificates enrolled outside of Keyfactor Command. CA-level key archiving is not supported for enrollments done through Keyfactor Command. CA-level key recovery is not supported for EJBCA CAs. For enrollments done through Keyfactor Command for either Microsoft or EJBCA CAs, use Keyfactor Command private key retention (see <a href="Details Tab on page 388">Details Tab on page 388</a> ).	
Principal Name	The user principal name (UPN) contained in the subject alternative name (SAN) field of the certificate, if present (e.g. username@keyexample.com).	
Requester Name	The name of the requester in DOMAIN\User format.	

## Validation Tab

This tool will report on the certificate validity based on the criteria defining the status of an X509 chain shown in <u>Table 2: Validation Tab Descriptions</u>. This tab replaces the former **Validate** action from the certificate search grid. An alert symbol will show on the tab header if one or more tests have a result of *Fail*.

**Tip:** See <u>Certificate Validation Errors on page 827</u> for assistance troubleshooting validation errors.

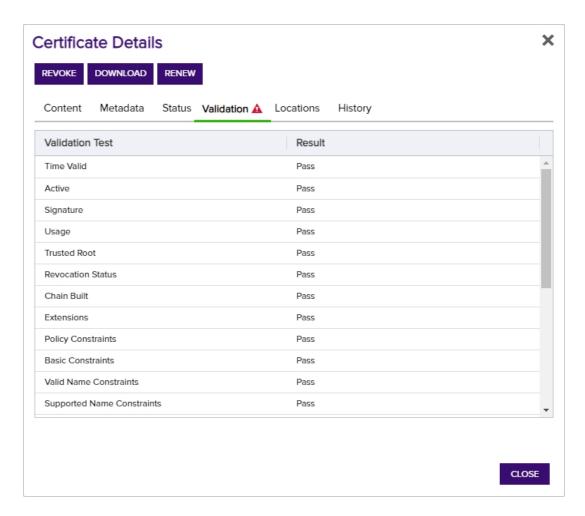

Figure 23: Certificate Details: Validation Tab

Table 2: Validation Tab Descriptions

Validation Test	Keyfactor API Equivalent <sup>1</sup>	Definition
Time Valid	NotTimeValid	A value of <i>Pass</i> indicates that the certificate time value is valid. A time can appear invalid ( <i>Fail</i> ) for a certificate that has expired.
Active	Revoked	A value of <i>Pass</i> indicates that the X509 certificate chain is valid for the certificate and contains no revoked certificates or errors.
Signature	NotSignatureValid	A value of <i>Fail</i> indicates that the X509 certificate chain is invalid as a result of an invalid certificate signature.
Usage	NotValidForUsage	A value of <i>Fail</i> indicates that the X509 certificate chain is invalid as a result of an invalid key usage.
Trusted Root	UntrustedRoot	A value of <i>Fail</i> indicates that the X509 certificate chain is invalid as a result of an untrusted root certificate.
Revocation Status	RevocationStatusUnknown	A value of <i>Pass</i> indicates that the revocation status can successfully be determined for the certificate. This may be the result of successful access to online certificate revocation lists (CRLs) and, if configured, authority information access (AIA) endpoints.
Chain Built	Cyclic	A value of <i>Pass</i> indicates that the certificate chain for the certificate could successfully be built.
Extensions	InvalidExtension	A value of <i>Fail</i> indicates that the X509 certificate chain is invalid as a result of an invalid extension.
Policy	InvalidPolicyConstraints	A value of Fail indicates that the X509 certi-

 $<sup>^1</sup>$ The parameter names for results returned by the Keyfactor API GET /Certificates/ $\{id\}$ /Validate method.

Validation Test	Keyfactor API Equivalent <sup>1</sup>	Definition
Constraints		ficate chain is invalid as a result of an invalid policy constraint.
Basic Constraints	InvalidBasicConstraints	A value of <i>Fail</i> indicates that the X509 certificate chain is invalid as a result of an invalid basic constraint.
Valid Name Constraints	InvalidNameConstraints	A value of <i>Fail</i> indicates that the X509 certificate chain is invalid as a result of an invalid name constraint.
Supported Name Constraints	HasNotSupportedNameConstraint	A value of <i>Fail</i> indicates that a name constraint for the certificate is unsupported or that the certificate has no supported name constraints.
Defined Name Constraints	HasNotDefinedNameConstraint	A value of <i>Fail</i> indicates that a name constraint for the certificate is undefined.
Permitted Name Constraints	HasNotPermittedNameConstraint	A value of <i>Fail</i> indicates that a name constraint for the certificate is impermissible.
Excluded Name Constraints	HasExcludedNameConstraint	A value of <i>Fail</i> indicates that a name constraint for the certificate has been excluded.
Full Chain	PartialChain	A value of <i>Pass</i> indicates that the certificate chain for the certificate could successfully be built up to the root certificate.
CTL Time Valid	CtlNotTimeValid	A value of Fail indicates that the certificate trust list (CTL) is invalid because of an invalid time value (e.g. the CTL has expired).
CTL Signature Valid	CtlNotSignatureValid	A value of <i>Fail</i> indicates that the certificate trust list (CTL) contains an invalid signature.

 $<sup>^1</sup>$ The parameter names for results returned by the Keyfactor API GET / Certificates/ $\{id\}$ /Validate method.

Validation Test	Keyfactor API Equivalent <sup>1</sup>	Definition
CTL Usage Valid	CtlNotValidForUsage	A value of <i>Fail</i> indicates that the certificate trust list (CTL) is not valid for this use.
Strong Signa- ture	HasWeakSignature	A value of <i>Pass</i> indicates that the certificate has been signed with a secure hashing algorithm. A value of <i>Fail</i> can indicate that a hashing algorithm of MD2 or MD5 was used for the certificate.
CRL online	OfflineRevocation	A value of <i>Pass</i> indicates that the online certificate revocation list (CRL) the chain relies on is available.
Chain Policy	NolssuanceChainPolicy	A value of <i>Pass</i> indicates that there is either no certificate policy by design in the certificate or that if a group policy has specified that all certificates must have a certificate policy, the certificate policy exists in the certificate.
No Explicit Distrust	ExplicitDistrust	A value of <i>Pass</i> indicates that the certificate is not explicitly distrusted.
Critical Extensions	HasNotSupportedCriticalExtension	A value of <i>Pass</i> indicates that the certificate has a critical extension that is supported or has no critical extensions.

## **Locations Tab**

If you have added the certificate to any certificate store location(s) a number will appear in the **Count** column on the corresponding **Location Type** row. Users with limited permissions will only see locations for types of certificate stores to which they have been granted permissions either globally or via certificate store containers (see <u>Container Permissions on page 630</u>). Click the count number for more details regarding this certificate's location. See <u>Add to Certificate Store on page 46</u> for more information. The *Total Cert Store Locations* appears at the end of the list. Clicking on the total will open a dialog with the list of locations with the columns: Store Path, Store Machine, Alias, IPAddress, Port, and Agent Pool which will be populated depending on the details of the individual stores.

**Note:** The SSL network name is searchable with certificate search and also appears in the location details grid of the certificate details, if the certificate was found during an SSL scan.

<sup>&</sup>lt;sup>1</sup>The parameter names for results returned by the Keyfactor API *GET / Certificates / {id} / Validate* method.

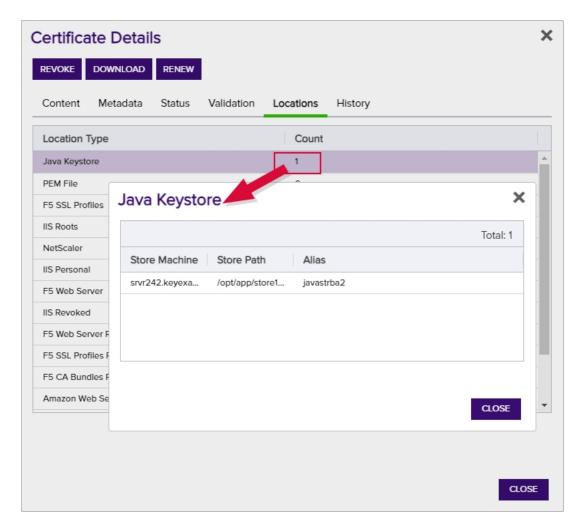

Figure 24: Location Details

Figure 25: Total Certificate Store Location Details

## **History Tab**

History about a certificate is recorded in the Keyfactor Command database for the following types of activities (see also Audit Log on page 718):

- Initial Import—A history entry is made on import via CA synchronization, SSL synchronization, certificate store synchronization or manual import.
- Certificate Enrollment—A history entry is made when a PFX or CSR enrollment is completed through the Keyfactor Command Management Portal. The source of the request (PFX or CSR) is indicated.
- Revocation—A history entry is made each time a certificate is revoked, so if a certificate is revoked multiple times, there will be multiple history entries.
- Key Recovery—A history entry is made each time the key for a certificate is recovered, so if the
  key for a given certificate is recovered multiple times, there will be multiple history entries. This
  type of record is generated when the private key for a certificate is downloaded from the
  Keyfactor Command database or when a private key is recovered from a CA using the CA's key
  recovery mechanism.
- Certificate Store Additions and Removals—A history entry is made each time a certificate is added to a certificate store or removed from a certificate store. These entries reference the specific certificate store type and whether the operation was an addition or removal—Add ([store type]) and Remove ([store type])—and include details in the certificate history comments.
- Certificate Renewals—A history entry is made each time a certificate is renewed or reissued.
   The certificate renewal history record appears on both the old certificate (renewed from) and the new renewed certificate.
- Certificate Store Inventory Discoveries—A history entry is made each time an inventory of a
  certificate store notices that a certificate that was in a certificate store no longer is or that a
  new certificate has appeared in the certificate store. These entries are referenced as Certificate Appeared ([store type]) and Certificate Disappeared ([store type]) with details in the certificate history comments.
- SSL Endpoint Inventory Discoveries—A history entry is made each time an inventory of an SSL
  endpoint notices that a certificate that was at an endpoint no longer is or that a new certificate
  has appeared at an endpoint during a monitoring task. These entries are referenced as Certificate Appeared (SSL Sync) and Certificate Disappeared (SSL Sync) with details in the certificate history comments.
- Metadata Updated—A history entry is made each time a metadata field is updated for the certificate. The changed data will be recorded in the Comment field.

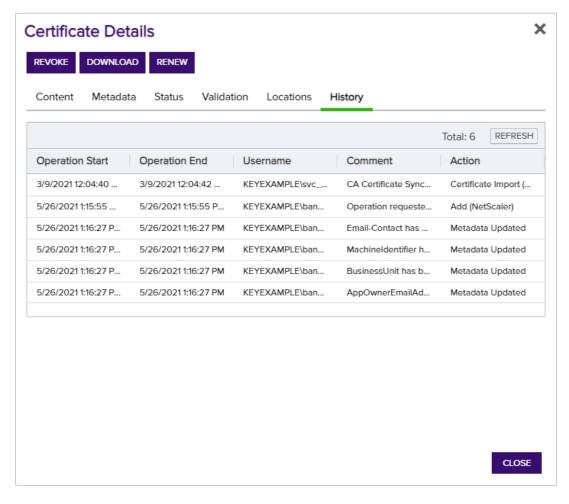

Figure 26: Certificate Operation: Certificate History Tab

**Tip:** Double-click a row on the History grid to see the content of that row in a more readable pop-up.

Figure 27: Certificate Operation: Certificate History Detail

# 2.1.3.2 Certificate Search Page

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an *is null* or *is not null* comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

Each query consists of three parts:

## **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

ArchivedKey	КеуТуре
The certificate's archived key has been encrypted and saved to the Keyfactor Command database	The referenced certificate key type. Supported types are:
(true/false).	• Unknown
	• RSA
CertId	• DSA
Numeric matches with the Keyfactor Command	• ECC
reference ID for the certificate.	• DH
CA	• Ed448

Complete or partial matches with the certificate issuing CA logical name.

#### CertState

The certificate state; Unknown, Active, Revoked, CertificateAuthority, ParentCertificateAuthority.

#### CertStoreFQDN

Complete or partial matches with the fully qualified domain name of the computer hosting one or more certificate stores.

This field has an alias of JavaKeystoreFQDN that may be used when querying the field from the Keyfactor API.

### CertStorePath

Complete or partial matches on the full path to a certificate store—e.g. /opt/application/mystore.jks or c:\program files\application\mystore.jks.

This field has an alias of *JavaKeystorePath* that may be used when querying the field from the Keyfactor API.

#### CertStoreContainer

Certificate is in a certificate store that is included in the container criteria indicated.

## CN

Complete or partial matches with the certificate common name.

This field has an alias of *IssuedCN* that may be used when querying the field from the Keyfactor API.

### DN

Complete or partial matches with the certificate distinguished name.

This field has an alias of *IssuedDN* that may be used when querying the field from the Keyfactor API.

#### ExpirationDate

Certificate expiration before, after, or on a

- Ed25519
- Dilithium2
- Dilithium3
- Dilithium5

#### KeyUsage

Certificate includes or doesn't include (or is null or not null for) the referenced key usage. Supported key usages are:

- CRLSign
- DataEncipherment
- DecipherOnly
- · DigitalSignature
- EncipherOnly
- KeyAgreement
- KeyCertSign
- KeyEncipherment
- NonRepudiation

## NetBIOSPrincipal

Complete or partial matches with the certificate principal name in NetBIOS format (DOMAIN\username). Supports the %ME% token (see <a href="Advanced Searches">Advanced Searches</a> on page 41).

This field has an alias of *PrincipalName* that may be used when querying the field from the Keyfactor API.

## NetBIOSRequester

Complete or partial matches with the certificate requester's name in NetBIOS format (DOMAIN\username). Supports the %ME% token (see Advanced Searches on page 41).

This field has an alias of *RequesterName* that may be used when querying the field from the Keyfactor API.

### OU

Complete or partial matches with the certificate organizational unit.

specified date. Supports the %TODAY% token (see Advanced Searches on page 41). Be sure to check the *Include Expired* checkbox to view expired certificates.

This field has an alias of *NotAfter* that may be used when guerying the field from the Keyfactor API.

#### EKU

Complete or partial matches with the certificate template OID.

### **EKUName**

Complete or partial matches with the certificate template Name.

### HasPrivateKey

Certificate private key encrypted and stored in the Keyfactor Command database (true/false).

#### ImportDate

The certificate imported to Keyfactor Command before, after, or on a specified date.

### IssuedDate

Certificate issuance before, after, or on a specified date. Supports the %TODAY% token (see Advanced Searches on page 41).

This field has aliases of *NotBefore* and *EffectiveDate* that may be used when querying the field from the Keyfactor API.

### IssuerDN

Complete or partial matches with the certificate issuer's distinguished name.

## KeyfactorRequestId

Numeric matches with the Keyfactor Command reference ID for the certificate request.

#### KeySize

Complete or partial matches with the certificate

### PublicKey

Exact matches with the certificate public key in hexadecimal or base64 format.

#### RevocationDate

Certificate revocation before, after, or on a specified date, or is null or not null. Be sure to check the *Include Revoked* checkbox to view revoked certificates. Supports the %TODAY% token (see Advanced Searches on page 41).

This field has an alias of *RevocationEffDate* that may be used when querying the field from the Keyfactor API.

#### Revoker

Complete or partial matches with the name of the user (DOMAIN\username format) who revoked the certificate. Be sure to check the *Include Revoked* checkbox to view revoked certificates.

### RFC2818Compliant

Certificate is compliant with RFC 2818 (contains a DNS SAN) (true/false).

## SelfSigned

Certificate is self-signed (true/false).

#### SerialNumber

Complete, or starts/ends with, or null/not null matches with the certificate serial number.

## SigningAlgorithm

Complete or partial matches with the certificate signing algorithm.

#### SSLDNSName

Complete or partial matches with the DNS name resolved for an SSL endpoint.

#### **SSLIPAddress**

key size.

This field has an alias of *KeySizeInBits* that may be used when querying the field from the Keyfactor API.

Complete, or starts/ends with, or null/not null matches with the IP address defined for an SSL endpoint.

This field has an alias of *SslHostName* that may be used when querying the field from the Keyfactor API.

#### SSLNetworkName

Complete, or starts/ends with, or null/not null matches with the network name under which an SSL endpoint was found.

#### **SSLPort**

Complete or partial numeric matches with the port number defined for an SSL endpoint.

#### SAN

Complete or partial matches with the certificate subject alternate name(s).

#### TemplateDisplayName

Complete or partial matches with the certificate template display name.

This field has an alias of *TemplateName* that may be used when querying the field from the Keyfactor API.

## TemplateShortName

Complete or partial matches with the certificate template name.

### Thumbprint

Complete or partial matches with the certificate thumbprint value.

You can also do queries based on user-defined metadata fields (see <u>Certificate Metadata on</u> page 712).

## Comparison Operator

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the

equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Contains (-contains)
- Does not contain (-notcontains)

Most date and integer fields support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Is less than (-It)
- Is less than or equal to (-le)

Most Boolean (true/false) fields support:

- Is equal to (-eq)
- Is not equal to (-ne)

- Starts with (-startswith)
- Ends with (-endswith)
- Is null (-eq NULL)
- Is not null (-ne NULL)
- Is greater than (-gt)
- Is greater than or equal to (-ge)
- Is null (-eq NULL)
- Is not null (-ne NULL)
- Is null (-eq NULL)
- Is not null (-ne NULL)

# **Comparison Value**

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

- Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.
- Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options. The results grid includes these fields:

### Issued DN

The distinguished name of the certificate subject.

## **Import Date**

The date the certificate was imported to Keyfactor Command. This field will auto populate on any new imports/enrollments of certificates. On an upgrade, this field will be populated in existing certificates from the certificate operation history.

## **Principal Name**

The identity that the certificate represents. The principal name field is populated during certificate synchronization by the user principal name (UPN) extracted from Active Directory if there is a principal name in the certificate subject alternative name (SAN).

# Requester

The user or entity that requested the certificate.

## **Effective Date**

The date the certificate was issued or became active.

## **Expiration Date**

The date the certificate expires.

### **Issued CN**

The common name of the certificate subject.

### **Issuer DN**

The distinguished name of the certificate issuer.

## **Certificate Template**

The short name of the template used to issue the certificate.

### Locations

The server(s), if any, that the certificate is hosted on (e.g. for SSL certificates). If the certificate is found on multiple servers, this field will show the number of servers on which it was found and the location type (e.g. 4 SSL or 6 JKS). The specific server names can be found in the certificate details.

## **Key Type**

The key type of the certificate.

# **Key Size**

The key size of the certificate.

## **Certificate State**

The certificate state options are:

- Unknown (0)
- Active (1)
- · Revoked (2)
- Failed (4)
- Pending (5)
- · Certificate Authority (6)
- Parent Certificate Authority (7)

#### Certificate Search 9

Clicking "Advanced" allows you to build a query based on multiple criteria using AND/OR logic. Select a field and comparison operator in the drop-downs and then enter a comparison value. Click "Insert" to add the search criteria to the query field below the selection fields. Each time you click the "Insert" button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parenthieses around portions of the query along with AND/OR to an OR if desired. You can use parenthieses around portions of the query along with AND/OR to an OR you meaning.

Figure 28: Certificate Search

The search results can be sorted by clicking on a column header in the results grid for every column (except Certificate Locations, Key Type, and Certificate State). Click the column header again to reverse the sort order. The grid columns can be arranged in any order desired by click-holding and

dragging the header of the column you wish to move. The column widths may be adjusted by click-holding and dragging the line separating two column headers.

You can click the **Include Revoked** and/or **Include Expired** buttons at the top of the results grid to toggle inclusion of revoked or expired certificates in the results. By default they are excluded.

The rest of the buttons at the top of the display grid are used to interact with the certificates displayed in the results grid. Some buttons are grayed out until you click on a grid row. Other certificate functions are available on the right-click menu. To open the right-click menu, highlight a row in the results grid and right-click. You can also double-click a certificate row in the results grid to open the Certificate Details (see Certificate Details on page 20).

To select a single row in the grid, click to highlight it and then select an operation from either the top of the grid or the right-click menu. Some of the certificate operations support action on multiple certificates at once. To select multiple rows, hold down the CTRL key and click each row on which you would like to perform an operation, or tick the check box next to the row. Then select an operation from the top of the grid. The right-click menu supports limited operations on the multiple certificates.

### **Advanced Searches**

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

## **Multiple Criteria**

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click **Insert** to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

**Note**: Multiple *OR* queries can be slow due to the nature of the query not being indexed and potentially requiring multiple queries of the database. To mitigate this, we suggest you create a collection for the subset of certificates, using the *OR* statement as needed, then perform a

search starting with that collection and adding any additional conditions using advanced search from the search page. See Saving Search Criteria as a Collection on the next page.

In addition to the options available in the query builder, three special values can be used in selected searches by typing them in directly:

## • %TODAY%

Use the TODAY special value in place of a specific date in date queries. This option supports math operations, so you can use TODAY-10 or TODAY+30. The built-in *Certificates Expiring in 7 Days* collection uses this special value (see Certificate Collection Manager on page 85).

**Example:** Create a certificate search of IssuedDate -ge "%TODAY-7%" and save it as a collection called *Certificates Issued in the Last Week*. Create another certificate search of ExpirationDate -It "%TODAY+60%" and save it as a collection called *Certificates Expiring in the Next 60 Days*. This allows you to have saved collections containing a comparison date without having to update the date in the collection.

## %ME%

Use the ME special value in place of a specific domain\user name in queries that match a domain\user name. The built-in *My Certificates* collection uses this special value (see <u>Certificates</u> Collection Manager on page 85).

**Example:** Create a certificate search of NetBIOSRequester -contains "%ME%" and save it as a collection. Multiple users can now use this same collection to search for all the certificates on which they were the requester in the current domain.

**Note**: Certificate collections saved using the %ME% value are *not* supported for use in reports or on the dashboard.

## %ME-AN%

Use the ME-AN special value in place of a specific user name excluding the domain. This is beneficial in environments with multiple domains where there is a desire to query for a user's certificates even if they were requested across multiple domains.

**Example:** Create a certificate search of NetBIOSRequester -contains "%ME-AN%" and save it as a collection. Multiple users can now use this same collection to search for all the certificates on which they were the requester, regardless of domain.

**Note:** Certificate collections saved using the %ME-AN% value are *not* supported for use in reports or on the dashboard.

**Important:** The special query options of %TODAY%, %ME%, and %ME-AN% are only supported in uppercase. Lowercase equivalents (e.g. %me%) cannot be substituted.

To build a deep link with your search criteria, begin with the following URL (where KEYFACTOR\_ SERVER\_FQDN is the FQDN of your Keyfactor Command administration server):

https://KEYFACTOR\_SERVER\_FQDN/key-factorportal/CertificateCollection/Query?query=YOUR\_URL\_ENCODED\_QUERY

Your Management Portal may have been configured to use HTTP rather than HTTPS.

Replace YOUR\_URL\_ENCODED\_QUERY with your search criteria as built using the advanced search. The search criteria needs to be URL encoded, so, for example, spaces need to be replaced with %20 and quotation marks with %22. However, many modern browsers will automatically do this for you. A deep link using part of the example search shown above would look something like this without URL encoding:

https://keyfactor.keyexample.com/keyfactorportal/CertificateCollection/Query?query=CN-contains "appsrvr"

And with URL encoding, like this:

https://key-

factor.keyexample.com/keyfactorportal/CertificateCollection/Query?query=CN%20-contain-s%20%22appsrvr%22

**Tip:** Click the help icon (②) next to the page title to open the embedded web copy of the *Keyfactor Command Documentation Suite* to this section.

You can also find the help icon at the top of the page next to the **Log Out** button. From here you can choose to open either the *Keyfactor Command Documentation Suite* at the home page or the *Keyfactor API Endpoint Utility*.

## Saving Search Criteria as a Collection

To save your search criteria as a certificate collection:

1. Click the Save button.

Figure 29: Save Certificate Collection

- 2. In the Save Certificate Search dialog, enter a name for the certificate collection. This name appears at the top of the page for this collection and can be configured to appear on the Management Portal menu under Certificates. It will also appear in other places within the Management Portal where you can reference certificate collections (e.g. expiration alerts and certain reports and dashboards). Because it can appear on the menu and in selection dropdowns, the name should be fairly short.
- 3. Enter a description for the collection. This description appears as a subtitle below the collection name on the page for this collection and can be more detailed than the collection name.
- 4. Select a setting in the *Ignore renewed certificate results by* dropdown. The *Ignore* dropdown applies to processing reports or expiration alerts and contains these options:

## None

Do not eliminate duplicate certificates when processing reports or expiration alerts based on this certificate collection.

## **Common Name**

Eliminate duplicate certificates based on the common name in the certificate when processing reports or expiration alerts. Certificates will be excluded from reports and expiration alerts if they share the same common name and enhanced key usage (EKU—e.g. Client Authentication). The certificate with the most recent issued date and the given common name and EKU will be included in the report or expiration alert.

## **Distinguished Name**

Eliminate duplicate certificates based on the distinguished name in the certificate when processing reports or expiration alerts. Certificates will be excluded from reports and expiration alerts if they share the same distinguished name and EKU. The certificate with the most recent issued date and the given distinguished name and EKU will be included in the report or expiration alert.

## **Principal Name**

Eliminate duplicate certificates based on the principal name in the certificate status data stored in the Keyfactor Command database for the certificate when processing reports or expiration alerts. The principal name is added to the certificate status data for the certificate during certificate synchronization if the certificate SAN contains a *user principal name* or *NT principal name*. Certificates will be excluded from reports and expiration alerts if they share the same principal name and EKU. The certificate with the most recent issued date and the given principal name and EKU will be included in the report or expiration alert.

## **Keyfactor Renewal**

Eliminate duplicate certificates based on certificates that have been renewed through Keyfactor Command.

**Note**: Regardless of the selection you make in the Ignore option, all certificates will appear in the search results grid. Duplicate certificates are not excluded on this page. When processing reports or expiration alerts based on this certificate collection, only certificates that share all the EKUs (e.g. Client Authentication and Server Authentication) as well as the same CN, DN or UPN will be eliminated as duplicates. If a certificate has more than one EKU and at least one EKU does not match an otherwise similar certificate with matching CN, DN or UPN, it will not be eliminated on reports or expiration alerts.

5. Check the Show on Dashboard box to include the results from this collection on the Collection dashboard (see <u>Dashboard</u>: Collections on page 13). You will not be able to change this setting once the collection is saved. If you need to change it, you would need to edit the collection and re-save it.

**Note**: The collections dashboard widget will only display the first 25 collections alphabetically. A brief warning message explaining this will be shown on the collections save dialog when the **Show on Dashboard** box is checked.

- 6. Check the **Show in Navigator** box to include the collection on the Management Portal menu (on the *Certificates* top-level menu dropdown).
- 7. Click **Save** to save the collection. The search results will display immediately. If you didn't select the **Show in Navigator** option, you can find the collection again on the Certificate Collection

Management page, accessed by navigating to Certificates > Collection Manager from the Management Portal.

Tip: If you Save a new certificate collection, or Save a change to an existing certificate collection, that change will be immediately reflected in the collection data used to display certificate collections on dashboards and reports. The data used by the dashboards and reports is stored in an intermediate table that is updated immediately. It will also continue to be updated periodically (approximately every 20 minutes by default as configured by the Dashboard Collection Caching Interval application setting) by the Keyfactor Command Service (see Application Settings: Console Tab on page 603).

## 2.1.3.3 Certificate Operations

Most common certificate operations (except enrollment) are available on the Certificate Search grid. The actions available on the grid header include: Edit (users with read-only permissions will see Display instead), Delete, Revoke, Edit All, Revoke All, Delete All (for collections only), and Get CSV. Secondary operations are shown on the context menu, accessed by right-clicking on a selected row on the Certificate Search grid. The context menu includes Edit (or Display), Delete, Delete Private Key, Revoke, Download, Add to Certificate Store, Remove from Certificate Store, Renew, and Identity Audit. There is also an operation to place a hold, or remove a hold, on a certificate, which is available from the Revoke operation through the Revocation Reason: Certificate Hold/Remove From Hold. When selecting multiple rows, only the operations Edit, Delete, Revoke and Delete Private Key (only if the private key is stored in the database) are enabled on the grid header and the context menu. For the edit commands, the only details that can be edited are the metadata fields.

Note: As of Keyfactor Command version 10, enrollment (PFX and CSR), renewal, and revocation requests all flow through Keyfactor Command workflow. This will result in no changes to the enrollment, renewal, and revocation user experience unless customizations have been added in workflow (see Workflow Definitions in the Keyfactor Command Reference Guide).

Full descriptions of the available certificate operations are below.

## Add to Certificate Store

Before adding a certificate to a certificate store in Keyfactor Command, you must approve an orchestrator to handle the store and create a record for the store in Keyfactor Command. See Orchestrator Management on page 497 and Certificate Store Operations on page 414.

Tip: The following permissions (see Security Roles and Claims in the Keyfactor Command Reference Guide) are required to use this feature:

Certificates > Collections > Read Certificates > Collections > Private Key > Read Certificate Stores > Read Certificate Stores > Schedule

Permissions for certificates and certificate stores can be set at either the global or certificate collection and certificate store container level. See Certificate Collection Permissions on page 628 and Container Permissions on page 630 for more information about global vs collection and container permissions.

Note: Certificates cannot be added to stores that require private keys from this interface unless the selected certificate contains a private key stored in the database. If the selected certificate does not contain a stored private key, stores that require a private key will not appear on the Select Certificate Store Locations dialog.

To add a certificate to a certificate store:

- 1. Highlight the row in the results grid and right-click.
- 2. Choose Add to a Certificate Store from the right-click menu.
- 3. When you select the Add to Certificate Store option the Select Certificate Store Locations dialog opens. When you select the certificate stores to which you want to deploy your certificate and click Include, the Add to Certificate Stores dialog appears BEHIND the Select Certificate Store Locations dialog, holding your selection and leaving the Select Certificate Store Locations dialog open for you to continue selecting locations. The final list of selections will only be accessible once you close the Select Certificate Store Locations dialog using the Include and Close button.

## Select Certificate Store Locations

The Select Certificate Store Locations dialog allows you to run queries against your certificate store list to select which store(s) to deploy a selected certificate to. Check the box next to each certificate store location to which you want to distribute the certificate.

Note: Only compatible certificate stores and only stores in containers to which you have permissions are shown on the grid.

Tip: You may change the search results by using the search fields at the top of the dialog. All of the Keyfactor Command grid search features are available to assist your search. See Using the Certificate Store Search Feature on page 411 for more information on the available search fields. The default search criteria is AgentAvailable is equal to True.

The actions on the Select Certificate Store Locations dialog are:

### Include

Click this to add the selected certificate store(s) to your certificate selection and leave the search dialog open for further searches.

## • Include and Close

Click this to close the search dialog and add the selected certificate store(s) to your certificate selection, which will then be displayed and ready for updates as per the instructions in *Add to Certificate Stores*.

#### Close

Click this to cancel the operation and return to the main page with no certificate stores selected.

Figure 30: Select Certificate Store Locations Dialog

## Add to Certificate Stores

The Add to Certificate Stores page appears once you select at least one certificate store to distribute your certificate to. It includes a grid section with a series of tabs that display a tab for each type of certificate store selected with a list of the selected stores under each tab. The header section of the dialog shows global options that apply to the add job as a whole:

### • Include Certificate Stores

You may return to the *Select Certificate Store Locations* dialog by clicking **Include Certificate Stores** above the grid. The current selections will be retained.

## · Schedule when to run the job for the certificate store

In the **Schedule** dropdown, select a time at which the job to add the certificate to the stores should run. The choices are *Immediate* or *Exactly Once* at a specified date and time. If you choose *Exactly Once*, enter the date and time for the job. A job scheduled for *Immediate* running will run within a few minutes of saving the operation. The default is *Immediate*.

## Include Private Key on Certificate Stores when the Private Key is optional

Check the **Include Private Key** box if you want to deliver the private key of the certificate to any selected certificate stores that do not require a private key (e.g. Java keystores). This option only appears for certificates that have a private key available for distribution.

Click **Remove** at the top of the grid to remove the selected certificate store from the page. The certificate will not be added to the store.

For each selected certificate store you can apply the following actions:

### Overwrite

Check **Overwrite** below the grid to overwrite any existing certificate in the same location and with the same name or alias for the selected certificate store type.

#### Alias

Add an **Alias** below the grid, if applicable, for the certificate store type. See the **Information Required by Certificate Store** section, below, for more information.

**Note**: The tab heading of the certificate location will display an alert if an alias is required for the location. If *Supports Custom Alias* is set to **Forbidden** on the certificate store type, the **Alias** field will not display unless *Overwrite* is checked on this page.

Figure 31: Add Certificate—Install into Certificate Locations

Figure 32: Alias Required Alert on Save

# **Information Required by Certificate Stores**

Each type of certificate store has different requirements for providing an alias or other additional information.

The certificate store type fields that are relevant to certificate store use are:

# Supports Entry Password

If your certificate store type has this enabled, you will have the option to enter a password for the certificate entry in the certificate store on the addition of an entry into the certificate store.

Figure 33: Certificate Store Type Configuration: Basic Tab

## Supports Custom Alias

A value of *Required* indicates that a custom alias will be required when a certificate is added to a certificate store. *Optional* indicates an alias can be associated with the entry if desired. If your certificate store type sets this to *Forbidden*, the *Alias* field will not display when adding a certificate to a certificate store unless *Overwrite* is checked on the add page. In this case, you're not associating an alias with the certificate you're adding to the store but rather specifying the alias of the certificate already in the store that you wish to replace (in function) with the new certificate you're adding.

The format of custom alias values varies depending on the certificate store type. In many cases, the alias is the thumbprint of the certificate. In some cases, it's the file name of the certificate file or a custom alias provided at the time the certificate was added to the certificate store. For instance:

 For an Amazon Web Services (AWS) store, the alias is the internal ID assigned by Amazon (the Amazon resource number or ARN). Provide the entire contents of the Alias/IP from this field when entering an alias for overwrite. For example:

arn:aws:acm:us-west-2:220531701668:certificate/88e5dcfb-a70b-4636-a8ab-e85e8ad88780

For F5 stores using the Keyfactor custom-built F5 Certificate Store Manager extension (see *Installing Custom-Built Extensions* in the *Keyfactor Orchestrators Installation and Configuration Guide*), the alias is the file name used to store the file in the device file system, minus the extension (e.g. use alias MyFile for a file named MyFile.crt). Aliases should be entered without spaces. Note that certificate names are case sensitive.

**Note**: Keyfactor Command will automatically strip out any spaces between the octets in thumbprints in the alias field, so it does not matter whether you enter the thumbprint with or without spaces.

**Tip:** When adding a certificate to a certificate store, you have the option to overwrite an existing certificate with the current certificate. If you choose this option, you will need to provide the alias of the certificate you wish to overwrite. Find the alias values by navigating to *Management Portal > Certificates > Certificate Search*. Select the certificate you wish to overwrite and double-click, or click **Edit**, from the grid header or right-click menu. Choose the **Locations** tab and double-click on the Location Type (this must have a number other than zero in the *Count column*) to open the details dialog. The *Alias* field holds the information that may be required for an overwrite.

## Private Key Handling

When adding a certificate to a certificate store, if you select a certificate that does not have an associated private key, certificate stores with this option set to *Required* will not appear as available stores to which the certificate can be added. If this option is set to *Forbidden* and the selected certificate has a private key, the private key will be ignored and only the public key will be delivered to the target.

Note: Private keys are always available in PFX Enrollment.

Figure 35: Certificate Store Type Configuration: Advanced Tab

## Entry Parameters

Not all certificate store types will have entry parameters. The ones shown in <u>Figure 36:</u> <u>Certificate Store Type Configuration: Entry Parameters Tab</u> are for the custom *Windows Certificate* type for the Keyfactor custom-built IIS Certificate Store Manager extension (see *Installing Custom-Built Extensions* in the *Keyfactor Orchestrators Installation and Configuration Guide*).

Figure 36: Certificate Store Type Configuration: Entry Parameters Tab

4. Click **Save** to submit the certificate store additions.

**Note**: When you save this job, a new management job will be added to the orchestrator jobs list. In addition a one-time inventory job will be added immediately following the management job to update Keyfactor Command with the changes to the certificate store. The one-time inventory job does not appear in the orchestrator jobs list in the Management Portal.

## **Delete**

Select one or more certificates in the results grid and then click **Delete** at the top of the grid or **Delete** in the right-click menu to remove the selected certificate(s) from the Keyfactor Command database. If the selected certificates have associated private keys stored in the database, these private keys are also removed. The certificates will be returned to the Keyfactor Command database on the next full synchronization if synchronization for the certificate source (certificate authority, SSL endpoint, etc.) is still configured. Certificate history and private keys do not return when certificates re-synchronize.

Whenever a certificate is deleted that is a part of a certificate renewal chain. The certificates on either end of the deleted cert(s) will have their certificate histories updated to show that either a certificate before or after the certificate was deleted in the renewal chain of that certificate.

**Tip**: The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Certificates > Collections > Read

Certificates > Collections > Delete

Permissions for certificates can be set at either the global or certificate collection level. See *Certificate Permissions* in the *Keyfactor Command Reference Guide* for more information about global vs collection permissions.

## **Delete All**

This option is available only in saved collections, not in standard certificate searches. Click the **Delete All** action button at the top of the collection grid. The button appears active only if no certificates are selected on the grid. A large deletion may take several minutes to complete. The certificates will be returned to the Keyfactor Command database on the next full synchronization if synchronization for the certificate source (certificate authority, SSL endpoint, etc.) is still configured.

**Tip**: The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Certificates > Collections > Read

Certificates > Collections > Delete

Permissions for certificates can be set at either the global or certificate collection level. See *Certificate Permissions* in the *Keyfactor Command Reference Guide* for more information about global vs collection permissions.

## **Delete Private Key**

Click the **Delete Private Key** in the right-click menu to remove the private key of the selected certificate(s) from the Keyfactor Command database. This option is only available if the private key is stored in the database.

**Tip**: The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Certificates > Collections > Read

Certificates > Collections > Delete

Permissions for certificates can be set at either the global or certificate collection level. See *Certificate Permissions* in the *Keyfactor Command Reference Guide* for more information about global vs collection permissions.

## Download

Click **Downland** in the right-click menu to download the selected certificate to the local computer with or without a private key. Only one certificate may be downloaded at a time.

**Tip**: The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Certificates > Collections > Read

Certificates > Collections > Delete

To download a certificate without a private key.

Certificates > Collections > Read

Certificates > Collections > Delete

Certificates > Collections > Private Key > Read

For users who will be downloading certificates with private keys.

Permissions for certificates can be set at either the global or certificate collection level. See *Certificate Permissions* in the *Keyfactor Command Reference Guide* for more information about global vs collection permissions.

**Note**: The Recover option that was found in previous versions of Keyfactor Command is now part of the Download option.

You will be able to download a certificate including its private key if one of the following is true:

- The certificate has been stored in the Keyfactor Command database with its private key.
- The certificate was issued using a template that had key archival enabled, issued from a Microsoft CA that has a valid Key Recovery Agent certificate, and that Key Recovery Agent certificate is configured on the Keyfactor Command server.

Important: In order to successfully download certificates and retrieve their associated private keys using Microsoft key recovery, the service account under which the Keyfactor Command application pool is running must be granted "Issue and Manage Certificates" permission to the CA database as per *Create Active Directory Groups to Control Access to Keyfactor Command Features* in the *Keyfactor Command Server Installation Guide*, or, if delegation is configured for the CA, the user executing the download must have these permissions.

In order to support key recovery within Keyfactor Command, you need to import at least one Key Recovery Agent certificate with a private key into the Keyfactor Command application pool user's personal certificate store on each Management Portal server. See Configuring Key Recovery for Keyfactor Command on page 789.

Tip: CA-level key recovery is supported for Microsoft CAs to allow recovery of private keys for certificates enrolled outside of Keyfactor Command. CA-level key archiving is not supported for enrollments done through Keyfactor Command. CA-level key recovery is not supported for EJBCA CAs. For enrollments done through Keyfactor Command for either Microsoft or EJBCA CAs, use Keyfactor Command private key retention (see Details Tab on page 388).

Note: Downloading of the private key is logged and reflected on the History tab of the certificate details (see History Tab on page 33).

To download a certificate that has the private key stored in the Keyfactor Command database:

- 1. Highlight the row in the results grid and right-click.
- 2. Choose Download from the right-click menu, or the action button on the Certificate Details dialog.

Figure 37: Certificate Operation: Download Certificate with Private Key

In the Download dialog, select the Include Private Key option to include the private key of the
certificate in the download. The Include Private Key option is supported for PEM, PFX and JKS
outputs.

**Note**: If you choose **Include Private Key**, *after* you click **Download** (step 7, below), a PFX/PEM/JKS Password dialog will pop-up with the one-time password and action buttons to **Copy Password** or **Close** the pop-up. Clicking **Copy Password** will copy the password to the clipboard. As a security measure, the dialogue will close after 2 minutes. To secure the downloaded file, you will need this password in order to access the PFX, PEM, or JKS file generated by the download. Click **Close** to close the PFX/PEM/JKS Password dialog once you have copied the password.

Figure 38: Certificate Operation: Password for Certificate with Private Key

**Important**: The randomly generated password cannot be regenerated, so it must be copied prior to closing the dialog.

- 4. Select **Include Chain** to include the certificate chain (root and intermediate certificates) in the download, if required.
- 5. If you selected Include Chain, select a **Chain Order** for the certificates in the resulting output file—either **End Entity First** (at the beginning of the file) or **Root First**. Chain Order is supported for PEM and P7B outputs. PFX output always includes the end entity certificate first.
- 6. Chose an encoding format (options include: DER, P7B, PEM, ZIP PEM, JKS, PFX).

**Note**: Selecting the *Include Private Key* and *Include Chain* options changes which formats are available.

7. Click **Download** to begin the download.

To download a certificate that does not have the private key stored in the Keyfactor Command database:

- 1. Highlight the row in the results grid and right-click.
- 2. Choose **Download** from the right-click menu.

Figure 39: Certificate Operation: Download Certificate without Private Key

- 3. Chose **Include Chain** to include the certificate chain (root and intermediate certificates) in the download, if required. Include Chain is supported for PEM and P7B outputs.
- 4. If you selected Include Chain, select a **Chain Order** for the certificates in the resulting output file—either *End Entity First* (at the beginning of the file) or *Root First*. Chain Order is supported for PEM and P7B outputs.
- 5. Chose an encoding format.
  - Note: Selecting the *Include Chain* option changes which formats are available.
- 6. Click **Download** to begin the download.

# Edit (Display)

Select one certificate in the results grid and then click **Edit** at the top of the grid, or **Edit** in the right-click menu, or double-click the row, to pop up the certificate details dialog box in which you can view

details of the certificate data and edit metadata fields for the certificate. Users without *Edit Metadata* permissions to certificates will see a **Display** option instead of an **Edit** option.

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Certificates > Collections > Read Certificates > Collections > Metadata Modify Certificate Stores > Read

The *Metadata Modify* permission is only needed for users who will be modifying the values of metadata fields for certificates. Users with *Read* permissions may view the exiting metadata values.

The *Read* permission for *Certificate Store Management* is only needed for users who will be viewing values on the Locations tab.

Permissions for certificates and certificate stores can be set at either the global or certificate collection and certificate store container level. You can use a mixture with, for example, global certificate permissions and container-level certificate store permissions. See *Certificate Permissions* and *Container Permissions* in the *Keyfactor Command Reference Guide* for more information about global vs collection and container permissions.

**Note**: When you open a certificate for editing, only the custom Keyfactor Command metadata fields are editable.

Note, the certificate details dialog also includes buttons for the **download**, **revoke**, and **renew** (if applicable) operations for users with appropriate permissions. You cannot change any of the certificate attributes from Certificate Authority (shown on the Content tab) or any of the certificate status, validation, locations, or history data tracked by Keyfactor Command (shown on the Status, Validation, Locations and History tabs).

See Certificate Details on page 20 for more detailed information about the certificate details dialog.

If you select multiple certificates to edit at once, only the metadata fields dialog will appear. See **Edit All**.

## **Edit All**

Click **Edit All** at the top of the grid to open the metadata fields for all of the certificates in the query for editing. The button appears active only if no certificates are selected on the grid. All defined metadata fields—including those marked hidden—appear on the Edit All dialog. Each field includes an alert button that identifies whether the certificates in the query have all of same () or different () values for each metadata field. Click the alert button for an explanation of the impact the **Overwrite** settings for this field will have on the certificates.

See Metadata Tab on page 21 for more detailed information about the certificate details metadata.

Click **Allow Modifying** to enable the field for editing. Editing a field and selecting **Overwrite** will change the value for all certificates. Editing this field and not selecting **Overwrite** will only change the value for certificates that do not already have a value defined for this field.

**Tip**: The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Certificates > Collections > Read Certificates > Collections > Metadata Modify

Permissions for certificates can be set at either the global or certificate collection level. See *Certificate Permissions* in the *Keyfactor Command Reference Guide* for more information about global vs collection permissions.

Figure 40: Certificate Operation: Edit All

Figure 41: Certificate Operation: Edit All Alerts

Tip: The following setting will need to be configured to run 1+ million certificates in an Edit All request. In the IIS Management console, browse to Default Web Site > Advanced Settings > Limits > Connection timeout. Set this to a value higher than the default of 120, for example 360.

### **Get CSV**

Click **Get CSV** from the top of the grid to download all the certificates in the results grid to a comma-delimited CSV file. The button appears active only if no certificates are selected on the grid.

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Certificates > Collections > Read

Permissions for certificates can be set at either the global or certificate collection level. See *Certificate Permissions* in the *Keyfactor Command Reference Guide* for more information about global vs collection permissions.

The CSV file will contain the following information for each exported certificate:

- Issued DN
- Import Date
- · Effective Date
- · Expiration Date
- Issued CN
- · Certificate Authority Name
- Template Display Name
- Principal
- Requester
- Key Type
- · Key Size
- · Certificate State
- Thumbprint
- Serial Number

A confirmation dialog will pop up providing an approximate file size of the file that will be generated. A CSV file generated from a very large result set may take a long time to download or may be unwieldy to edit.

Figure 43: Certificate Operation: CSV Download

# **Identity Audit**

Click **Identity Audit**in the right-click menu to view the certificate level permissions (read, edit metadata, download with private key, revoke, and delete) granted to all user roles defined in Keyfactor Command (see <u>Security Roles and Claims on page 623</u>) for the selected certificate.

**Tip**: The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature: Auditing > Read

## Certificates > Collections > Read Security > Read

Permissions for certificates can be set at either the global or certificate collection level. See *Certificate Permissions* in the *Keyfactor Command Reference Guide* for more information about global vs collection permissions.

Figure 44: Certificate Operation: Identity Audit

#### Remove from Certificate Store

Click **Remove from Certificate Store** in the right-click menu to remove the selected certificate from a certificate store or stores. Two dialog boxes will pop up as per <a href="Add to Certificate Store">Add to Certificate Store</a> on <a href="page 46">page 46</a> allowing you to select the certificate store(s) from which you wish to remove the certificate. In the first dialog, select the certificate store from which you want to remove the certificate and click the **Include and Close** button and then click **Save** in the second dialog. Only certificate stores that contain the certificate and to which the user has permissions will be shown.

**Tip**: The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Certificates > Collections > Read Certificates Stores > Read Certificates Stores > Schedule

Permissions for certificates and certificate stores can be set at either the global or certificate collection and certificate store container level. You can use a mixture with, for example, global certificate permissions and container-level certificate store permissions. See *Certificate Permissions* and *Container Permissions* in the *Keyfactor Command Reference Guide* for more information about global vs collection and container permissions.

Tip: The small Remove button at the top of the grid applies to managing the list in the grid only and will remove certificate stores from the selection of stores in the grid. Highlight a row and click remove to remove it from the list.

Figure 45: Certificate Operation: Select Stores for Remove from Certificate Store

Figure 46:Remove from Cert Store Save Page

**Note:** When you save this job, a new management job will be added to the orchestrator jobs list. In addition a one-time inventory job will be added immediately following the management job to update Keyfactor Command with the changes to the certificate store. The one-time inventory job does not appear in the orchestrator jobs list in the Management Portal.

## Renew

Click Renew in the right-click menu to renew or re-issue the selected certificate.

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Certificates > Collections > Read

Certificates > Enrollment > Pfx

Certificates Stores > Read

Certificates Stores > Schedule

Permissions for certificates and certificate stores can be set at either the global or certificate collection and certificate store container level. You can use a mixture with, for example, global certificate permissions and container-level certificate store permissions. See

Certificate Permissions and Container Permissions in the Keyfactor Command Reference Guide for more information about global vs collection and container permissions.

The renewal dialog includes the options:

- One-click renewal (the Continue option), which supports renewal with no further user interaction. If you wish to use One-Click Renewal for certificates, the Allow One-Click Renewals option must be enabled in both the templates and CAs to which you want One-Click Renewal to apply (see Certificate Template Operations and Certificate Authority Operations in the Keyfactor Command Reference Guide).
- Seeded PFX enrollment (the **Configure** option), to be redirected to the PFX Enrollment page with the information for the certificate pre-populated in the enrollment fields. The **Continue** option is only available if either one of the following is true:
  - The certificate is located *together with its private key* in one or more managed certificate store(s).
  - The certificate was enrolled with a template that has been configured in Keyfactor Command to allow private keys to be encrypted and stored in the Keyfactor Command database (see Certificate Template Operations on page 382).

Figure 47: Certificate Operation: Renew/Reissue with the Continue Option

**Note:** The **Continue** option is only supported if the user performing the renewal has permissions to enroll using the template and CA associated with the original certificate.

From the seeded PFX Enrollment page, you can change the CA or template for enrollment, change the subject information or metadata for the certificate, set or remove SANs, or change the certificate store(s) to which the renewed certificate will be distributed. To change the certificate store(s) for distribution, on the PFX Enrollment page, scroll down to the Certificate Delivery Format section and click the **Include Certificate Stores** button. This will open the *Select Certificate Store Locations* dialog. For more information, see <a href="Add to Certificate Store">Add to Certificate Store</a> on page 46 and <a href="PFX Enrollment on page 146">PFX Enrollment on page 146</a>.

Certificates issued by Microsoft CAs will be renewed (meaning the certificate will be issued with a different private key) regardless of how recently they were issued. Certificates issued by other certificate authorities will be renewed (typically retaining the same private key but with a new expiration date) if they are within the renewal window specified by the certificate template and re-issued (retaining the same expiration date) if they are not yet within the renewal window.

**Note**: Certificate renewal is only supported when attempting to renew the most recently issued certificate in a renewal chain. In other words, if a certificate has been renewed three times resulting in certificates 1, 2 and 3 (1 being the initially issued certificate and 3 being the most recently issued certificate), you can renew certificate 3 but not certificate 2 or 1.

**Note**: As of Keyfactor Command version 10, enrollment (PFX and CSR), renewal, and revocation requests all flow through Keyfactor Command workflow. This will result in no changes to the enrollment, renewal, and revocation user experience unless customizations have been added in workflow (see *Workflow Definitions* in the *Keyfactor Command Reference Guide*).

**Note**: When you save this job, a new management job will be added to the orchestrator jobs list. In addition a one-time inventory job will be added immediately following the management job to update Keyfactor Command with the changes to the certificate store. The one-time inventory job does not appear in the orchestrator jobs list in the Management Portal.

#### Revoke

Select one or more certificates in the results grid and then click **Revoke** to revoke the selected certificate(s). When you select revoke, a dialog box pops up prompting for the effective revocation date, the reason for the revocation (for which there are dropdown choices), and comments (required). Upon completion of the revocation, the CRL for the CA in question is immediately republished to reflect the revocation. Unless you choose the revocation reason of *Certificate Hold*, there is no way to undo a revoke so care should be taken with this operation.

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Certificates > Collections > Read Certificates > Collections > Revoke

Permissions for certificates can be set at either the global or certificate collection level. See *Certificate Permissions* in the *Keyfactor Command Reference Guide* for more information about global vs collection permissions.

Important: In order to successfully revoke certificates, the service account under which the Keyfactor Command application pool is running must be granted "Issue and Manage Certificates" and "Manage CA" permissions to the CA database as per *Create Active Directory Groups to Control Access to Keyfactor Command Features* in the *Keyfactor Command Server Installation Guide*, or, if delegation is configured for the CA, the user executing the revoke must have the "Issue and Manage Certificates" permissions while the application pool service account has the "Manage CA" permissions. If you are using explicit credentials to authenticate your CA (see <a href="Adding or Modifying a CA Record on page 355">Adding or Modifying a CA Record on page 355</a>), it is the user specified on the CA configuration in Keyfactor Command who must have both these permissions on the CA.

**Note**: As of Keyfactor Command version 10, enrollment (PFX and CSR), renewal, and revocation requests all flow through Keyfactor Command workflow. This will result in no changes to the enrollment, renewal, and revocation user experience unless customizations have been added in workflow (see *Workflow Definitions* in the *Keyfactor Command Reference Guide*).

Figure 48: Certificate Operation: Revoke

# Revoke: Certificate Hold / Remove from Hold

If you would like to suspend one or more certificates without permanently revoking them, select one or more certificates in the results grid and then click **Revoke** at the top of the grid or **Revoke** on the right-click menu. Select **Certificate Hold** as the revocation reason. You will be required to add a comment in the *Comments* field to **Save** the record change.

When you **Revoke** a certificate using the revocation reason of **Certificate Hold**, the certificate is in the revoked state, with the revocation reason of **Certificate Hold**. You will only be able to see the certificate on a certificate search with *Include Revoked* checked. To return the certificate to the Active state, **Revoke** it again with the reason **Remove from Hold**. You will be required to add a comment in the *Comments* field to **Save** the record change.

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Certificates > Collections > Read

Certificates > Collections > Revoke

Permissions for certificates can be set at either the global or certificate collection level. See *Certificate Permissions* in the *Keyfactor Command Reference Guide* for more information about global vs collection permissions.

**Note**: As of Keyfactor Command version 10, enrollment (PFX and CSR), renewal, and revocation requests all flow through Keyfactor Command workflow. This will result in no changes to the enrollment, renewal, and revocation user experience unless customizations have been added in workflow (see *Workflow Definitions* in the *Keyfactor Command Reference Guide*).

## **Revoke All**

If you would like to revoke ALL the certificates in the current query results set, click **Revoke All** at the top of the grid. The button appears active only if no certificates are selected on the grid.

When you select revoke all, a dialog box pops up prompting for the effective revocation date, the reason for the revocation (for which there are dropdown choices), comments (required), and confirmation of the number of certificates being revoked. In the confirmation field, you must type the suggested message, which includes the number of certificates being revoked, exactly as indicated, including case (e.g. "REVOKE 52" not "revoke 52").

If any certificates fail revocation, their certificate IDs will be listed in a dialog at the completion of the revocations.

Upon completion of the revocations, the CRL(s) for the CA(s) in question is immediately republished to reflect the revocations. Unless you choose the revocation reason of *Certificate Hold*, there is no way to undo a revoke so care should be taken with this operation.

A maximum of 1000 certificates can be revoked at once with this option. If the query contains more certificates than this, a warning dialog will appear and you will not be allowed to continue with the revocation.

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Certificates > Collections > Read Certificates > Collections > Revoke

Permissions for certificates can be set at either the global or certificate collection level. See *Certificate Permissions* in the *Keyfactor Command Reference Guide* for more information about global vs collection permissions.

**Note:** As of Keyfactor Command version 10, enrollment (PFX and CSR), renewal, and revocation requests all flow through Keyfactor Command workflow. This will result in no changes to the enrollment, renewal, and revocation user experience unless customizations have been added in workflow (see *Workflow Definitions* in the *Keyfactor Command Reference Guide*).

**Note**: The Revoke All option can be removed from display on the certificate search pages using the *Revoke All Enabled* application setting (see <u>Application Settings: Console Tab on page 603</u>).

Figure 49: Certificate Operation: Revoke All

#### 2.1.3.4 Add Certificate

The add certificate tool supports importing certificates with the following formats and extensions:

- PEM: .cer or.crt
   If your PEM file has an extension of .pem, rename it to .cer or .crt before using the Add Certificate tool.
- PKCS#12: .pfx or .p12
- PKCS#7: .p7b

This tool has several purposes, including:

- It can be used to import certificates generated outside the enterprise PKI environment—such as
  those purchased from a commercial certificate vendor or generated by a non-Microsoft or nonEJBCA CA.
- It can be used to import certificates that would not be automatically imported during a synchronization of configured Microsoft or EJBCA CAs such as root CA certificates or certificates with unusual key types (e.g. Dilithium) that aren't supported by synchronization.
- It can be used to import certificates acquired using CSRs generated by Keyfactor Command and issued by a CA not managed using Keyfactor Command to allow for ongoing management with Keyfactor Command.
- It can be used to push a certificate with the associated private key out to a certificate store when you have the appropriate .pfx or .p12 file available.
- It can be used as a quick shortcut to push a certificate without a private key out to a certificate store when you have the certificate file in hand and don't want to search for the certificate in Keyfactor Command in order to push it out to the certificate store.

Before you can add a certificate to a certificate store with this option, you must first add the certificate store in Keyfactor Command (see <u>Certificate Stores on page 409</u>) and install, start, and approve the orchestrator (see <u>Orchestrator Management on page 497</u> and the *Keyfactor Orchestrators Installation and Configuration Guide*.

If you import a certificate that has either already been imported via a synchronization task or has been manually imported previously, the certificate will not be re-imported. You will receive a notification message, when you save it, if the certificate already exists in the Keyfactor Command database. Any metadata currently stored in the database for that certificate will be displayed in the metadata fields on the page (for .cer and .crt format certificates), and any changes you make to the metadata on this page will overwrite the existing metadata for the certificate when you complete the import (for all certificate formats).

To use the add certificate tool

- 1. In the Management Portal, browse to Certificates > Add Certificate.
- 2. In the Add Certificate section of the page, click the Upload button to open a browse window.
- 3. In the browse window, browse to select the certificate you wish to import.
- 4. For a .pfx or .p12 file, when prompted enter the password for the file and Save. This will open the Add Certificate page, which will allow you to change/add metadata and choose certificate locations to deploy the certificate to. Set PFX Password allows you to reenter the password once you have uploaded the certificate.

Figure 50: Add Certificate Password for PFX/p12

5. In the Certificate/PFX Details section of the page, review the certificate information.

Figure 51: Add Certificate Information

6. In the *Metadata* section of the page, populate the metadata fields as appropriate for the certificate. Metadata fields that have been designated as required on a system-wide or template-level basis will be marked with \*Required.

Figure 52: Add Certificate Metadata

7. In the Install into Certificate Locations section of the page, select each certificate store location to which you want to distribute the certificate, if desired. To do this, click the Include Certificate Stores button. This will cause the Select Certificate Store Locations dialog to appear. Make your certificate store selections in this dialog as described in Select Certificate Store Locations, below, and click Include and Close. You will then see some additional fields on the page. Populate these as per Add to Certificate Stores and Information Required for Certificate Stores, below.

## **Select Certificate Store Locations**

The Select Certificate Store Locations dialog allows you to run queries against your certificate store list to select which store(s) to deploy a selected certificate to. Check the box next to each certificate store location to which you want to distribute the certificate.

Note: Only compatible certificate stores and only stores in containers to which you have permissions are shown on the grid.

Tip: You may change the search results by using the search fields at the top of the dialog. All of the Keyfactor Command grid search features are available to assist your search. See Using the Certificate Store Search Feature on page 411 for more information on the available search fields. The default search criteria is AgentAvailable is equal to True.

The actions on the Select Certificate Store Locations dialog are:

#### Include

Click this to add the selected certificate store(s) to your certificate selection and leave the search dialog open for further searches.

#### Include and Close

Click this to close the search dialog and add the selected certificate store(s) to your certificate selection, which will then be displayed and ready for updates as per the instructions in Add to Certificate Stores.

## Close

Click this to cancel the operation and return to the main page with no certificate stores selected.

Figure 53: Select Certificate Store Locations Dialog

## **Add to Certificate Stores**

The Add to Certificate Stores page appears once you select at least one certificate store to distribute your certificate to. It includes a grid section with a series of tabs that display a tab for each type of certificate store selected with a list of the selected stores under each tab. The header section of the dialog shows global options that apply to the add job as a whole:

#### Include Certificate Stores

You may return to the *Select Certificate Store Locations* dialog by clicking **Include Certificate Stores** above the grid. The current selections will be retained.

#### · Schedule when to run the job for the certificate store

In the **Schedule** dropdown, select a time at which the job to add the certificate to the stores should run. The choices are *Immediate* or *Exactly Once* at a specified date and time. If you choose *Exactly Once*, enter the date and time for the job. A job scheduled for *Immediate* running will run within a few minutes of saving the operation. The default is *Immediate*.

Click **Remove** at the top of the grid to remove the selected certificate store from the page. The certificate will not be added to the store.

For each selected certificate store you can apply the following actions:

#### Overwrite

Check **Overwrite** below the grid to overwrite any existing certificate in the same location and with the same name or alias for the selected certificate store type.

#### Alias

Add an **Alias** below the grid, if applicable, for the certificate store type. See the **Information Required by Certificate Store** section, below, for more information.

**Note**: The tab heading of the certificate location will display an alert if an alias is required for the location. If *Supports Custom Alias* is set to **Forbidden** on the certificate store type, the **Alias** field will not display unless *Overwrite* is checked on this page

Figure 54: Add Certificate—Install into Certificate Locations

Figure 55: Alias Required Alert on Save

# Information Required by Certificate Stores

Each type of certificate store has different requirements for providing an alias or other additional information.

The certificate store type fields that are relevant to certificate store use are:

### Supports Entry Password

If your certificate store type has this enabled, you will have the option to enter a password for the certificate entry in the certificate store on the addition of an entry into the certificate store.

Figure 56: Certificate Store Type Configuration: Basic Tab

## Supports Custom Alias

A value of *Required* indicates that a custom alias will be required when a certificate is added to a certificate store. *Optional* indicates an alias can be associated with the entry if desired. If your certificate store type sets this to *Forbidden*, the *Alias* field will not display when adding a certificate to a certificate store unless *Overwrite* is checked on the add page. In this case, you're not associating an alias with the certificate you're adding to the

store but rather specifying the alias of the certificate already in the store that you wish to replace (in function) with the new certificate you're adding.

The format of custom alias values varies depending on the certificate store type. In many cases, the alias is the thumbprint of the certificate. In some cases, it's the file name of the certificate file or a custom alias provided at the time the certificate was added to the certificate store. For instance:

 For an Amazon Web Services (AWS) store, the alias is the internal ID assigned by Amazon (the Amazon resource number or ARN). Provide the entire contents of the Alias/IP from this field when entering an alias for overwrite. For example:

arn:aws:acm:us-west-2:220531701668:certificate/88e5dcfb-a70b-4636-a8ab-e85e8ad88780

o For F5 stores using the Keyfactor custom-built F5 Certificate Store Manager extension (see *Installing Custom-Built Extensions* in the *Keyfactor Orchestrators Installation and Configuration Guide*), the alias is the file name used to store the file in the device file system, minus the extension (e.g. use alias MyFile for a file named MyFile.crt). Aliases should be entered without spaces. Note that certificate names are case sensitive.

**Note**: Keyfactor Command will automatically strip out any spaces between the octets in thumbprints in the alias field, so it does not matter whether you enter the thumbprint with or without spaces.

**Tip:** When adding a certificate to a certificate store, you have the option to overwrite an existing certificate with the current certificate. If you choose this option, you will need to provide the alias of the certificate you wish to overwrite. Find the alias values by navigating to *Management Portal > Certificates > Certificate Search*. Select the certificate you wish to overwrite and double-click, or click **Edit**, from the grid header or right-click menu. Choose the **Locations** tab and double-click on the Location Type (this must have a number other than zero in the *Count* column) to open the details dialog. The *Alias* field holds the information that may be required for an overwrite.

## • Private Key Handling

When adding a certificate to a certificate store, if you select a certificate that does not have an associated private key, certificate stores with this option set to *Required* will not appear as available stores to which the certificate can be added. If this option is set to *Forbidden* and the selected certificate has a private key, the private key will be ignored and only the public key will be delivered to the target.

Note: Private keys are always available in PFX Enrollment.

Figure 58: Certificate Store Type Configuration: Advanced Tab

## Entry Parameters

Not all certificate store types will have entry parameters. The ones shown in <u>Figure 59:</u> <u>Certificate Store Type Configuration: Entry Parameters Tab</u> are for the custom *Windows Certificate* type for the Keyfactor custom-built IIS Certificate Store Manager extension (see *Installing Custom-Built Extensions* in the *Keyfactor Orchestrators Installation and Configuration Guide*).

Figure 59: Certificate Store Type Configuration: Entry Parameters Tab

8. Click Save to import the certificate to Keyfactor Command

Note: When you import a certificate containing a private key (a .pfx or .p12 file), the private key for that certificate is stored in the Keyfactor Command database. Users with limited permissions to the Add Certificate function may have permissions to upload certificates but not store private keys. If a user with this permission model uploads a certificate containing a private key, the certificate itself will be imported (if it does not already exist in the database), but the private key will not be stored. The user will receive a message indicating this. For more information about setting permissions for importing certificates, see Security Roles and Claims on page 623.

Tip: Click the help icon (2) next to the page title to open the embedded web copy of the Keyfactor Command Documentation Suite to this section.

You can also find the help icon at the top of the page next to the Log Out button. From here you can choose to open either the Keyfactor Command Documentation Suite at the home page or the Keyfactor API Endpoint Utility.

## 2.1.3.5 Certificate Collection Manager

The Certificate Collection Manager is used to:

- · View a list of certificate collections.
- Change whether or not the collections show in Navigator (the top menu, where they appear under Certificates).
- View whether or not the collections show in the dashboard widget (see <u>Dashboard: Collections</u> on page 13).
- · Delete a certificate collection.
- Search for specific certificate collections from the list (see <u>Using the Collection Manager</u> Search Feature on page 89).
- · View all the certificates in a collection.

Highlight the collection from the Certificate Collection Manager grid and click the **View** action button. This will open a new window with the name of the collection in a certificate search grid (see Viewing an Existing Certificate Collection on page 87).

**Tip:** An automated timer service runs against these collections (except *My Certificates*) to monitor certificates entering and leaving the collections so they can be used to trigger a custom workflow to manage your PKI health (see Workflow Definitions on page 230).

To open the Certificate Collection Management grid, browse to *Certificates > Collection Manager* in the Management Portal. The Certificate Collection Management page includes the following collection action buttons from the grid header:

- Set Show in Navigator on the collection to determine whether or not the collection appears in Navigator (the top menu under Certificates). To change this setting, highlight the row in the collection management grid and click Show in Navigator at the top of the grid, or right-click the collection in the grid and choose Show in Navigator from the right-click menu. This will toggle the Yes/No in the Show in Navigator grid column.
- To delete a collection, highlight the row (or rows) in the collection management grid and click
   Delete at the top of the grid or right-click the collection in the grid and choose Delete from the right-click menu.
- Highlight a row in the collection management grid and click View at the top of the grid, or rightclick the collection in the grid and choose View from the right-click menu to be taken to the list of certificates in that collection. Choosing this option will open the certificate search page in a new window filtered with the specific collection.

Figure 60: Certificate Collection Manager

# **Keyfactor Command Auto-Created Collections**

Several collections are created automatically when Keyfactor Command is installed.

· Certificates Expiring in 7 Days

This collection uses the special %TODAY% value in place of the current date to create a collection that can be used on any day to find the certificates that will expire within the next week. Only active certificates are included in this collection. The query for this collection is:

ExpirationDate -ge "%TODAY%" AND ExpirationDate -le "%TODAY+7%" AND CertState -eq "1"

· Certificates with Weak Encryption

This collection uses a variety of key type, key size, and signing algorithm queries to produce a collection that returns active certificates that have weak encryption. The query for this collection is:

((SigningAlgorithm -contains "SHA 1" OR SigningAlgorithm -contains "SHA1" OR SigningAlgorithm -contains "SHA-1") OR (SigningAlgorithm -contains "MD") OR (KeyType -eq 3 AND KeySize -lt 224) OR (KeyType -eq 1 AND KeySize -lt 2048)) AND CertState -eq "1"

My Certificates

This collection uses the special %ME% value in place of a specific user name to create a collection that any user can use to find the certificates on which they were the requester. The query for this collection is:

NetBIOSRequester -eq "%ME%"

**Note**: Certificate collections saved using the %ME% value are *not* supported for use in reports or on the dashboard.

· Revoked Certificates

This collection returns revoked certificates by querying for certificates that have a non-null revocation date. The *Include Revoked* box is automatically checked for this collection when run. The query for this collection is:

Self-Signed Certificates

This collection returns all certificates that are self-signed. In environments with no certificates imported from external sources (e.g. SSL scanning), this would typically just be CA certificates. The guery for this collection is:

SelfSigned -eq true

Important: The special query options of %TODAY%, %ME%, and %ME-AN% are only supported in uppercase. Lowercase equivalents (e.g. %me%) cannot be substituted.

Important: All automatically created collections are included on the menu by default, and all are included in the Certificate Collections Management grid by default. They are created for fresh installations of Keyfactor Command only, not upgrades, so as not to overwrite any userdefined collection for existing installations.

Tip: Click the help icon (3) next to the page title to open the embedded web copy of the Keyfactor Command Documentation Suite to this section.

You can also find the help icon at the top of the page next to the Log Out button. From here you can choose to open either the Keyfactor Command Documentation Suite at the home page or the Keyfactor API Endpoint Utility.

#### Viewing an Existing Certificate Collection

To view an existing certificate collection, either browse to the Certificates dropdown on the Management Portal menu and select the desired collection from the dropdown (if the collection has Show in Navigator set as Yes), or browse to Certificates > Collection Manager from the Management Portal and then select View, or double-click the row, from the Certificate Collection Management grid. When you select the collection for viewing, the search will begin immediately and the certificate search grid will open with the results from the collection. For information on using the certificate search grid, see Certificate Search Page on page 35.

Figure 61: View Collection

When viewing an existing collection, you can further refine the collection query by including additional selection criteria in the query field, but these are used in addition to the base query. You are not allowed to clear the base query for the collection, which is displayed above the advanced query field. For example, for the collection shown in <a href="Figure 62">Figure 62</a>: Collection with Query Modification, if the user added this in the query field:

CN -notcontains "keyother"

The query would return all the certificates issued in the last 30 days with the string appsrvr in the CN using a template referencing web but without the string keyother in the CN—in other words, the web server certificates for application servers issued in the last 30 days for the keyexample.com domain but not the web server certificates for application servers issued in the last 30 days for the keyother.com domain.

Figure 62: Collection with Query Modification

Available operations on a certificate collection include; **Save**, **Save** As, **Delete Collection** or view **Permissions** on the certificate collection.

Click **Save** to edit the existing collection. You may change the following about the collection from this option:

- The collection Name.
- The collection Description.
- The collection query Content.
- The Ignore Renewed Cert Results by setting.
- The Show on Dashboard setting.
- The Show on Navigator setting.

For more information on these, see Saving Search Criteria as a Collection on page 43.

**Note**: Certificate collections that are configured for *Certificate Entered Collection* or *Certificate Left Collection* workflows (see Workflow Definition Operations in the *Keyfactor Command Reference Guide*) cannot be edited. This is done to prevent triggering a large number of entered/left workflows.

Click **Save As** to create a new collection based on the existing collection. You can then edit the search criteria for the new collection without affecting the existing collection. Click **Delete Collec-**

tion to delete the certificate collection. Click **Permissions** to view collection level permission for the collection (see Certificate Collection Permissions on page 628).

**Tip:** If you **Save** a new certificate collection, or **Save** a change to an existing certificate collection, that change will be immediately reflected in the collection data used to display certificate collections on dashboards and reports. The data used by the dashboards and reports is stored in an intermediate table that is updated immediately. It will also continue to be updated periodically (approximately every 20 minutes by default as configured by the *Dashboard Collection Caching Interval* application setting) by the Keyfactor Command Service (see <u>Application Settings: Console Tab on page 603</u>).

## **Using the Collection Manager Search Feature**

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an *is null* or *is not null* comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

Each query consists of three parts:

# **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

#### Favorite

Whether the certificate collection has been marked as a favorite collection, meaning it will appear on the Navigator—on the Certificates top-level menu dropdown—true/false.

#### Query

Complete or partial matches with the string that makes up the search criteria for the certificate collection. For example:

(IssuedDate -ge \"%TODAY-7%\" AND
TemplateShortName -ne NULL) OR
(IssuedDate -ge \"%TODAY-7%\" AND
IssuerDN -contains \"keyexample\")

#### Name

Complete or partial matches with the name of the certificate collection.

## **Comparison Operator**

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the

equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Contains (-contains)
- Does not contain (-notcontains)
- Most date and integer fields support:
- Is equal to (-eq)
- Is not equal to (-ne)
- Is less than (-It)
- Is less than or equal to (-le)

Is greater than (-gt)

Starts with (-startswith)

Ends with (-endswith)

 Is null (-eq NULL) • Is not null (-ne NULL)

- Is greater than or equal to (-ge)
- Is null (-eq NULL)
- Is not null (-ne NULL)
- Most Boolean (true/false) fields support:
- Is equal to (-eq)
- Is not equal to (-ne)

- Is null (-eq NULL)
- Is not null (-ne NULL)

## Comparison Value

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

- Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.
- Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

## **Advanced Searches**

On any search page you can click Advanced to the right of the Search button to display the advanced search options. Click Simple to close the advanced search options again.

#### **Multiple Criteria**

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click Insert to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added

one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

# 2.1.4 Reports

Keyfactor Command uses the Logi Analytics Platform to provide a number of built-in reports based on certificate data in the Keyfactor Command database. These reports are available for viewing through the Management Portal, if you configured that option during the installation and configuration process (see *Install the Main Keyfactor Command Components on the Keyfactor Command Server(s): Dashboard and Reports Tab* in the *Keyfactor Command Server Installation Guide*). The reports can also be configured to save to a network path or deliver via email periodically, if desired.

As of Keyfactor Command version 10, Logi has been upgraded to v14 SP2 and a new Logi license is included in the application.

**Note:** Any CAs that have not been configured for synchronization will not appear as an option for reports which require selecting a CA.

Tip: If you **Save** a new certificate collection, or **Save** a change to an existing certificate collection, that change will be immediately reflected in the collection data used to display certificate collections on dashboards and reports. The data used by the dashboards and reports is stored in an intermediate table that is updated immediately. It will also continue to be updated periodically (approximately every 20 minutes by default as configured by the *Dashboard Collection Caching Interval* application setting) by the Keyfactor Command Service (see <u>Application Settings: Console Tab on page 603</u>).

Once a report has been generated, you may be able to export it to either PDF, Excel, or CSV. The export file types available for each standard report are shown in <u>Table 3: Chart of Available Exports</u> per Standard Report.

Table 3: Chart of Available Exports per Standard Report

PDF and Excel	Excel and CSV	PDF, Excel and CSV
Certificate Count by Template	Certificates Found at TLS/SSL Endpoints	Certificate Count Grouped by Single Metadata Fields
Certificate Count by User per Template	Certificates in Collection	
Certificate by Key Strength	Expiration Report by Days	
Certificates by Revoker	Full Certificate Extract	
Certificates by Type and Java Keystores	Revoked Certificates in Certificate Stores	
Certificate Issuance Trends with Metadata	SSH Keys with Root Logon Access	
Expiration Report	SSH Trusted Public Keys with No Known Private Key	
Issued Certificates Per Certificate Authority	SSH Key Usage Report	
Monthly Executive Report		
PKI Status for Collection		
Statistical Report		
SSH Keys by Age		

# **Report Drill-down**

Most reports now have drill-down capability. Clicking on a chart or graph segment in a report will open the corresponding query grid in a new browser window or tab populated with the query as defined by the selected graph segment. For example, for the *Certificates by Key Strength* report, clicking on a bar or pie will take you to the Certificate Search page pre-populated with the query that corresponds to that bar or pie.

#### Certificates by Key Strength

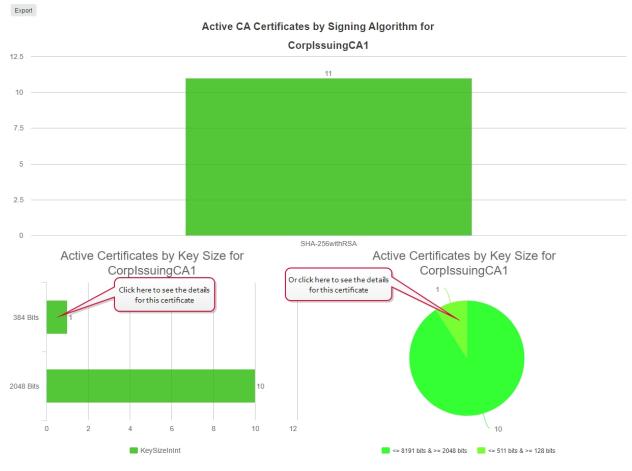

Figure 63: Report Drill Down: Certificates by Key Strength Report

Figure 64: Report Drill Down: Certificate Search Results

# **List of Built-In Reports**

The following reports are available as part of the standard Keyfactor Command installation. Those marked with a (\*) have been configured to *Show in Navigator* by default, so they appear on the Management Portal top menu under Reports. The Report Manager page shows all the available reports.

- · Certificate Count by Template
- Certificate Count by User per Template
- · Certificate Count Grouped by Single Metadata Field
- · Certificate Issuance Trends with Metadata
- · Certificates by Key Strength
- · Certificates by Revoker
- · Certificates by Type and Java Keystores
- Certificates Found at TLS/SSL Endpoints
- Certificates in Collection (\*)
- Expiration Report (\*)
- Expiration Report by days (\*)
- Full Certificate Extract (\*)
- · Issued Certificates per Certificate Authority
- · Monthly Executive Report
- PKI Status for Collection (\*)
- Revoked Certificates in Certificate Stores
- · SSH Key Usage Report
- · SSH Keys by Age
- SSH Keys with Root Logon Access
- · SSH Trusted Public Keys with No Known Private Keys
- Statistical Report (\*)

## 2.1.4.1 Certificate Count by Template

The Certificate Count by Template report includes bar graphs showing the number of certificates issued, failed and revoked by template in the selected date range for the selected CA(s). Separate graphs are generated for issued and revoked certificates and for each selected CA. Each graph contains all the templates that have had certificates issued or revoked for the period.

**Note**: Clicking on a bar on the graph, or a section of a pie chart or line graph, will open a new window as a drill down to the certificate search grid filtered for the exact criteria of that aspect of the graph. You can return to the original report by navigating to the original report window.

#### Certificate Count by Template

Figure 65: Certificate Count by Template: Issued Certificates

The export options for the Certificate Count by Template report are Excel and PDF.

The input parameters for this report are:

- The start date and end date for the report date range. The default date range is 30 days prior through the current date, meaning only certificates issued and revoked in that date range will be included in the report.
- The CA(s) to include in the report. Templates that are available for issuance from more than one CA are reported separately by CA.

Note: Only CAs configured for synchronization are available for reporting.

**Note**: By default, this report is configured not to appear on the top menu under Reports and can be found only in Report Manager. You can change this by modifying the *Show in Navigator* setting (see Report Manager Operations on page 127).

## 2.1.4.2 Certificate Count by User per Template

The Certificate Count by User per Template report includes a table and bar graphs.

The bar graphs show the number of certificates issued by the certificate requester and template in the selected date range for the selected template(s). The report shows one bar for each requester and template combination; for example, KEYEXAMPLE\jsmith - Template One would be one bar and KEYEXAMPLE\mignes - Template One would be another bar.

**Note**: Clicking on a bar on the graph, or a section of a pie chart or line graph, will open a new window as a drill down to the certificate search grid filtered for the exact criteria of that aspect of the graph. You can return to the original report by navigating to the original report window.

#### Certificate Count by User per Template From 8/22/2022 (UTC) to 9/22/2022 (UTC) KEYEXAMPLE\mjones - Enterprise Web Server (2016) KEYEXAMPLE\qqant - Enterprise Web Server KEYEXAMPLE\ismith - Enterprise Web Server - RA KEYEXAMPLE\ismith - Enterprise Web Server (2016) User - Template Name Most Recent Requests (Max 100) Certificate CN Cert Store Location websrvr87.keyexample.com 8E237C2AB91E8E61B766F2C87EE7F353D184FD99 KEYEXAMPLE\ggant 9/22/2022 5:20 PM KEYEXAMPLE\()smith 9/22/2022 4:12 PM appsrvr13.kevexample.com 342967A1CBFB5626F067CDD54E5BA49397EF1241 9/22/2022 2:20 PM KEYEXAMPLE\smith Enterprise Web Server (2016) 9/22/2022 12:14 appsrvr12.keyexample.com 43C7F7C86A49ED05725D005747052A7F8C3C9F5F ns3.kevexample.com - /nsconfig/ssl 9/22/2022 12:06 websrvr93.keyexample.com AA5ADBDB41EB22BE0363B646DA46262C1A0357D3 KEYEXAMPLE\smith Ra websrvr93.keyexample.com - IIS Personal

Figure 66: Certificate Count by User by Template

The table shows detailed information for the certificates issued in the selected time-frame (up to a maximum of 100).

The export options for the Certificate Count by User per Template report are Excel and PDF. The PDF exports in landscape format to accommodate the width of the report.

The certificate details grid includes these fields:

- Issued Date
  The certificate's effective date.
- Certificate CN
   Common name of the certificate.
- Thumbprint
  Thumbprint of the certificate.
- User Name
   The user who requested the certificate. In some cases (e.g. enrollment using the Restrict Allowed Requesters option), this will be a service account rather than an end user.
- Template Name

  Name of the template used for the certificate.
- SSL Network
   The name of the SSL network containing the endpoint at which the certificate is found, if any.
- Cert Store Location
   The certificate store or stores in which the certificate is found, if any.

The input parameters for this report are:

The template names on which to report. Although you can select multiple templates, selecting
more than one or two templates can make for a messy report, depending on how many unique
users have requested certificates using the selected template(s) in the date range. Defaults for
the template(s) on which to report can be configured in the report parameters (see <a href="Report\_Manager Operations on page 127">Report\_Manager Operations on page 127</a>).

- The start date and end date for the date range on which to report. The default date range is one month ending with the current date. These defaults can be changed in the report parameters (see Report Manager Operations on page 127).
- A requester and template combination bar will only be included in the bar chart, with corresponding details in the details grid, if the number of certificates issued for it in the selected date range exceeds the value selected for Certificate count more than.

**Example:** You want to track down instances of duplicate certificates where user X has been issued a certain type of certificate more than once and more than one of these certificates is still valid (not revoked). To use this report for that, select the template or templates used for that particular type of certificate (say, a client authentication template), select a date range that would cover the full lifetime for certificates issued by that template, and select a value of 1 or greater in the *Certificate count more than* field. The report results will include all users who have multiple certificates issued with the selected template(s) in the selected date range.

**Note:** Certificates must have a certificate state of *Active* to be included in the report. The report output includes active and expired certificates but not revoked certificates.

**Note**: By default, this report is configured not to appear on the top menu under Reports and can be found only in Report Manager. You can change this by modifying the *Show in Navigator* setting (see Report Manager Operations on page 127).

## 2.1.4.3 Certificate Count Grouped by Single Metadata Field

The Certificate Count Grouped by Single Metadata Field report includes a data table with two columns:

- Metadata Value
   All the populated values for the selected metadata field for certificates issued in the selected date range.
- Certificate Count
   The number of certificates issued for each metadata value in the selected date range.

For example, if the selected metadata field is AppOwnerEmailAddress, the table will show a row for each unique email address populated in a certificate issued in the selected date range with a count of how many certificates share that same email address.

## Certificate Count Grouped by Single Metadata - AppOwnerEmailAddress

Export

martha.jones@keyexample.com	21		
zed.adams@keyexample.com	26		

Figure 67: Certificate Count Grouped by Single Metadata Field

The export options for the Certificate Count Grouped by Single Metadata Field report are CSV, Excel, and PDF.

The input parameters for this report are:

- The metadata field on which to report. Only Boolean, integer, multiple choice, and string fields are available for reporting.
- The start date and end date for the date range on which to report. The default date range is one month ending with the current date. Only certificates issued within the time span will be counted.

**Note**: Certificates must have a certificate state of *Active* to be included in the report. The report output includes active and expired certificates but not revoked certificates. Only certificates issued within the time span will be counted.

**Note**: By default, this report is configured not to appear on the top menu under Reports and can be found only in Report Manager. You can change this by modifying the *Show in Navigator* setting (see Report Manager Operations on page 127).

## 2.1.4.4 Certificate Issuance Trends with Metadata

The Certificate Issuance Trends with Metadata report produces tables and pie charts showing currently active certificates based on the selected input parameters as follows: the number of certificates per requester and the number of certificates per metadata value for each of the metadata fields chosen, based on the certificate collection chosen. Multiple tables and charts will be produced when the report is generated.

**Note**: Clicking on a bar on the graph, or a section of a pie chart or line graph, will open a new window as a drill down to the certificate search grid filtered for the exact criteria of that aspect of the graph. You can return to the original report by navigating to the original report window.

Figure 69: Certificate Issuance Trends with Metadata: Metadata Table and Chart

The export options for the Certificate Issuance Trends with Metadata report are Excel and PDF.

**Note:** When either scheduling or exporting this report as an Excel file, the output will not include the graphs.

The input parameters for this report are:

- Collections: The name of the collection to report on.
- The start date and end date for the report: The definition of the date range for the report.
- Metadata: Check a metadata field from the pop-up to select it for this report.
- Requesters: A comma-separated list of requester user names (do not included the domain name).

**Tip:** If you **Save** a new certificate collection, or **Save** a change to an existing certificate collection, that change will be immediately reflected in the collection data used to display

certificate collections on dashboards and reports. The data used by the dashboards and reports is stored in an intermediate table that is updated immediately. It will also continue to be updated periodically (approximately every 20 minutes by default as configured by the *Dashboard Collection Caching Interval* application setting) by the Keyfactor Command Service (see Application Settings: Console Tab on page 603).

**Note**: By default, this report is configured not to appear on the top menu under Reports and can be found only in Report Manager. You can change this by modifying the *Show in Navigator* setting (see Report Manager Operations on page 127).

**Note**: Other than the option of certificates with no associated CA, only CAs currently configured for synchronization are available for reporting.

## 2.1.4.5 Certificates by Key Strength

The Certificates by Key Strength report includes a bar graph showing the number of active certificates by key strength (e.g. sha-1, sha-256) for the selected CA(s), a bar graph showing the number of active certificates by key size for the selected CA(s), and a pie chart for each selected CA showing the active certificates by key size (e.g. 1024 bit, 2048 bit).

**Note**: Clicking on a bar on the graph, or a section of a pie chart or line graph, will open a new window as a drill down to the certificate search grid filtered for the exact criteria of that aspect of the graph. You can return to the original report by navigating to the original report window.

Active Certificates by Key Size for HQIssuingCA1

Figure 70: Certificates by Key Strength

The export options for the Certificates by Key Strength report are Excel and PDF.

This report takes as an input parameter the CA(s) on which to report and includes the option to report on certificates that have no associated CA. Typically, these would be certificates found via SSL scanning or inventory on certificate stores.

**Note**: Other than the option of certificates with no associated CA, only CAs currently or previously configured for synchronization are available for reporting.

### 2.1.4.6 Certificates by Revoker

The Certificates by Revoker report includes a bar graph showing the number of certificates revoked through Keyfactor Command in the selected date range for the selected CA(s) broken down by the user doing the revocation. The report shows one bar for each revoker.

**Note**: Clicking on a bar on the graph, or a section of a pie chart or line graph, will open a new window as a drill down to the certificate search grid filtered for the exact criteria of that aspect of the graph. You can return to the original report by navigating to the original report window.

Figure 71: Certificates by Revoker

The export options for the Certificates by Revoker report are Excel and PDF.

**Note**: Certificates that have been revoked outside of Keyfactor Command (e.g. directly on the CA) appear with an *Unknown* revoker.

The input parameters for this report are:

• The evaluation date for the report. This report covers a specified number of days, weeks or months ending with this date. The default evaluation date is the current date, meaning

certificates revoked up to the current date will be included in the report. The default can be changed in the report parameters (see Report Manager Operations on page 127).

- The number of periods to include in the report. This is how many days, weeks or months of data to include in the report. The default is 52.
- The period length for the report. The options are days, weeks or months. The default is weeks.
- The CA(s) to include in the report. Certificates that were issued from CA(s) other than those selected will not be included in the counts of revoked certificates.

**Note**: By default, this report is configured not to appear on the top menu under Reports and can be found only in Report Manager. You can change this by modifying the *Show in Navigator* setting (see Report Manager Operations on page 127).

**Note:** Only CAs currently or previously configured for synchronization are available for reporting.

## 2.1.4.7 Certificates by Type and Java Keystore

The Certificates by Type and Java Keystore report provides a table with a summary of the number of certificates generated through Keyfactor Command in the selected date range broken down by PFX requests versus CSR requests for a selected CA or CAs. In addition, a count is provided of certificates that were added to Java Keystores in this timeframe (new or existing certificates from any source).

## Certificates by Type and Java Keystores

## Count of Issued PFX/CSR Certificates and JKS Additions

For CorplssuingCA1, HQIssuingCA1

From 8/23/2022 to 9/22/2022

PFX Count	JKS Count	CSR Count
24	2	3

Figure 72: Certificates by Type and Java Keystore

The export options for the Certificates by Type and Java Keystore report are Excel and PDF.

The input parameters for this report are:

- The CA(s) to include in the report. Certificates that were issued from CAs other than those selected will not be included in the counts of PFXs and CSRs.
- The start date and end date for the date range on which to report. The default date range is one month ending with the current date. These defaults can be changed in the report parameters

(seeReport Manager Operations on page 127).

**Note**: By default, this report is configured not to appear on the top menu under Reports and can be found only in Report Manager. You can change this by modifying the *Show in Navigator* setting (see Report Manager Operations on page 127).

**Note:** Only CAs currently or previously configured for synchronization are available for reporting.

## 2.1.4.8 Certificates Found at TLS/SSL Endpoints

The Certificates Found at TLS/SSL Endpoints report provides a table which shows the IP Address and Port for any discovered endpoints with the Issued DN for the certificate or certificates discovered at the endpoint and the server name indication (SNI) configured on the endpoint, if available. The report table includes these fields:

- IP Address
- Port
- Issued DN
- SNI Name
- Reverse DNS

## Certificates Found at TLS/SSL Endpoints

Ip Address	Port	Issued DN	SNI Name	Reverse DNS
10.15.20.2	443	CN=pfSense-619d0859492a1,O=pfSense webConfigurator Self-Signed Certificate		10.15.20.2

Figure 73: Certificates Found at TLS/SSL Endpoints

The export options for the Certificates Found at TLS/SSL Endpoints report are CSV and Excel.

The input parameters for this report are:

- The orchestrator pool on which to report. Only one orchestrator pool can be selected. A default for the orchestrator pool on which to report can be configured in the report parameters (see Report Manager Operations on page 127).
- The start date and end date for the date range on which to report. The default date range is one month ending with the current date. These defaults can be changed in the report parameters (see Report Manager Operations on page 127).

#### 2.1.4.9 Certificates in Collection

The Certificates in Collection report shows detailed information for the active, expired and revoked certificates in the selected collection.

**Tip:** If you **Save** a new certificate collection, or **Save** a change to an existing certificate collection, that change will be immediately reflected in the collection data used to display certificate collections on dashboards and reports. The data used by the dashboards and reports is stored in an intermediate table that is updated immediately. It will also continue to be updated periodically (approximately every 20 minutes by default as configured by the *Dashboard Collection Caching Interval* application setting) by the Keyfactor Command Service (see <u>Application Settings: Console Tab on page 603</u>).

The export options for the Certificates in Collection report are CSV and Excel.

The report table includes these fields:

ID

The Keyfactor Command reference ID for the certificate.

- Issued DN
- Effective Date (UTC)
- Expiration Date (UTC)
- Issued CN
- Issuer DN
- Principal

The user principal name (UPN) contained in the subject alternative name (SAN) field of the certificate, if present (e.g. username@keyexample.com).

- Requester
- Thumbprint
- Template
- Cert State

The state of the certificate (e.g. Active, Revoked, Unknown).

- Key Type
- · Key Size in Bits
- Key Usage
- Signing Algorithm
- Serial Number
- CA Record ID

The ID of the certificate in the CA database.

Issued OU

The OU from the certificate subject, if any.

Issued Email

The email address from the certificate subject, if any.

- · Revocation Effective Date
- Revocation Reason
- · Metadata (Optional)

Column handling on this report grid has the following features:

- To change the width of a column of the report, hover over the triangle of dots on the right side of the selected column header (☑). Click, hold and drag the triangle to change the width of the column.
- To rearrange columns on the report display, hover over the rectangle of dots on the left side of the selected column header (!!). Click, hold, and drag the rectangle to move the column to your selected location.
- Most columns can be sorted in ascending order by clicking on the header of the column. Click
  the column header again to reverse the sort order. When a column is sorted, a caret will appear
  at the end of the column name showing the direction of the sort. Lack of a triangle indicates the
  report is sorted by the default column and order.

The input parameter for this report is:

- The certificate collection to report on, including the built-in option, *All Certificates* collection. The default is *All Certificates*.
- The metadata field(s) to include, if desired.

## 2.1.4.10 Expiration Report

The Expiration Report includes table(s) showing detailed information for certificates expiring and expired within the next 12 weeks and CA certificates expiring and expired within the next 2 1/2 years. Expired certificates are only included if they have expired within the last 4 weeks.

**Expiration Report - Key PKI Certificates** 

Export

Expiration Report for 9/22/2022

Figure 74: Certificate Expiration Report: Certificates Expiring within One Week

The export options for the Expiration report are Excel and PDF. The PDF exports in landscape format to accommodate the wide width of the report.

The report includes the following tables:

- Expired Certificates (within the last 4 weeks)
- Certificates less than 1 week from expiration
- Certificates less than 2 weeks from expiration
- · Certificates less than 4 weeks from expiration
- Certificates less than 6 weeks from expiration
- Certificates less than 8 weeks from expiration
- Certificates less than 12 weeks from expiration

In addition, tables are shown for CA certificates expiring in the following timeframes relative to the selected report date:

- CA certificates less than 6 months from expiration
- CA certificates less than 12 months from expiration
- CA certificates less than 18 months from expiration
- CA certificates less than 24 months from expiration
- CA certificates less than 30 months from expiration

A table is only shown if a certificate or CA in the collection matches the expiration time window. A certificate or CA appears in only one table, so, for example, a certificate expiring within 4 weeks does not also appear as expiring within 6 weeks.

The report tables include these fields:

- CN (Common Name)
- Template
- Issued On
- Expires On (this is the default sort order)
- · Requested By
- Thumbprint
- Serial (Number)
- Issuer (Distinguished Name)
- Metadata (optional)

Column handling on this report grid has the following features:

- To change the width of a column of the report, hover over the triangle of dots on the right side of the selected column header (). Click, hold and drag the triangle to change the width of the column.
- To rearrange columns on the report display, hover over the rectangle of dots on the left side of the selected column header ( ). Click, hold, and drag the rectangle to move the column to your selected location.
- Most columns can be sorted in ascending order by clicking on the header of the column. Click
  the column header again to reverse the sort order. When a column is sorted, a caret will appear
  at the end of the column name showing the direction of the sort. Lack of a triangle indicates the
  report is sorted by the default column and order.

The input parameters for this report are:

- The certificate collection to report on, including the built-in *All Certificates* collection. The default is *All Certificates*.
- The evaluation date to report on. The default is the current date.
- The metadata field(s) to include, if desired.

Tip: This report makes use of the optional certificate de-duplication logic by default. When de-duplication is enabled for a report, the report results will include only the most recently issued certificate if there is more than one certificate that matches the de-duplication criteria. De-duplication is enabled for a report by checking the Ignore Renewed Certificates box on the Details tab of the report configuration (see Report Manager Operations on page 127). De-duplication can only be enabled for reports that use certificate collections the Uses Collection box on the Details tab. The Uses Collection setting is not user-configurable.

De-duping is configured on a certificate collection by setting the Ignore renewed certificate results by option when saving a certificate collection (see Saving Search Criteria as a Collection on page 43). Certificate collections may be configured to be de-duplicated based on the certificate common name, distinguished name, or principal name (or not at all). Only certificates that share all the EKUs (e.g. Client Authentication and Server Authentication) as well as the same CN, DN or UPN will be eliminated as duplicates. If a certificate has more than one EKU and at least one EKU does not match an otherwise similar certificate with matching CN, DN or UPN, it will not be eliminated.

For example, if the de-duplication logic was set to DN and the report would include these two certificates:

- · Certificate one:
  - DN: CN=appssrvr14.keyexample.com,OU=IT,O=Key Example, Inc.,L=Chicago,ST=IL,C=US
  - EKUs: Server Authentication
  - Issued Date: December 1, 2020
  - Expiration Date: January 1, 2022

- · Certificate two:
  - DN: CN=appssrvr14.keyexample.com,OU=IT,O=Key Example, Inc.,L=Chicago,ST=IL,C=US
  - · EKUs: Server Authentication
  - Issued Date: December 15, 2020
  - Expiration Date: December 14, 2021

The de-duplication logic would be triggered because the DNs and EKUs match. The report would include certificate two and leave out certificate one. Notice that certificate two is retained even through certificate one expires after certificate two. This is because certificate two was issued after certificate one.

Now imagine that the de-duplication logic is set to CN and the report would include these two certificates:

- · Certificate one:
  - DN-CN=appsrvr14.keyexample.com,OU= IT,O=Key Example, Inc.,L-L=Chicago,ST=IL,C=US
  - EKUs: Server Authentication
  - Issued Date: December 1, 2020
  - Expiration Date: January 1, 2022

- · Certificate two:
  - DN: CN=appsrvr14.keyexample.com,OU= HR,O=Key Example, Inc.,L-L=Chicago,ST=IL,C=US
  - EKUs: Server Authentication, Client Authentication
  - Issued Date: December 15, 2020
  - Expiration Date: December 14, 2021

Although the DNs for these certificates do not match, the CNs still do, so this matches the deduplication logic of CN. However, the EKUs for these two certificates do not match, since only one of them includes Client Authentication. In this case, both certificates would appear on the report.

Note: This report is limited to a maximum of 10,000 expiring and recently expired (within the last 4 weeks) certificates on which to report. Selecting a certificate collection containing more expiring and recently expired certificates than this, based on the evaluation date, will result in an error. Selecting a certificate collection containing a large number of certificates to report on can cause the report to take a long time to generate.

## 2.1.4.11 Expiration Report by Days

The Expiration Report by Days shows details for certificates expiring after a given start date with a time span chosen in days. It can be used, for example, to show you all the certificates in a certificate collection expiring within the next few days.

The Expiration Report includes a table showing detailed information for certificates expiring in the time frames identified by the parameters start date and number of days. The number of days parameter value must be between 0 and 100.

The export options for the Expiration Report by Days are CSV and Excel.

The report tables include these fields:

- CN (Common Name)
- Template
- Issued On
- Expires On (this is the default sort order)
- Requested By
- Thumbprint
- Serial (Number)
- Issuer (Distinguished Name)
- Metadata (optional)

Column handling on this report grid has the following features:

- · To change the width of a column of the report, hover over the triangle of dots on the right side of the selected column header 📳 . Click, hold and drag the triangle to change the width of the column.
- To rearrange columns on the report display, hover over the rectangle of dots on the left side of the selected column header (!!!). Click, hold, and drag the rectangle to move the column to your selected location.

• Most columns can be sorted in ascending order by clicking on the header of the column. Click the column header again to reverse the sort order.

The input parameters for this report are:

- The certificate collection to report on, including the built-in *All Certificates* collection. The default is *All Certificates*.
- The start date of the reporting period. The default is the current date.
- The number of days in the reporting period (must be between 0 and 100). The default is 6.
- The metadata field(s) to include, if desired.

**Tip:** If you **Save** a new certificate collection, or **Save** a change to an existing certificate collection, that change will be immediately reflected in the collection data used to display certificate collections on dashboards and reports. The data used by the dashboards and reports is stored in an intermediate table that is updated immediately. It will also continue to be updated periodically (approximately every 20 minutes by default as configured by the *Dashboard Collection Caching Interval* application setting) by the Keyfactor Command Service (see <u>Application Settings: Console Tab on page 603</u>).

**Tip:** This report makes use of the optional certificate de-duplication logic by default. When de-duplication is enabled for a report, the report results will include only the most recently issued certificate if there is more than one certificate that matches the de-duplication criteria. De-duplication is enabled for a report by checking the *Ignore Renewed Certificates* box on the Details tab of the report configuration (see <a href="Report Manager Operations on page 127">Report Manager Operations on page 127</a>). De-duplication can only be enabled for reports that use certificate collections—the *Uses Collection* box on the Details tab. The *Uses Collection* setting is not user-configurable.

De-duping is configured on a certificate collection by setting the *Ignore renewed certificate results by* option when saving a certificate collection (see <u>Saving Search Criteria as a Collection on page 43</u>). Certificate collections may be configured to be de-duplicated based on the certificate common name, distinguished name, or principal name (or not at all). Only certificates that share all the EKUs (e.g. Client Authentication and Server Authentication) as well as the same CN, DN or UPN will be eliminated as duplicates. If a certificate has more than one EKU and at least one EKU does not match an otherwise similar certificate with matching CN, DN or UPN, it will not be eliminated.

For example, if the de-duplication logic was set to DN and the report would include these two certificates:

- · Certificate one:
  - DN: CN=appssrvr14.keyexample.com,OU=IT,O=Key Example, Inc.,L=Chicago,ST=IL,C=US
  - EKUs: Server Authentication
  - Issued Date: December 1, 2020
  - Expiration Date: January 1, 2022

- Certificate two:
  - DN: CN=appssrvr14.keyexample.com,OU=IT,O=Key Example, Inc.,L=Chicago,ST=IL,C=US
  - EKUs: Server Authentication
  - Issued Date: December 15, 2020
  - Expiration Date: December 14, 2021

The de-duplication logic would be triggered because the DNs and EKUs match. The report would include certificate two and leave out certificate one. Notice that certificate two is retained even through certificate one expires after certificate two. This is because certificate two was issued after certificate one.

Now imagine that the de-duplication logic is set to CN and the report would include these two certificates:

- · Certificate one:
  - DN: CN=appsrvr14.keyexample.com,OU= IT,O=Key Example, Inc.,L-L=Chicago,ST=IL,C=US
  - EKUs: Server Authentication
  - Issued Date: December 1, 2020
  - Expiration Date: January 1, 2022

- Certificate two:
  - DN: CN=appsrvr14.keyexample.com,OU= HR,O=Key Example, Inc.,L-L=Chicago,ST=IL,C=US
  - EKUs: Server Authentication, Client Authentication
  - Issued Date: December 15, 2020
  - Expiration Date: December 14, 2021

Although the DNs for these certificates do not match, the CNs still do, so this matches the deduplication logic of CN. However, the EKUs for these two certificates do not match, since only one of them includes Client Authentication. In this case, both certificates would appear on the report.

Note: This report is limited to a maximum of 10,000 expiring certificates on which to report. Selecting a certificate collection containing more expiring certificates than this, within the selected reporting period, will result in an error. Selecting a certificate collection containing a large number of certificates to report on can cause the report to take a long time to generate.

### 2.1.4.12 Full Certificate Extract Report

The Full Certificate Extract Report shows detailed information for the active, expired and revoked certificates in the selected collection.

The export options for the Full Certificate Extract Report are CSV and Excel.

The report table includes these fields:

- Common Name
  - The common name of the certificate.
- Valid From
  - The date on which the certificate became valid (typically the issuance date).
- Valid To

The date on which the certificate expires.

- Total SANs
  - The total number of subject alternative names (SANs) for the certificate.
- SANs
  - Any subject alternative names (SANs) of type DNS name, UPN, or email.
- SANs IP

Days to Expiration

The number of days remaining until the certificate expires. This will be a negative value for expired certificates.

· Signature Algorithm

The cryptographic algorithm used to sign the certificate.

· Key Size

The key length used to create the certificate.

· Validity Period

The number of days for which the certificate was issued.

Serial Number

The serial number of the certificate.

DN

The distinguished name (subject) of the certificate.

Issuer DN

The distinguished name of the issuer (CA) for the certificate.

User Name

The name of the identity that requested the certificate.

Any subject alternative names (SANs) of type IP address.

Port

The port where the certificate was found on an SSL scan.

IP Address

The IP address where the certificate was found on an SSL scan.

DNS Name

The DNS name resolved for the IP address where the certificate was found on an SSL scan.

Alias

The alias of the certificate in the certificate store.

Client Machine

Depending on the type of certificate store, either the name of the server on which the orchestrator is installed or the name of the server on which the certificate store is located.

· Store Path

The location of the certificate store. The format of this value will vary depending on the type of certificate store.

• Template

The certificate template used to issue the certificate.

Column handling on this report grid has the following features:

- To change the width of a column of the report, hover over the triangle of dots on the right side of the selected column header (☑). Click, hold and drag the triangle to change the width of the column.
- To rearrange columns on the report display, hover over the rectangle of dots on the left side of the selected column header (!!). Click, hold, and drag the rectangle to move the column to your selected location.
- Most columns can be sorted in ascending order by clicking on the header of the column. Click the column header again to reverse the sort order.

This report takes the input parameters:

- The certificate collection to report on, including the built-in option, *All Certificates* collection. The default is *All Certificates*.
- The metadata field(s) to include, if desired. This will append the selected metadata columns to the end of the report.

Tip: If you **Save** a new certificate collection, or **Save** a change to an existing certificate collection, that change will be immediately reflected in the collection data used to display certificate collections on dashboards and reports. The data used by the dashboards and reports is stored in an intermediate table that is updated immediately. It will also continue to be updated periodically (approximately every 20 minutes by default as configured by the *Dashboard Collection Caching Interval* application setting) by the Keyfactor Command Service (see Application Settings: Console Tab on page 603).

## 2.1.4.13 Issued Certificates per Certificate Authority

The Issued Certificates per Certificate Authority report includes line graphs showing the number of certificates issued for each template in the selected date range for the selected template(s) on the selected CA. A separate line graph is generated for each template. An option to report on certificates that are not associated with any CA is included.

**Note**: Clicking on a bar on the graph, or a section of a pie chart or line graph, will open a new window as a drill down to the certificate search grid filtered for the exact criteria of that aspect of the graph. You can return to the original report by navigating to the original report window.

Figure 75: Issued Certificates per CA

The export options for the Issued Certificates per Certificate Authority report are Excel and PDF.

The input parameters for this report are:

- The evaluation date for the report. This report covers a specified number of days, weeks or months ending with this date. The default evaluation date is the current date, meaning certificates issued up to the current date will be included in the report.
- The number of periods to include in the report. This is how many days, weeks or months of data to include in the report. The default is 6.
- The period length for the report. The options are days, weeks or months. The default is weeks.

- Which CA to include in the report. This includes the option to report on certificates that have no associated CA. Typically, these would be certificates found via SSL scanning or inventory on certificate stores. Only one CA option can be reported on at a time.
- The template(s) to include in the report. A separate line graph is generated for each template selected for reporting. Templates that are available for issuance from more than one CA are reported separately by CA, so only certificates issued for the selected template and the selected CA will be shown. When the Certificates Not Associated with CA option is selected for the CA, the No Template option should be selected for the template.

**Note**: Other than the option of certificates with no associated CA, only CAs currently configured for synchronization are available for reporting.

## 2.1.4.14 Monthly Executive Report

The Monthly Executive report provides a dashboard-like summary including bar and pie charts with counts of certificates created, renewed and approaching expiration for a selected CA or CAs. Data for certificates approaching expiration is presented in a pie chart broken out into certificates that will expire in the next 15 days, in 16-30 days, 31-60 days and 61-90 days. Data for certificates that have been recently created or renewed is presented in a bar chart that includes data for the current month and the previous month, broken out by month and renewed versus newly created. In addition, a summary pie chart is included that shows all the active certificates for the selected CAs broken out by CA.

**Note**: Clicking on a bar on the graph, or a section of a pie chart or line graph, will open a new window as a drill down to the certificate search grid filtered for the exact criteria of that aspect of the graph. You can return to the original report by navigating to the original report window.

The export options for the Monthly Executive report are Excel and PDF.

## Certificates by Days to Expiration: CorplssuingCA1

Figure 76: Example Pie Chart from Monthly Executive Report

This report takes as an input parameter the CA or CAs to report on and includes the option to report on certificates that have no associated CA. Typically, these would be certificates found via SSL scanning or inventory on certificate stores.

**Note**: By default, this report is configured not to appear on the top menu under Reports and can be found only in Report Manager. You can change this by modifying the *Show in Navigator* setting (see Report Manager Operations on page 127).

**Note:** Only CAs currently or previously configured for synchronization are available for reporting.

#### 2.1.4.15 PKI Status for Collection

The PKI Status for Collection report is a multi-page report incorporating tables and charts that provides an overview of the status of the certificates in the selected collection.

**Note**: Clicking on a bar on the graph, or a section of a pie chart or line graph, will open a new window as a drill down to the certificate search grid filtered for the exact criteria of that aspect of the graph. You can return to the original report by navigating to the original report window.

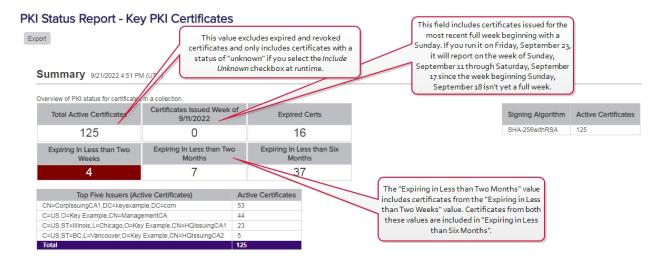

Figure 77: PKI Status for Collection Summary

The export options for the PKI Status for Collection report are Excel and PDF.

This report takes as an input parameter the certificate collection to report on, including the built-in *All Certificates* collection, and has the option to include or exclude certificates that have a status of unknown (certificates found on SSL scans and in certificate stores often have this status). The default collection is *All Certificates*, and unknown certificates are excluded by default.

**Tip:** If you **Save** a new certificate collection, or **Save** a change to an existing certificate collection, that change will be immediately reflected in the collection data used to display certificate collections on dashboards and reports. The data used by the dashboards and reports is stored in an intermediate table that is updated immediately. It will also continue to be updated periodically (approximately every 20 minutes by default as configured by the *Dashboard Collection Caching Interval* application setting) by the Keyfactor Command Service (see <u>Application Settings: Console Tab on page 603</u>).

Sections of the report include:

## **Summary Page**

The summary page provides certificate counts for the following:

- · Total number of active certificates
  - This value excludes expired and revoked certificates and only includes non-expired, non-revoked certificates with an unknown state if the *Include Unknown* checkbox is selected at runtime.
- Number of certificates issued in the most recently completed week, beginning with a Sunday
- Number of expired certificates
- · Number of certificates coming up for expiration within two weeks

- Number of certificates coming up for expiration within two months (including those expiring within two weeks)
- Number of certificates coming up for expiration within six months (including those expiring within two weeks and two months)
- A breakdown of the number of active certificates by signing algorithm (only the top five signing algorithms are shown)
- The top five issuers of active certificates with the number of active certificates

# **Next Ten Certificates to Expire Page**

This table shows details of the ten certificates expiring within the shortest timeframe (for any timeframe under two years) and includes the certificate CN, issuer CN, certificate validity period in UTC time, template name, thumbprint and serial number. Grid columns may be rearranged by clickholding and dragging the grid arrangement control icon () at the left of the column header. Click a column header to sort the grid by ascending values; click again to sort descending (columns already in ascending order will switch to descending on the first click). The screen will redraw when you sort. Not all columns are sortable.

## PKI Health Metrics—Lifetime Remaining Page

This donut chart shows the percentage of certificates that are expired, near expiration (90% or more of lifetime used) or active and not near expiration along with a table showing the specific numbers in these categories. Hover over a segment in the donut chart to see details for that segment. Click one of the labels below the donut chart to toggle add/remove the segment on the chart. Grid columns may be rearranged by click-holding and dragging the grid arrangement control icon (3) at the left of the column header. Click a column header to sort the grid by ascending values; click again to sort descending (columns already in ascending order will switch to descending on the first click). The screen will redraw when you sort. Not all columns are sortable.

 TableRating
 Total Certificates

 Adequate
 16

 Near Expiration
 1

 Expired
 1

The Certificate Lifetime Remaining shows the percentage of certificates that are expired, near expiration, or that have plenty of time before they're expired. It also shows how many certificates fall into each category:
Adequate, Near Expiration, and Expired. This gives insight into how many certificates need ettention; certificates near expiration pose a risk of outage.

Figure 78: PKI Status for Collection Lifetime Remaining

## PKI Health Metrics—Algorithm Strength

This donut chart shows the percentage of certificates (active and expired) with strong (SHA2 and SSA), weak (SHA1) or critically weak (MD5 and older) signature algorithms along with a table showing the specific numbers in these categories. Hover over a segment in the donut chart to see details for that segment. Click one of the labels below the donut chart to toggle add/remove the segment on the chart. Grid columns may be rearranged by click-holding and dragging the grid arrangement control icon (B) at the left of the column header. Click a column header to sort the grid by ascending values; click again to sort descending (columns already in ascending order will switch to descending on the first click). The screen will redraw when you sort. Not all columns are sortable.

# PKI Health Metrics—RSA Key Strength

This donut chart shows the percentage of certificates (active and expired) with strong (2048+), weak (1024-2047), and critically weak (<1024) RSA keys along with a table showing the specific numbers in these categories. Hover over a segment in the donut chart to see details for that segment. Click one of the labels below the donut chart to toggle add/remove the segment on the chart. Grid columns may be rearranged by click-holding and dragging the grid arrangement control icon (3) at the left of the column header. Click a column header to sort the grid by ascending values; click again to sort descending (columns already in ascending order will switch to descending on the first click). The screen will redraw when you sort. Not all columns are sortable.

# **Certificates by Signing Algorithm**

This donut chart shows the percentage of active certificates broken down by signing algorithm (RSA SHA-1, RSA SHA-256, etc.) along with a table showing the specific numbers in these categories. Hover over a segment in the donut chart to see details for that segment. Click one of the labels below the donut chart to toggle add/remove the segment on the chart.

## **Top Certificate Issuers**

This donut chart shows the percentage of certificates (active and expired) broken down by the top five issuers plus an *other* bucket along with a table showing the specific numbers in these categories. Hover over a segment in the donut chart to see details for that segment. Click one of the labels below the donut chart to toggle add/remove the segment on the chart. Grid columns may be rearranged by click-holding and dragging the grid arrangement control icon ( ) at the left of the column header. Click a column header to sort the grid by ascending values; click again to sort descending (columns already in ascending order will switch to descending on the first click). The screen will redraw when you sort. Not all columns are sortable.

Figure 79: PKI Status for Collection Top Issuers

#### **Certificates Issued in Previous 10 Weeks**

This bar chart shows the number of certificates (active and expired) issued per week for the ten weeks leading up to and through the full week prior to the run date of the report. Hover over a bar to see the number of issued certificates for the week with that date.

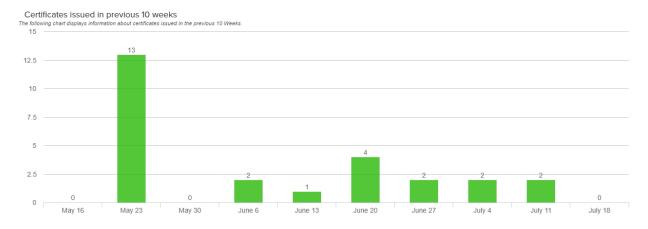

Figure 80: PKI Status for Certificates issued in previous 10 weeks

#### **Certificates Issued in Previous 12 Months**

This bar chart shows the number of certificates (active and expired) issued per month for the twelve months leading up to and through the full month prior to the run date of the report, broken down by internally issued certificates (from sources managed by Keyfactor Command such as synchronization of CAs in the primary forest and any trusted forests, any certificate vendors synced using a Keyfactor gateway, and any CAs synced using the remote CA agent) and externally issued certificates (from sources not managed by Keyfactor Command such as certificates located during SSL scans or uploaded using the Add Certificate option). Hover over a bar to see the number of issued certificates for that month and source. Click one of the labels below the chart to toggle add/remove the segment on the chart.

Figure 81: PKI Status for Certificates issued in previous 12 months

### Weak RSA Certificates

This table shows details of the certificates with weak (under 2048) RSA keys and includes the certificate CN, issuer CN, certificate validity period in UTC time, key size, thumbprint and serial number. A maximum of 1000 certificates is shown. Grid columns may be rearranged by click-holding and dragging the grid arrangement control icon (i) at the left of the column header. Click a column header to sort the grid by ascending values; click again to sort descending (columns already in ascending order will switch to descending on the first click). The screen will redraw when you sort. Not all columns are sortable.

# **Deprecated Signing Algorithms**

This table shows details of the certificates with deprecated (MD5 and older) signing algorithms and includes the certificate CN, issuer CN, certificate validity period in UTC time, signing algorithm, thumberint and serial number. A maximum of 1000 certificates is shown. Grid columns may be rearranged by click-holding and dragging the grid arrangement control icon ( ) at the left of the column header. Click a column header to sort the grid by ascending values; click again to sort descending (columns already in ascending order will switch to descending on the first click). The screen will redraw when you sort. Not all columns are sortable.

## **Self-Signed Certificates**

This table shows details of the certificates that are self-signed or root CA certificates and includes the certificate DN, certificate validity period in UTC time, thumbprint and serial number. A maximum of 1000 certificates is shown. Grid columns may be rearranged by click-holding and dragging the grid arrangement control icon ( ) at the left of the column header. Click a column header to sort the grid by ascending values; click again to sort descending (columns already in ascending order will switch to descending on the first click). The screen will redraw when you sort. Not all columns are sortable.

#### 2.1.4.16 Revoked Certificates in Certificate Stores

The Revoked Certificates in Certificate Stores report displays a table of all certificates that have been revoked, either in Keyfactor Command or externally, that are found in at least one certificate store or SSL scan location, and for which the revocation effective date is less than or equal to the date and time when the report is run (not in the future). The report is included in the report manager Certificate Locations and Certificate Lifecycle categories.

The export options for the Revoked Certificates in Certificate Stores report are CSV and Excel.

The report table includes these fields:

Certificate CN

The common name of the certificate.

• Thumbprint

The thumbprint of the certificate.

User

The username (DOMAIN\username format) of the user who revoked the certificate.

• Expiration Date (UTC)

The date on which the certificate expires.

• Issued Date (UTC)

The date on which the certificate became valid (typically the issuance date).

• Template Name

The certificate template used to issue the certificate.

SSL Location

The DNS name(s) resolved for the IP address(es) where the certificate was found on an SSL scan. Due to query constraints, the maximum length of text allowed in each of these fields is 10,000 characters.

· Cert Store Location

The name(s) of the server(s) on which the certificate is found in one or more certificate stores and the location of the certificate store(s). The format of this value will vary depending on the type of certificate store. Due to query constraints, the maximum length of text allowed in each of these fields is 10,000 characters.

Revocation Date (UTC)

The date on which the certificate was revoked in UTC.

· Revocation Reason

The reason given for the certificate revocation.

Revocation Comment
 The comment entered at revocation.

Column handling on this report grid has the following features:

- To change the width of a column of the report, hover over the triangle of dots on the right side of the selected column header (). Click, hold and drag the triangle to change the width of the column.
- To rearrange columns on the report display, hover over the rectangle of dots on the left side of the selected column header ( ). Click, hold, and drag the rectangle to move the column to your selected location.
- Most columns can be sorted in ascending order by clicking on the header of the column. Click
  the column header again to reverse the sort order. When a column is sorted, a caret will appear
  at the end of the column name showing the direction of the sort. Lack of a triangle indicates the
  report is sorted by the default column and order.

This report takes as an input parameter the certificate collection to report on, including the built-in *All Certificates* collection. The default is *All Certificates*.

Tip: If you **Save** a new certificate collection, or **Save** a change to an existing certificate collection, that change will be immediately reflected in the collection data used to display certificate collections on dashboards and reports. The data used by the dashboards and reports is stored in an intermediate table that is updated immediately. It will also continue to be updated periodically (approximately every 20 minutes by default as configured by the *Dashboard Collection Caching Interval* application setting) by the Keyfactor Command Service (see Application Settings: Console Tab on page 603).

**Note**: By default, this report is configured not to appear on the top menu under Reports and can be found only in Report Manager. You can change this by modifying the *Show in Navigator* setting (see Report Manager Operations on page 127).

**Note**: This report is limited to a maximum of 100,000 revoked certificates in certificate stores on which to report. Selecting a certificate collection containing more certificates than this will result in an error.

### 2.1.4.17 SSH Key Usage

The SSH Key Usage report shows a table which displays a list of SSH keys that have not been used to log on in the given minimum number of days.

The export options for the SSH Key Usage report are CSV and Excel.

The grid includes:

- Key Fingerprint
  The fingerprint of the SSH public key.
- Discovered Date
   The date and time (in local server time) on which the SSH key was discovered.
- Date Last Used
   The date and time (in local server time) on which the SSH key was last used.
- Key Length
   The key length of the SSH public key.
- Logon Username
   The Linux logon username associated with the key.
- Logon Server
   The IP address of the Linux server last used to logon.

This report takes as an input parameter; number of *Days Since Last Used*. You must select a number between 0 and 100.

## 2.1.4.18 SSH Keys by Age

The SSH Keys by Age report shows one or more table(s) with detailed information for SSH keys generated in Keyfactor Command broken down by age—as defined by the *Key Lifetime (days)* application setting (see Application Settings: SSH Tab on page 621).

The export options for the SSH Keys by Age report are PDF and Excel.

The report aging categories are:

- Stale keys (within the last 4 weeks)
- Keys less than 1 week from being stale
- · Keys less than 4 weeks from being stale
- · Keys less than 8 weeks from being stale
- · Keys less than 6 months from being stale
- · Keys less than 12 months from being stale

A table is only shown if an SSH key with one of the selected key types matches the age window. An SSH key appears only in one table, so, for example, a key that will become stale within 4 weeks and appears in the 4-week table does not also appear as becoming stale within the 8-week table.

### The grid includes:

Account Name

For user keys, the Active Directory user account associated with the key being reported on. For service account keys, the username and client hostname entered when the service account key was created (e.g. myapp@appsrvr.keyexample.com).

Creation Date

The date (in UTC time) on which the SSH key was created.

Fingerprint

The fingerprint of the SSH public key.

Key Type

The key type of the SSH public key.

Key Length

The key length of the SSH public key.

Associated Logons

The number of Linux logons associated with the SSH public key.

This report takes as an input parameter the SSH Key Types to include in the report. You must select at least one key type using the **Select SSH Key Types** button.

### 2.1.4.19 SSH Keys with Root Logon Access

The SSH Keys with Root Logon Access report shows a list of SSH public keys found associated with root logon authorized\_keys files on servers managed with the SSH orchestrator. Holders of the matching private keys for these public keys can gain root access without providing the root password.

The export options for the SSH Keys with Root Logon Access report are CSV and Excel.

The grid includes the fields:

- Account Name
  - The Active Directory user account associated with the key found to have root access on the target machine, if any. This field will only be populated for keys created in Keyfactor Command.
- Fingerprint
   The fingerprint of the SSH public key found associated with the root logon on the target machine.
- Hostname
  - The host name of the server on which the root logon was found to have an SSH public key providing logon access.
- · Creation Date
  - The date (in UTC time) on which the SSH key was created. This field will only be populated for keys created in Keyfactor Command.
- Date Found
  - The date (in UTC time) on which Keyfactor Command found the root logon SSH public key on the target server. This field will only be populated for keys discovered outside of Keyfactor Command (as opposed to created in Keyfactor Command).
- Key Type
  - The key type of the SSH public key found to have root access on the target machine.
- Key Length
  - The key length of the SSH public key found to have root access on the target machine.

The input parameter for this report is:

- The start date and end date range for the report. This is the date range during which SSH keys
  that allow root logon were created or discovered by Keyfactor Command. The default start date
  is one month prior to the current date. The default end date is the current date, meaning only
  SSH keys with root access discovered or created within the last month will be included in the
  report.
- The SSH Key Types to include in the report.

## 2.1.4.20 SSH Trusted Public Keys with No Known Private Keys

The SSH Trusted Public Keys with No Known Private Keys report shows a list of SSH public keys found in authorized\_keys files on servers managed with the SSH orchestrator that do not have a matching private key in Keyfactor Command.

The export options for the SSH Trusted Public Keys with No Known Private Keys report are CSV and Excel.

#### The grid includes:

- Logon Name
   The Linux user account associated with the SSH public key found on the target machine.
- Fingerprint
   The fingerprint of the SSH public key found associated with the referenced logon on the target machine.
- Date Found
   The date (in UTC time) on which Keyfactor Command found the SSH public key on the target machine.
- Key Type
   The key type of the SSH public key found on the target machine.
- Key Length
   The key length of the SSH public key found on the target machine.
- Hostname
   The host name of the server on which the root logon was found to have an SSH public key providing logon access.
- Server Group
   The server group to which the server on which the root logon was found belongs.

The input parameters for this report are:

- The start date and end date range for the report. This is the date range during which SSH keys
  were discovered by Keyfactor Command. The default start date is one month prior to the current
  date. The default end date is the current date, meaning only SSH keys that have no matching
  private key discovered within the last month will be included in the report.
- The SSH Key Types to include in the report. You must select at least one key type using the Select SSH Key Types button.

**Note**: By default, this report is configured not to appear on the top menu under Reports and can be found only in Report Manager. You can change this by modifying the *Show in Navigator* setting (see Report Manager Operations on page 127).

### 2.1.4.21 Statistical Report

The Statistical Report shows the number of issued, revoked, and failed (includes denied) certificates for a user-definable period of time leading up to a user-definable date broken down by CA, certificate template and reporting period length (day, week or month). The report includes sections titled "No Template Associated" for certificates with no associated template. This may be the case with certificates issued from a standalone CA as well as select failed certificate requests from enterprise CAs.

The export options for the Statistical Report are PDF and Excel.

## Statistical Report

corpca01.keyexample.com\CorplssuingCA1

Figure 82: Example Portion of the Statistical Report

The input parameters for this report are:

- The evaluation date of the reporting period. The default is the current date.
- The number of periods to report on. The default is six.

• The period length—day, week or month. The default is week.

Tip: The Total Active Certificates count for each CA section in the report includes all certificates issued by that CA which are still active (not revoked and not expired), not just those issued in the time period for the report.

### 2.1.4.22 Report Manager

The Report Manager is used to run reports and manage existing reports, including scheduling delivery of reports. The Report Manager page shows all the available reports, not just those that have been configured to appear on the Management Portal top menu under Reports. Built-In Reports and Custom Reports are shown on separate tabs on the Report Manager page. Built-In reports have been organized into categories to allow you to filter the search results on the Report Manager grid by category of report.

With the Report Manager, custom Logi Analytics reports or custom reports from other external reporting solutions can be added into the portal to allow for easy running and scheduling. If you would like assistance creating a custom report in the new reporting engine, Logi Analytics, or displaying a custom report in the Report Manager, please contact your Client Success representative.

Tip: Be sure to check the filter on the category if you are not seeing all of the reports you expect to see. The default filter is All unless you have favorited some reports, in which case it is Favorite.

## Report Manager 9

Configure which reports are shown in the navigator, as well as which reports are able to be scheduled.

Figure 83: Report Manager Grid

**Tip:** If you **Save** a new certificate collection, or **Save** a change to an existing certificate collection, that change will be immediately reflected in the collection data used to display certificate collections on dashboards and reports. The data used by the dashboards and reports is stored in an intermediate table that is updated immediately. It will also continue to be updated periodically (approximately every 20 minutes by default as configured by the *Dashboard Collection Caching Interval* application setting) by the Keyfactor Command Service (see <u>Application Settings: Console Tab on page 603</u>).

## **Report Manager Operations**

From the Report Manager you can run reports on demand, edit reports (modify how a report displays, change the parameter definitions and add or change the schedule(s) used to run the report), or delete reports. From the top grid menu you can also quickly change the *Favorite* setting for a report.

## Run a Report

You can run a report on demand from the Report Manager page.

- 1. In the Management Portal, browse to Reports > Report Manager.
- 2. On the Report Manager page, highlight the report you wish to run in the grid and click **Run Report** from the top grid menu or the right click menu.
- 3. Populate the parameters as desired (see <u>Parameters Tab on page 130</u> for more information on parameters).
- 4. Click **Generate**. The report will display immediately in the open window. The report can be exported to Excel, PDF or CSV, as available for that report, via the **Export** button at the end of the report.

# **Editing a Report and Scheduling a Report for Delivery**

You can modify how a report displays, change the parameter definitions for running a report and add or change the schedule(s) used to deliver the report.

To edit an existing report:

- 1. In the Management Portal, browse to Reports > Report Manager.
- 2. On the Report Manager page, highlight the report you wish to modify in the grid and click **Edit** from the grid menu or the right click menu.
- 3. In the Report Manager dialog, edit the available options as needed.
- 4. Click **OK** to save the new or changed report details.

#### **Details Tab**

The most common edit to make on an existing report would be to check or uncheck the **Show in Navigator** box to add or remove the report from display on the Reports top menu, or to check or uncheck the **Favorites** box on the **Details** tab. The **Ignore Renewed Certificates** box will be available for reports that use collections to enable de-duplication (see the tip below). The **Uses Collection** box is for information only. It will be grayed out and checked for reports that use collections.

Figure 84: Edit a Report in Report Manager Details Tab

**Tip:** When de-duplication is enabled for a report, the report results will include only the most recently issued certificate if there is more than one certificate that matches the de-duplication criteria. De-duplication is enabled for a report by checking the *Ignore Renewed Certificates* box on the Details tab of the report configuration. De-duplication can only be enabled for reports that use certificate collections—the *Uses Collection* box on the Details tab. The *Uses Collection* setting is not user-configurable.

De-duping is configured on a certificate collection by setting the *Ignore renewed certificate* results by option when saving a certificate collection (see <u>Saving Search Criteria as a Collection on page 43</u>). Certificate collections may be configured to be de-duplicated based on the certificate common name, distinguished name, or principal name (or not at all). Only certificates that share all the EKUs (e.g. Client Authentication and Server Authentication) as well as the same CN, DN or UPN will be eliminated as duplicates. If a certificate has more than one EKU and at least one EKU does not match an otherwise similar certificate with matching CN, DN or UPN, it will not be eliminated.

For example, if the de-duplication logic was set to DN and the report would include these two certificates:

- Certificate one:
  - DN: CN=appssrvr14.keyexample.com,OU=IT,O=Key Example, Inc.,L=Chicago,ST=IL,C=US
  - EKUs: Server Authentication

- · Certificate two:
  - DN: CN=appssrvr14.keyexample.com,OU=IT,O=Key Example, Inc.,L=Chicago,ST=IL,C=US
  - EKUs: Server Authentication

• Issued Date: December 1, 2020

• Expiration Date: January 1, 2022

• Issued Date: December 15, 2020

Expiration Date: December 14, 2021

The de-duplication logic would be triggered because the DNs and EKUs match. The report would include certificate two and leave out certificate one. Notice that certificate two is retained even through certificate one expires after certificate two. This is because certificate two was issued after certificate one.

Now imagine that the de-duplication logic is set to CN and the report would include these two certificates:

• Certificate one:

DN:
 CN=appsrvr14.keyexample.com,OU=
 IT,O=Key Example, Inc.,L L=Chicago,ST=IL,C=US

EKUs: Server Authentication

Issued Date: December 1, 2020

Expiration Date: January 1, 2022

Certificate two:

DN:
 CN=appsrvr14.keyexample.com,OU=
 HR,O=Key Example, Inc.,L L=Chicago,ST=IL,C=US

 EKUs: Server Authentication, Client Authentication

• Issued Date: December 15, 2020

Expiration Date: December 14, 2021

Although the DNs for these certificates do not match, the CNs still do, so this matches the de-duplication logic of CN. However, the EKUs for these two certificates do not match, since only one of them includes Client Authentication. In this case, both certificates would appear on the report.

#### **Parameters Tab**

The Parameters tab will display all of the parameters for that specific report and allow you to configure default values to be used when the report is run from the Report Manager **Run Report** action button and what values default when adding a new schedule. You may also change the display name and description of the parameter.

To edit a parameter, select the **Parameters** tab, highlight the desired parameter in the parameters grid and click **Edit**, or double click the row. The *Parameters* dialog will open. Only those fields which can be edited will be enabled on the parameters details page. A change of the **Display Name** will change the name of parameter on the *Parameters* tab. A change of the **Description** will change the name of the description field on the *Schedule* tab. A change to the **Default Value** will define the value to use when the report is run from the Report Manager **Run Report** action button and what values default when adding a new schedule.

**Tip:** Some reports parameters use the **Add/Edit** button at the bottom of the dialog to open a Default Value dialog for to populate that parameter.

**Note**: The parameter fields will vary depending on the report selected. The parameters shown correspond to the specific parameters for each report. For more information on the parameters for a specific report, see the individual report under Reports on page 91.

Figure 85: Edit a Report in Report Manager Parameters Tab

Figure 86: Report Manager Parameters Tab: Parameter Details

# Schedule Tab

To add, edit, or delete a report delivery schedule, select the **Schedule** tab and choose the desired action. Any scheduled reports will appear on the schedule tab page. You can create multiple schedules with different parameters and recipients for the same report.

Figure 87: Edit a Report in Report Manager Schedule Tab

Figure 88: Edit a Report in Report Manager Schedule Tab - Add/Edit page

**Note**: Report scheduling is limited by collection permissions. Users in roles that have *Reports: Read and Modify* permissions will also need to have *Read* collection permissions on individual collections or global *Read* permissions for Certificates to have the ability to add, edit and delete schedules associated with collections. Any users without global *Read* permissions for Certificates will not have access to add, edit and delete schedules for any collections for which they do not have collection *Read* permissions in addition to *Reports* permissions.

### **Details section**

• **Schedule**: Choose the schedule by selecting Daily, Weekly or Monthly from the dropdown, then choosing the day or date, and the time to run the report.

Report Format: The available report formats are PDF, Excel and CSV\*.

**Note:** \*The CSV format is only available on reports that contain all the data within a single section (such as the Certificates in Collection report) rather than broken out into multiple sections (such as the Expiration Report).

Note: \*CSV format is not available for custom reports with multiple tables.

#### Dynamic Parameters:

Depending on the parameters specific to the report, you will use either a entry field, a dropdown or click the **Add/Edit** to open the selection window for the report parameters for the specific schedule you are working on.

- Some reports are based on a certificate collection, so one must be selected.
- Some reports allow you to set an evaluation date for the report other than the current date so that you can, for example, run an Expiration Report time shifted to 1 month in the future to see what the expiration picture will look like in a month's time or compare last year to this year.
- Some reports allow you to include custom metadata (see <u>Certificate Metadata on page 712</u>)
  in the report output.
- Some reports allow you to select specific templates or CAs for reporting.

### **Schedule Information Section**

• Save Report to File: You can choose to save your report to file by ticking the Save Report to File box, in which case you must provide a network path to which the file will be written in the Save Report Path (relative to the server) field. You will be given a warning message if the network path cannot be resolved. Although the record can still be saved with a path that doesn't resolve correctly, the report may fail to run if the path still does not resolve at the time the report runs.

**Note**: The path for saved reports must be provided in UNC format (\\server-name\\sharename\\path) and must be accessible from the Keyfactor Command administration server. In addition:

- Do not use a trailing "\" in the report path.
- Ensure that the service account for the Keyfactor Command Service has permission to write to the location where you want the outputted report to be saved.

- When scheduling a report, schedule it for at least 10 minutes in advance of the current time if you wish it to run soon. If you want to run it faster than that, the Keyfactor Command Service will need to be restarted.
- Send Report: You can choose to deliver your report via email by ticking the Send Report box, in
  which case you must provide at least one recipient in the Recipients field at the bottom of the
  dialog.

**Tip:** For an explanation of the parameters specific to each report, see the section in the documentation for that specific report under Reports on page 91.

Important: Scheduled reports will not run if the Keyfactor Command Service is stopped.

# **Deleting a Report**

To delete a report

- 1. In the Management Portal, browse to Reports > Report Manager.
- 2. On the Report Manager page, highlight the report you wish to delete in the grid and click **Delete** from the right-click menu.

**Note**: Only user-defined reports can be deleted. Built-in reports cannot be deleted. If you prefer not to see a built-in report, you may opt to remove the report from the menu by unchecking the **Show in Navigator** option.

### 2.1.5 Enrollment

The enrollment function in the Keyfactor Command Management Portal allows PKI administrators to request certificates by either submitting a certificate signing request (see <u>CSR Enrollment on the next page</u>) or by directly entering request information to receive a certificate delivered as a PFX file (see <u>PFX Enrollment on page 146</u>). The certificate file is available for immediate download via the browser or installation into a certificate store providing that the enrollment succeeds and the template used does not require manager approval. An option is also provided to generate a certificate signing request within Keyfactor Command. When you do this, the private key generated as part of the CSR generation process is stored—encrypted—in the Keyfactor Command database (see <u>CSR Generation on page 142</u>).

**Note**: As of Keyfactor Command version 10, enrollment (PFX and CSR), renewal, and revocation requests all flow through Keyfactor Command workflow. This will result in no changes to the enrollment, renewal, and revocation user experience unless customizations have been added in workflow (see *Workflow Definitions* in the *Keyfactor Command Reference Guide*).

See <u>Application Settings: Enrollment Tab</u> for configuration settings that apply to the enrollment functions in the Keyfactor Command Management Portal. Some enrollment functions are also affected by template settings. See <u>Configuring System-Wide Settings on page 383</u> and <u>Configuring Template</u> Options on page 388 for more information.

**Note**: The app pool service account must be set with permissions on the CA itself, in order to enroll via the CA in Keyfactor Command.

**Important:** Direct enrollment (without use of a Keyfactor CA gateway) is only supported for CAs in the forest in which Keyfactor Command is installed and any forests in a two-way trust with this forest. To do a cross-forest enrollment (with a forest in a two-way trust with the Keyfactor Command forest), Keyfactor Command requires that the root and intermediate CA certificates from the trusted forest are installed in the trusted root/intermediate stores in the Keyfactor Command server.

#### 2.1.5.1 CSR Enrollment

The certificate signing request (CSR) enrollment page provides the ability to submit a CSR and download the resulting certificate.

**Important:** Before you can use the CSR enrollment function, you must configure at least one template for enrollment by checking the **CSR Enrollment** box under **Allowed Enrollment Types** in the certificate template details. See Configuring Template Options on page 388.

**Note:** As of Keyfactor Command version 10, enrollment (PFX and CSR), renewal, and revocation requests all flow through Keyfactor Command workflow. This will result in no changes to the enrollment, renewal, and revocation user experience unless customizations have been added in workflow (see *Workflow Definitions* in the *Keyfactor Command Reference Guide*).

To request a certificate via CSR:

- 1. Generate a CSR. This can be done within the target application (e.g. Microsoft IIS), by using a tool such as certutil or OpenSSL, or by using the Keyfactor Command CSR generation tool (see CSR Generation on page 142).
- 2. In the Management Portal, browse to Enrollment > CSR Enrollment.
- 3. Paste your CSR into the **CSR Content** text area, with or without the BEGIN REQUEST/END REQUEST delimiters.

# CSR Enrollment 9

Paste the CSR below and enter any desired metadata to be associated with the issued certificate.

Figure 89: CSR Enrollment: CSR Content

4. The CSR contents will be parsed, and you will automatically be switched to the **CSR Names** view. Review the data to be sure it is as expected.

Figure 90: CSR Enrollment: CSR Names

**Note**: If a system-wide or template-level regular expression exists for a subject part or SAN, and the subject part or SAN is left blank, the regular expression will be applied to an empty string for that part. For example, if you have a regular expression on organization, but do not supply an organization, the regular expression will be applied to a blank string as if that were supplied as the organization.

5. If you are enrolling from an enterprise CA, select a certificate template from the **Template** drop-down. The templates are organized by configuration tenant (formerly known as forest). If you have multiple configuration tenants and templates with similar names, be sure to select the template in the correct configuration tenant.

Figure 91: Select a Certificate Template

Select the Certificate Authority from which the certificate should be requested. Only CAs that
have the selected template available for enrollment or are standalone, if you check the standalone CA box, will be shown.

- 7. The SAN section of the page appears if you enable the Allow CSR SAN Entry application setting (see <u>Application Settings: Enrollment Tab on page 610</u>). This option is disabled by default. In the Subject Alternative Names section of the page, click **Add** and select from the dropdown to enter one or more SANs for your CSR. Use the **Remove** action button to remove an existing SAN. The SAN field supports:
  - DNS name
  - IP version 4 address
  - · IP version 6 address
  - User Prinicpal Name
  - Email

Figure 93: CSR Enrollment SAN options

**Important:** If the RFC 2818 compliance setting is enabled for the selected template (see <u>Certificate Template Operations on page 382</u>), your request must have at least one SAN either included in the original CSR or entered separately in this field, which matches the CN in the request.

**Note**: Entering SANs here may either append or overwrite the SANs in the CSR request depending on how the issuing CA is configured. Please be sure to check that the certificate has the correct SANs after issuance. Any SAN added automatically as a result of RFC 2818 compliance settings at the policy handler level will still be added alongside anything you add here. For more information, review the SAN Attribute Policy Handler for the Keyfactor CA Policy Module (see *Installing the Keyfactor CA Policy Module Handlers* in the *Keyfactor Command Server Installation Guide*).

8. If template-specific enrollment fields have been defined (see <a href="Enrollment Fields Tab on page 391">Enrollment Fields Tab on page 391</a>) for the selected template, the fields will display in the Additional Enrollment Fields section. The types of fields shown could be either blank (string) fields or multiple choice drop-down fields depending on how they were configured on the template. All additional enrollment fields are mandatory.

Figure 94: Populate Enrollment Fields

9. In the Certificate Metadata section of the page, populate any defined certificate metadata fields (see <u>Certificate Metadata on page 712</u> and <u>Metadata Tab on page 394</u>) as appropriate for the template. These fields may be required or optional depending on your metadata configuration. Required fields will be marked with \*Required next to the field label. Any completed values will be associated with the certificate once it has been synchronized with Keyfactor Command. The order in which the metadata fields appear can be changed (see <u>Sorting Metadata Fields on page 717</u>).

Figure 95: Populate Metadata Fields

10. At the bottom of the page, select the radio button for the desired encoding format (PEM or DER).

Figure 96: Select a Certificate Format

- 11. Click the **Enroll** button to begin the certificate request process.
  - If the request completes successfully, you'll see a success message and you'll be prompted by your browser to begin download of your certificate.
  - If the template you selected requires approval at the Keyfactor Command workflow level, you'll see a message that your request is suspended and is awaiting one or more approvals. The user(s) responsible for approving the request will be notified (if the workflow has been configured this way, see <a href="Adding, Copying or Modifying a Workflow Definition on page 237">Adding, Copying or Modifying a Workflow Definition on page 237</a>). You can use the My Workflows Created by Me tab (see <a href="Workflows Created by Me tab">Workflows Created by Me tab</a> (see <a href="Workflows Created by Me tab">Workflows Created by Me tab</a> (see <a href="Workflows Created by Me tab">Workflows Created by Me tab</a> (see <a href="Workflows Created by Me tab">Workflows Created by Me tab</a> (see <a href="Workflows Created by Me tab">Workflows Created by Me tab</a> (see <a href="Workflows Created by Me tab">Workflows Created by Me tab</a> (see <a href="Workflows Created by Me tab">Workflows Created by Me tab</a> (see <a href="Workflows Created by Me tab">Workflows Created by Me tab</a> (see <a href="Workflows Created by Me tab">Workflows Created by Me tab</a> (see <a href="Workflows Created by Me tab">Workflows Created by Me tab</a> (see <a href="Workflows Created by Me tab">Workflows Created by Me tab</a> (see <a href="Workflows Created by Me tab">Workflows Created by Me tab</a> (see <a href="Workflows Created by Me tab">Workflows Created by Me tab</a> (see <a href="Workflows Created by Me tab">Workflows Created by Me tab</a> (see <a href="Workflows Created by Me tab">Workflows Created by Me tab</a> (see <a href="Workflows Created by Me tab">Workflows Created by Me tab</a> (see <a href="Workflows Created by Me tab">Workflows Created by Me tab</a> (see <a href="Workflows Created by Me tab">Workflows Created by Me tab</a> (see <a href="Workflows Created by Me tab">Workflows Created by Me tab</a> (see <a href="Workflows Created by Me tab">Workflows Created by Me tab</a> (see <a href="Workflows Created by Me tab">Workflows Creat

Figure 97: CSR Enrollment Completed Successfully—Awaiting Workflow Approval(s)

 If the template you selected requires manager approval at the CA level, you'll see a message that your request is pending. The user responsible for approving issuance of pending certificates will be notified (if that Management Portal feature is configured, see Pending Certificate Request Alerts on page 178). You can use the Certificate Requests page (see Certificate Requests on page 163) to check on the status of your pending request and complete the certificate download. If the Management Portal feature has been configured to send notification alerts when a pending certificate request is approved or denied, you may receive an email message when your certificate is available for download. The email message may contain a download link. See Issued Certificate Request Alerts on page 188 and Denied Certificate Request Alerts on page 197.

Figure 98: CSR Enrollment Completed Successfully—Pending Status

Tip: Click the help icon (2) next to the page title to open the embedded web copy of the Keyfactor Command Documentation Suite to this section.

You can also find the help icon at the top of the page next to the Log Out button. From here you can choose to open either the Keyfactor Command Documentation Suite at the home page or the Keyfactor API Endpoint Utility.

### 2.1.5.2 CSR Generation

The Certificate Signing Request (CSR) generation page provides the ability to enter a subject, SAN, key size, and template information and generate a CSR based on this information. You can then use this CSR to request a certificate using the CSR enrollment function (see CSR Enrollment on page 136) or any other enrollment method requiring a CSR.

When you use the CSR generation option, the encrypted private key of the request is stored in the Keyfactor Command database. When you generate a certificate using that CSR, it will be married together with the private key when the certificate synchronizes into the Keyfactor Command database. The certificate enrollment with the CSR does not need to be completed in Keyfactor Command (using CSR Enrollment) in order for the private key to be married with the certificate. Certificates enrolled outside of Keyfactor Command using CSRs generated within Keyfactor Command and synchronized via the CA synchronization process (see Certificate Authorities on page 350) or manually imported using the Add Certificate option (see Add Certificate on page 74) will also be married with their private keys.

#### To generate a CSR:

- 1. In the Keyfactor Command Management Portal, browse to Enrollment > CSR Generation.
- 2. In the Certificate Request Details section of the page:
  - a. Select a **Template**, if desired. The templates are organized by configuration tenant (formerly known as forest). If you have multiple configuration tenants and templates with similar names, be sure to select the template in the correct configuration tenant.

**Important**: The template will not be included in the CSR. The template is referenced in order to retrieve key and other information to help populate the CSR. In addition, the CSR generation function supports template-level regular expressions for both subject parts and SANs. If system-wide and template-level regular expressions exists for the same field and you select a template, the template-level regular expression is applied.

If you choose to select a template during CSR generation, you will need to choose the same template during CSR Enrollment, because the CSR file will contain elements from the template which may conflict with other template configurations.

b. Select a **Key Algorithm** and **Key Size** for your CSR. If you have selected a template, these dropdowns will be limited to the values supplied by the template. If the template supplies only one value for key algorithm and/or size, these dropdowns will be grayed out. When enrolling with the template, the key size of the request is validated against the template key size.

**Note**: The supported key algorithms for a certificate template are determined based on global template policy, individual template policy, and the template's supported algorithm.

When configuring template-level policies for key information, only key sizes that are valid for the algorithm will be available, according to the global template policy, the template policy, and the supported key sizes. For PFX and CSR generation, you will be offered the option to select the **Key Algorithm** and **Key Size** for the enrollment in dropdowns if the selected template with applied policy settings supports more than one of these. If, after applying Keyfactor Command policy to the returned template there is only one value for key algorithm and size, these dropdowns will be grayed

out. If for some reason an algorithm comes back as supported, but no key sizes are available, that algorithm should not appear. When selecting an ECC key size, the curve for that key size will be displayed.

Figure 99: CSR Generation

3. In the Certificate Subject Information section of the page, enter appropriate subject information for your CSR.

Note: Some subject fields may be automatically populated by system-wide or template-level enrollment defaults. You may override the system-populated data, if desired. Any system-wide or template-level regular expressions will be used to validate the data entered in the subject fields. System-wide or template-level policies will affect the request. For more information, see <a href="Certificate Template Operations on page 382">Certificate Template Operations on page 382</a>. Subject data may also be overridden after an enrollment request is submitted either as part of a workflow (see <a href="Update Certificate Request Subject\SANs">Update Certificate Request Subject\SANs</a> for <a href="Microsoft CAs">Microsoft CAs</a> on <a href="Dage 289">Dage 289</a>) or using the <a href="Subject Format">Subject Format</a> application setting (see <a href="Application Settings: Enrollment Tab on page 610).

4. In the Subject Alternative Names section of the page, click Add and select from the dropdown to enter one or more SANs for your CSR. Use the Remove action button to remove an existing SAN.

**Important:** If the template you selected has the RFC 2818 compliance setting enabled, the DNS name will be automatically populated with the Common Name (CN) and will be set to read only.

**Note**: If the CSR generated has multiple SANs, they will not be overridden by the template default settings, nor the RFC 2818 compliance settings.

The SAN field supports:

- DNS name
- · P version 4 address
- IP version 6 address
- User Prinicpal Name
- Email

Figure 100: CSR Generation SAN Options

5. At the bottom of the page, click the **Generate** button. You will see a success message. If any template-level or system-wide regexes have been applied to any fields on the CSR and failed you will receive a notice at the top of the CSR generation page indicating the error as defined on the template (whether template or system-wide settings prevail).

Figure 101: CSR Generation Success

6. Save or open your CSR once it has been successfully generated.

Tip: Click the help icon (3) next to the page title to open the embedded web copy of the Keyfactor Command Documentation Suite to this section.

You can also find the help icon at the top of the page next to the Log Out button. From here you can choose to open either the Keyfactor Command Documentation Suite at the home page or the Keyfactor API Endpoint Utility.

# 2.1.5.3 Pending CSRs

The Pending CSRs page allows you to see if you have any outstanding certificate signing requests that have been generated but not used for enrollment. From here, you can download them so that you can use them for enrollment or delete them if they are no longer needed. To download, highlight the selected row, right-click and choose **Download** from the right-click menu, or choose the **Down**load action button at the top of the grid.

### Pending CSRs 6

This is a list of all CSRs generated that have not yet been used to enroll for certificates.

DELETE DOWNLOAD	Total: 2 RE	FRESH
Request Time	CSR Subject	
6/21/2021, 10:57:12 AM	CN=appsrvr18.keyexample.com, E=info@keyexample.com, O=Keyexample, OU=Sales, L=Chicago, ST=IL, C=US, DNS Name=appsrvr18.keyexample.com, Key Length=2048, Key Type=RSA	
6/21/2021, 10:57:42 AM	CN=srvr18.keyexample.com, O=Keyexample, OU=IT, DNS Name=srvr18.keyexample.com, Key Length=2048, Key Type=RSA	

Figure 102: Pending CSRs

The pending certificate grid includes these fields:

- Request Time The date and time the CSR request was submitted in Keyfactor Command.
- Subject Name The subject name of the CSR, including key size, key type, and SANs, if applicable.

The CSRs can be sorted by clicking on the Request Time column header in the results grid. Click the column header again to reverse the sort order. The results grid columns can be arranged in any order desired by click-holding and dragging the header of the column you wish to move. The column widths may also be adjusted by click-holding and dragging the line separating two column headers.

### 2.1.5.4 PFX Enrollment

The PFX Enrollment page provides the ability to submit a certificate request and download the resulting PFX certificate file. Given the power involved in allowing a user to generate his or her own subject name and automatically receive a certificate in this subject name, Keyfactor recommends that permissions for this feature are only given to very trusted users and/or that you consider making use of Keyfactor Command workflow with a RequireApproval step (see Adding, Copying or Modifying a Workflow Definition on page 237).

**Important:** Before you can use the PFX enrollment function, you must configure at least one template for enrollment by checking the **PFX Enrollment** box under **Allowed Enrollment Types** in the certificate template details. In addition, if you wish to use a template that requires *CA certificate manager approval*, you must enable one of the **Private Key Retention** options in the certificate template details. See <u>Certificate Template Operations on page 382</u>.

**Note**: As of Keyfactor Command version 10, enrollment (PFX and CSR), renewal, and revocation requests all flow through Keyfactor Command workflow. This will result in no changes to the enrollment, renewal, and revocation user experience unless customizations have been added in workflow (see *Workflow Definitions* in the *Keyfactor Command Reference Guide*).

You can expand and collapse sections of the PFX enrollment page by clicking on the plus/minus icon to the left of each section title.

To request a certificate via PFX:

- 1. In the Keyfactor Command Management Portall, browse to Enrollment > PFX Enrollment.
- 2. If you are enrolling from an enterprise CA, select a certificate template from the **Template** drop-down. The templates are organized by configuration tenant (formerly known as forest). If you have multiple configuration tenants and templates with similar names, be sure to select the template in the correct configuration tenant. If you are enrolling from a standalone CA, check the **Use a stand-alone CA** box instead of selecting a template.

Figure 103: Select a Certificate Template

**Note**: The supported key algorithms for a certificate template are determined based on global template policy, individual template policy, and the template's supported algorithm.

When configuring template-level policies for key information, only key sizes that are valid for the algorithm will be available, according to the global template policy, the template policy, and the supported key sizes. For PFX and CSR generation, you will be offered the

option to select the **Key Algorithm** and **Key Size** for the enrollment in dropdowns if the selected template with applied policy settings supports more than one of these. If, after applying Keyfactor Command policy to the returned template there is only one value for key algorithm and size, these dropdowns will be grayed out. If for some reason an algorithm comes back as supported, but no key sizes are available, that algorithm should not appear. When selecting an ECC key size, the curve for that key size will be displayed.

3. Select the **Certificate Authority** from which the certificate should be requested. Only CAs that have the selected template available for enrollment or are standalone, if you check the standalone CA box, will be shown.

### PFX Enrollment 9 Complete the fields below and submit the form to enroll for a certificate and private key. Certificate Authority Information Template Kev Algorithm Key Size Enterprise Web Server 2048 Certificate Authority corpca01.keyexample.com\CorplssuingCA1 Certificate Subject Information Common Name Organization Organizational Unit appsrvr13.keyexample.com Key Example, Inc. City/Locality Country/Region State/Province Chicago US Illinois Fmail Custom Friendly Name Custom Friendly Name Subject Alternative Names ADD

appsrvr13.keyexample.com

Figure 106: PFX Enrollment

**DNS Name** 

**Note**: If a system-wide or template-level regular expression exists for a subject part or SAN, and the subject part or SAN is left blank, the regular expression will be applied to an empty string for that part. For example, if you have a regular expression on organization, but do not supply an organization, the regular expression will be applied to a blank string as if that were supplied as the organization

REMOVE

4. In the Certificate Subject Information section of the page, populate the fields as appropriate for the certificate being requested. Although Keyfactor Command does not strictly require the Common Name, the product does ship with a default regular expression requiring a value for this field since it is typical for a CA to require this unless the template is set to populate the subject from Active Directory. This regular expression may have been altered in your environment (see the below note).

**Note:** Some subject fields may be automatically populated by system-wide or template-level enrollment defaults. You may override the system-populated data, if desired. Any system-wide or template-level regular expressions will be used to validate the data entered in the subject fields. System-wide or template-level policies will affect the request. For more information, see Certificate Template Operations on page 382.

Subject data may also be overridden after an enrollment request is submitted either as part of a workflow (see <u>Update Certificate Request Subject\SANs for Microsoft CAs on page 289</u>) or using the *Subject Format* application setting (see <u>Application Settings:</u> <u>Enrollment Tab on page 610</u>).

- 5. If enabled, add a friendly name in the Custom Friendly Name section of the page. This section only appears if the Allow Custom Friendly Name application setting is set to True. If the Require Custom Friendly Name application is set to True, a value is required in this field. For more information, see Application Settings: Enrollment Tab on page 610.
- 6. In the Subject Alternative Names (SANs) section of the page, add SANs if needed. If the RFC 2818 compliance option has been enabled for the template (see <u>Certificate Template Operations on page 382</u>), the first SAN field will automatically populate with a DNS SAN matching the CN when you enter the CN be set to *Read Only*. Click the **Add** button to add SAN fields.

**Important:** If the template you selected has the RFC 2818 compliance setting enabled, the DNS name will be automatically populated with the Common Name (CN) and will be set to read only.

### The SAN field supports:

- DNS name
- IP version 4 address
- · IP version 6 address
- User Prinicpal Name
- Email

Figure 107: PFX Enrollment: SAN Options

This field is not required unless the RFC 2818 compliance option has been configured in the template policy.

7. If template-specific enrollment fields have been defined (see <u>Enrollment Fields Tab on page 391</u>) for the selected template, the fields will display in the Additional Enrollment Fields section. Additional enrollment fields have a data type of either string or multiple choice. String fields will appear as a text box; Multiple choice fields will appear as a dropdown. All additional enrollment fields are required.

Figure 108: Populate Enrollment Fields

8. In the Certificate Metadata section of the page, populate any defined certificate metadata fields (see <u>Certificate Metadata on page 712</u> and <u>Certificate Template Operations on page 382</u>) as appropriate for the template. These fields may be required or optional depending on your metadata configuration. Required fields will be marked with \*Required next to the field label. Any completed values will be associated with the certificate once it has been imported into Keyfactor Command. The order in which the metadata fields appear can be changed (see <u>Sorting Metadata Fields on page 717</u>).

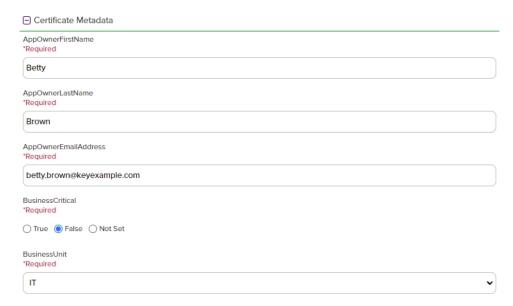

Figure 109: Populate Metadata Fields

9. If enabled, in the Password section of the page, check the Use Custom Password box and enter and confirm a custom password to use in securing the PFX file. This section only appears if the Allow Custom Password application setting is set to True. The value in the Password Length field in application settings is shown for guidance when entering a password. For more information about both of these settings, see Application Settings: Enrollment Tab on page 610.

Figure 110: Set a Custom Password

10. In the Certificate Delivery Format section of the page, select either **Direct Download**—to download the certificate immediately—or **Install into Certificate Stores**—to schedule the certificate to be added to a configured certificate store. If you do not have any configured certificate stores, the Install into Certificate Stores option will not appear.

### **Direct Download**

If you selected Direct Download, choose whether to include the certificate chain with the returned certificate by toggling **Include Chain**. If you toggle Include Chain to on, choose a **Chain Order** and specify either **End Entity First** or **Root First** order. The option to specify the order will only be available if the selected format supports it, otherwise the order will always be **End Entity First**.

The **Use Legacy Encryption** option applies only to certificates downloaded in PFX format. If this option is toggled to **On**, the PFX file is encrypted using the historical algorithm (3DES/SHA1/RC2). If this option is toggled to **Off**, the newer algorithm set provided by Windows (AES256/SHA256/AES256) is used instead. The default for the PFX enrollment page can be set with the *Use Legacy Encryption* application setting (see <u>Application Settings: Enrollment Tab on page 610</u>). The toggle defaults to off.

The supported **Formats** for output are:

- PFX (PKCS#12)
- PEM (one PEM file, with optional chain)
- ZIP PEM (A ZIP file with individual PEM files for certificate, private key, and each part of the chain, if included)
- JKS

Figure 111: Delivery Format PFX Enrollment

### **Install into Certificate Stores**

If you have any certificate stores defined, you may opt to install the certificate directly into one or more certificate stores on enrollment. If you choose to do this, the certificate will not be available for download on this page.

To install a certificate into a certificate store, select the **Install into Certificate Stores** radio button and then click the **Include Certificate Stores** button. This will cause the *Select Certificate Store Locations* dialog to appear. Make your certificate store selections in this dialog as described in *Select Certificate Store Locations*, below, and click **Include and Close**. You will then see some additional fields on the enrollment page. Populate these as per *Add to Certificate Stores* and *Information Required for Certificate Stores*, below.

### **Select Certificate Store Locations**

The Select Certificate Store Locations dialog allows you to run queries against your certificate store list to select which store(s) to deploy a selected certificate to. **Check** the box next to each certificate store location to which you want to distribute the certificate.

**Note:** Only compatible certificate stores and only stores in containers to which you have permissions are shown on the grid.

**Tip:** You may change the search results by using the search fields at the top of the dialog. All of the Keyfactor Command grid search features are available to assist your search. See <a href="Using the Certificate Store Search Feature">Using the Certificate Store Search Feature on page 411</a> for more information on the available search fields. The default search criteria is *AgentAvailable is equal to True*.

The actions on the Select Certificate Store Locations dialog are:

Include

Click this to add the selected certificate store(s) to your certificate selection and leave the search dialog open for further searches.

• Include and Close

Click this to close the search dialog and add the selected certificate store(s) to your certificate selection, which will then be displayed and ready for updates as per the instructions in *Add to Certificate Stores*.

#### Close

Click this to cancel the operation and return to the main page with no certificate stores selected.

Figure 112: Select Certificate Store Locations Dialog

### **Add to Certificate Stores**

The additional fields that appear on the page once you select at least one certificate store to distribute your certificate to include a grid section with a series of tabs that displays a tab for each type of certificate store selected with a list of the selected stores under each tab.

Above this section are global options that apply to the add job as a whole:

· Schedule when to run the job for the certificate store

In the **Schedule** dropdown, select a time at which the job to add the certificate to the stores should run. The choices are *Immediate* or *Exactly Once* at a specified date and time. If you

choose *Exactly Once*, enter the date and time for the job. A job scheduled for *Immediate* running will run within a few minutes of saving the operation. The default is *Immediate*.

#### Include Certificate Stores

Open the Select Certificate Store Locations dialog again.

For each selected certificate store you can apply the following actions:

### Overwrite

Check **Overwrite** below the grid to allow the selected certificate to overwrite any existing certificate in the same location with the same name or alias.

#### Alias

Add an **Alias** below the grid, if applicable, for the certificate store type. See the **Information Required by Certificate Store** section, below, for more information.

**Note:** The tab heading of the certificate location will display an alert if an alias is required for the location.

#### Remove

Click **Remove** at the top of the grid to remove the selected certificate store from the page. The certificate will not be added to the store.

You may return to the *Select Certificate Store Locations* dialog by clicking **Include Certificate Stores** above the grid. The current selections will be retained.

Figure 113: PFX Enrollment: Certificate Delivery Format

# Information Required by Certificate Stores

Each type of certificate store has different requirements for providing an alias or other additional information.

The certificate store type fields that are relevant to certificate store use are:

### Supports Entry Password

If your certificate store type has this enabled, you will have the option to enter a password for the certificate entry in the certificate store on the addition of an entry into the certificate store.

Figure 114: Certificate Store Type Configuration: Basic Tab

# Supports Custom Alias

A value of *Required* indicates that a custom alias will be required when a certificate is added to a certificate store. *Optional* indicates an alias can be associated with the entry if desired. If your certificate store type sets this to *Forbidden*, the *Alias* field will not display when adding a certificate to a certificate store unless *Overwrite* is checked on the add page. In this case, you're not associating an alias with the certificate you're adding to the store but rather specifying the alias of the certificate already in the store that you wish to replace (in function) with the new certificate you're adding.

The format of custom alias values varies depending on the certificate store type. In many cases, the alias is the thumbprint of the certificate. In some cases, it's the file name of the certificate file or a custom alias provided at the time the certificate was added to the certificate store. For instance:

 For an Amazon Web Services (AWS) store, the alias is the internal ID assigned by Amazon (the Amazon resource number or ARN). Provide the entire contents of the Alias/IP from this field when entering an alias for overwrite. For example:

arn:aws:acm:us-west-2:220531701668:certificate/88e5dcfb-a70b-4636-a8ab-e85e8ad88780

o For F5 stores using the Keyfactor custom-built F5 Certificate Store Manager extension (see Installing Custom-Built Extensions in the Keyfactor Orchestrators Installation and Configuration Guide), the alias is the file name used to store the file in the device file system, minus the extension (e.g. use alias MyFile for a file named MyFile.crt). Aliases should be entered without spaces. Note that certificate names are case sensitive.

**Note**: Keyfactor Command will automatically strip out any spaces between the octets in thumbprints in the alias field, so it does not matter whether you enter the thumbprint with or without spaces.

**Tip:** When adding a certificate to a certificate store, you have the option to overwrite an existing certificate with the current certificate. If you choose this option, you will need to provide the alias of the certificate you wish to overwrite. Find the alias values by navigating to *Management Portal > Certificates > Certificate Search*. Select the certificate you wish to overwrite and double-click, or click **Edit**, from the grid header or right-click menu. Choose the **Locations** tab and double-click on the Location Type (this must have a number other than zero in the *Count* column) to open the details dialog. The *Alias* field holds the information that may be required for an overwrite.

# • Private Key Handling

When adding a certificate to a certificate store, if you select a certificate that does not have an associated private key, certificate stores with this option set to *Required* will not appear as available stores to which the certificate can be added. If this option is set to *Forbidden* and the selected certificate has a private key, the private key will be ignored and only the public key will be delivered to the target.

Note: Private keys are always available in PFX Enrollment.

Figure 116: Certificate Store Type Configuration: Advanced Tab

# Entry Parameters

Not all certificate store types will have entry parameters. The ones shown in Figure 117: Certificate Store Type Configuration: Entry Parameters Tab are for the custom Windows Certificate type for the Keyfactor custom-built IIS Certificate Store Manager extension (see Installing Custom-Built Extensions in the Keyfactor Orchestrators Installation and Configuration Guide).

Figure 117: Certificate Store Type Configuration: Entry Parameters Tab

- 11. At the bottom of the page, click **Enroll** to begin the certificate request process.
  - If the request completes successfully, you'll see a success message. When the certificate
    is enrolled and issued the message will state the download format type, if the private key
    was included in the downloaded certificate, if the certificate chain was included in the
    downloaded certificate. If private key was not retained for the downloaded certificate, no
    password will be displayed a message will state that the private key and certificate can be
    obtained from the certificate search page.
  - You'll be prompted by your browser to begin download of your certificate unless you chose
    to install it directly into a certificate store. If you've configured PFX enrollment to use
    Windows authentication (the default) and have not selected the option to enter a custom
    password, you'll see a one-time password that has been generated to secure the PFX file.
    You will need this password in order to open the PFX file.
  - If you've configured the Keyfactor Command Management Portal to use basic authentication and you've configured the *Use Active Directory Password* application setting option to True, the message will indicate that the PFX file can be opened using the Active Directory domain password of the user making the request. For more information about configuring basic authentication versus Windows authentication, see Application Settings:

### Enrollment Tab on page 610.

# PFX Enrollment 9

Certificate Issued Successfully

The PFX certificate has been issued successfully, and delivered.

Your network password has been used to protect the private key.

Figure 118: PFX Enrollment Completed Successfully—Network Password Used

**Note**: This option does not work when you authenticate to the Management Portal using Kerberos because Keyfactor Command does not have access to your credentials to apply your password to the PFX file.

• If the template you selected requires approval at the Keyfactor Command workflow level, you'll see a message that your request is suspended and is awaiting one or more approvals. The user(s) responsible for approving the request will be notified (if the workflow has been configured this way, see <a href="Adding, Copying or Modifying a Workflow Definition on page 237">Adding, Copying or Modifying a Workflow Definition on page 237</a>). You can use the My Workflows <a href="Created by Me">Created by Me</a> tab (see <a href="Workflows Created by Me">Workflows Created by Me</a> tab (see <a href="Workflows Created by Me">Workflows Created by Me</a> tab (see <a href="Workflows Created by Me">Workflows Created by Me</a> tab (see <a href="Workflows Created by Me">Workflows Created by Me</a> tab (see <a href="Workflows Created by Me">Workflows Created by Me</a> tab (see <a href="Workflows Created by Me">Workflows Created by Me</a> tab (see <a href="Workflows Created by Me">Workflows Created by Me</a> tab (see <a href="Workflows Created by Me">Workflows Created by Me</a> tab (see <a href="Workflows Created by Me">Workflows Created by Me</a> tab (see <a href="Workflows Created by Me">Workflows Created by Me</a> tab (see <a href="Workflows Created by Me">Workflows Created by Me</a> tab (see <a href="Workflows Created by Me">Workflows Created by Me</a> tab (see <a href="Workflows Created by Me">Workflows Created by Me</a> tab (see <a href="Workflows Created by Me">Workflows Created by Me</a> tab (see <a href="Workflows Created by Me">Workflows Created by Me</a> tab (see <a href="Workflows Created by Me">Workflows Created by Me</a> tab (see <a href="Workflows Created by Me">Workflows Created by Me</a> tab (see <a href="Workflows Created by Me">Workflows Created by Me</a> tab (see <a href="Workflows Created by Me">Workflows Created by Me</a> tab (see <a href="Workflows Created by Me">Workflows Created by Me</a> tab (see <a href="Workflows Created by Me">Workflows Created by Me</a> tab (see <a href="Workflows Created by Me">

# PFX Enrollment 9

Enrollment In Process

Awaiting 1 more approval(s) from approval roles.

Figure 119: PFX Enrollment Completed Successfully—Awaiting Workflow Approval(s)

• If the template you selected requires manager approval at the CA level, you'll see a message that your request is pending. The user responsible for approving issuance of pending certificates will be notified (if that Management Portal feature is configured, see Pending Certificate Request Alerts on page 178). You can visit the Certificate Requests page (see Certificate Requests on the next page) to check on the status of your pending request and certificate search (see Certificate Search and Collections on page 20) to complete the certificate download. If the Management Portal feature has been configured to send notification alerts when a pending certificate request is approved or denied, you may receive an email message when your certificate is available for download. The email message may contain a download link. See Issued Certificate Request Alerts on page 188 and Denied Certificate Request Alerts on page 197.

### PFX Enrollment 9

Certificate Requires Approval

The certificate requires authorization. The certificate and private key will be available for download via the Certificate Search page once it has heen approved and Issued

Figure 120: PFX Enrollment Completed Successfully—Pending Status

Tip: Click the help icon (3) next to the page title to open the embedded web copy of the Keyfactor Command Documentation Suite to this section.

You can also find the help icon at the top of the page next to the Log Out button. From here you can choose to open either the Keyfactor Command Documentation Suite at the home page or the Keyfactor API Endpoint Utility.

### 2.1.5.5 Certificate Requests

The Certificate Requests page shows certificate requests made to certificate authorities that have been configured to synchronize to the Keyfactor Command database and which have a status of pending, external validation or denied/failed. You can approve or deny pending certificates from this page (see Approving or Denying a Pending Certificate Request on page 165).

Tip: Click the help icon (2) next to the page title to open the embedded web copy of the Keyfactor Command Documentation Suite to this section.

You can also find the help icon at the top of the page next to the Log Out button. From here you can choose to open either the Keyfactor Command Documentation Suite at the home page or the Keyfactor API Endpoint Utility.

### **Viewing Certificate Requests**

The Certificate Requests grid has three tabs: Pending, External Validation and Denied/Failed. Select the appropriate tab to the view desired certificate requests. You may also filter the list shown by entering all or part of a Requester Name and clicking Filter to change which requests are displayed.

Note: Certificate requests that require approval at the Keyfactor Command workflow level (see Workflow Definitions on page 230) do not appear on this page.

### Pending

Typically a request in this state has been made using a template that requires manager approval at the CA level before issuance. The request may be approved or denied from this tab of the certificate requests page or though action on a Pending Request Alert (see Pending Certificate Request Alerts on page 178). When the pending requests tab is selected, you will see Approve and Deny buttons activated at the top of the grid. By clicking Details, you can view the

certificate details and **Approve** or **Deny** the request from the Certificate Request Details dialog. See Approving or Denying a Pending Certificate Request on the next page for more information.

#### External Validation

Certificate requests in this state require approval outside of Keyfactor Command. Certificates appearing on this tab generally are for requests made through one of the Keyfactor Command CA gateways using an EV certificate type. The requests appear here for reference only and cannot be approved or denied. Once a request has been approved using the cloud provider's EV approval process, the Keyfactor Command CA gateway and Keyfactor Command will import the issued certificate on the next synchronization. The synced certificate will move to the Certificate Search grid (see Certificate Search and Collections on page 20) and can be viewed there.

### Denied/Failed

The denied/failed view shows requests that have been denied through Keyfactor Command as an action on the certificate requests page **Pending** tab though action on a *Pending Request Alert* (see <u>Pending Certificate Request Alerts on page 178</u>), or through a *POST /Workflow/Certificates/Deny* API request (see *POST Workflow Certificates Deny* in the *Keyfactor API Reference Guide*), but does not include requests denied directly from the CA outside of Keyfactor Command.

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Monitoring > Alerts > Read

The certificate requests grid includes these fields:

### **Keyfactor Request ID**

The reference ID of the request from the Keyfactor database.

### **Common Name**

The requested common name of the request.

### **Distinguished Name**

The requested distinguished name of the request.

### Submission Date

The date on which the request was submitted.

#### **Certificate Authority**

The CA against which the request was made.

#### **Template**

The short name of the template used to make the request.

#### Requester

The user or entity that made the request.

### State

The request status—failed, pending or external validation as per the tab selected.

By default, the grid sorts in descending order with the most recent certs at the top. The grid can be sorted in ascending or descending Submission Date order by clicking on the column header. he grid columns can be arranged in any order desired by click-holding and dragging the header of the column you wish to move. The column widths may also be adjusted by click-holding and dragging the line separating two column headers.

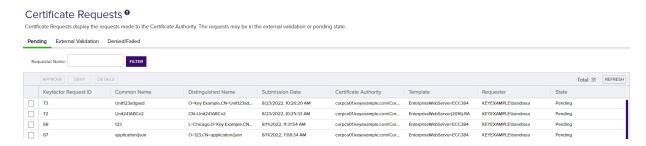

Figure 121: Certificate Requests Grid

The **Details** button appears activated for all views. The details page includes the SANs, metadata, and certificate stores scheduled for distribution for the request, in addition to the information shown on the main grid.

Figure 122: Certificate Request Details

# Approving or Denying a Pending Certificate Request

On the **Pending** tab of the certificates requests grid you can view the **Details** of a certificate request that required manager approval at the CA level and choose to **Approve** or **Deny** it by clicking the action buttons at the top of the grid. You can also **Approve** or **Deny** the request from the Certificate Request Details dialog. The approve and deny operations can be done on multiple requests at once. To select multiple rows, click the checkbox for each row on which you would like to perform an oper-

ation, then select an operation from the top of the grid. The right-click menu only supports operations on one request at a time.

- When you deny a request, you will be prompted to enter a comment regarding the denial. These
  comments can be delivered to the requester or other interested party using a denied request
  alert (see <u>Denied Certificate Request Alerts on page 197</u>). When a certificate is denied, its
  status will change to failed and it will move from the pending grid tab to the denied/failed grid
  tab. The denial comments will display in the Certificate Request Details dialogue.
- When a request is approved on this page, the certificate will move to the Certificate Search grid
  (see <u>Certificate Search and Collections on page 20</u>) and can be viewed there. If you have
  configured issued certificate alerts (see <u>Issued Certificate Request Alerts on page 188</u>), the
  requester or other interested party will be notified immediately on approval.

**Note:** Certificate requests that require approval at the Keyfactor Command workflow level (see <u>Workflow Definitions on page 230</u>) do not appear on this page.

**Tip**: The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Monitoring > Alerts > Read Certificates > Requests Manage

Certificate requests with a pending status have generally either been requested using certificate templates requiring manager approval at the CA level or from a CA configured to send all requests to pending automatically.

Figure 123: Certificate Template Requiring Manager Approval

**Note**: Certificate requests that require approval at the CA level are supported only for Microsort CAs and select CA gateways. This feature is not supported for EJBCA CAs. Use workflow for configuring Keyfactor Command-level approvals for EJBCA CAs (see <a href="Workflow">Workflow</a> Definitions on page 230).

# 2.1.6 Alerts

The options available in the Alerts section of the Management Portal are:

- · Expiration Alerts below
  - Create email notifications that alert administrators and/or end users when certificates are coming up for expiration.
- Pending Certificate Request Alerts on page 178

Create email notifications that alert PKI administrators when a new pending certificate request is made.

- Issued Certificate Request Alerts on page 188
  - Create email notifications that alert a certificate requester when a certificate he or she requested has been issued.
- Denied Certificate Request Alerts on page 197

Create email notifications that alert a certificate requester when a certificate he or she requested has been denied.

- Key Rotation Alerts on page 203
  - Create email notifications that alert end users and PKI administrators when an SSH key is nearing the end of its lifetime.
- Revocation Monitoring on page 210

Define locations where certificate revocation lists (CRLs) and online certificate status protocol (OCSP) locations may be found and enable expiration notification alerts for them.

#### 2.1.6.1 Expiration Alerts

Expiration alerts are used to send email notifications to certificate owners, users and/or administrators when a certificate is nearing or at expiration. The alerts can be customized to provide detailed information about the certificates along with, for example, instructions to end users on how to enroll for a replacement certificate.

#### **Expiration Alert Operations**

Expiration alerts are based on certificate collections. Before you can work with expiration alerts, you need to have created a certificate collection on which to base the alert (see <a href="Certificate Search">Certificate Search</a> and Collections on page 20).

# Adding or Modifying an Expiration Alert

- 1. In the Management Portal, browse to *Alerts > Expiration*.
- 2. On the Expiration Alerts page, click **Add** from the top menu to create a new alert, or **Edit** from either the top or right click menu, to modify an existing one.
- 3. In the Certificate Expiration Alert Settings dialog, select your **Certificate Collection** in the first dropdown.

Figure 124: Create a New Expiration Alert

4. In the **Timeframe** fields, select the warning timeframe by defining a number for either days, weeks, or months for the alert. For example, if you select three weeks, the expiration alerts will be sent automatically three weeks ahead of certificate expiration.

**Note**: When the alert is stored in the database, weeks are converted to 7 days and months are converted to 30 days.

**Example:** When alerts run, the alert engine reports on all the certificates expiring within the next X days (e.g. 30 days) from the execution time that have not previously been reported on. This means that if the alerts run daily and have been running daily regularly

for some time, only a single day of expiring certificates will be reported on by any given alert run.

For example, say you create a new alert that has never run before for collection A and set it to 30 days. You configure it to run daily at 5:00 am. The alert runs for the first time at 5:00 am on July 1st. All the certificates in collection A that will expire between July 1st at 12:00 am UTC and July 31 at 12:00 am UTC will be alerted on. The next day when the alert runs again at 5:00 am on July 2nd, the certificates in collection A expiring between July 31st at 12:00 am UTC and August 1st at 12:00 am UTC will be alerted on.

If alerts are missed for a period of time (due to an outage, for example), the next run of the alerts will check the previous successful run date for the alerts and report on certificates expiring X days from that outage window. For example, using the collection A alert referenced above, say an outage caused the alerts not to run on August 1 and August 2. On August 3, the alert would run again at 5:00 am, and the certificates in collection A expiring between August 30th at 12:00 am UTC and September 2nd at 12:00 am UTC would be alerted on.

- 5. In the Display Name field, enter a name for the alert. This name appears in the list of expiration alerts in the Management Portal.
- 6. In the **Subject** field, enter a subject line for the email message that will be delivered when the alert is triggered. You can use substitutable special text in the subject line. Substitutable special text uses a variable in the alert definition that is replaced by data from the certificate or certificate metadata at processing time. For example, you can enter {cn} in the alert definition and each alert generated at processing time will contain the specific common name of the given certificate instead of the variable {cn}.

To add substitutable special text to the subject line; place your cursor where you would like the text to appear on the subject line, select the appropriate variable from the Insert special text dropdown, and click Insert. Alternately, type the special text variable enclosed in curly braces (e.g. {cn}).

7. In the **Message** box, enter the body of the email message that will be delivered when the alert is triggered. You can use the Insert special text dropdown below the message window to add substitutable special text to the message. The metadata that appears in the dropdown will depend upon the custom metadata you have defined (see Certificate Metadata on page 712). Place your cursor where you would like the text to appear, select the appropriate variable from the dropdown, and click Insert. Alternately, you can type the special text variable enclosed in curly braces directly. In addition to the substitutable special text fields available in the dropdown, you can also build your own substitutable fields for the principal and/or requester based on string values from the user or computer Active Directory record. See Table 4: Substitutable Special Text for Expiration Alerts. If desired, you can format the message body using HTML. For example, you could place certificate detail information into a table by replacing this text:

DN: {dn} CN: {cn} UPN: {upn}
Thumbprint: {thumbprint}
Serial Number: {serial}

#### With this HTML code:

```
DN:{dn}
DN:{dn}
CN:{cn}
UPN:{upn}
Thumbprint:{thumbprint}
Serial Number:{serial}
```

- 8. Check the **Use handler** box if you would like the alert to trigger an event handler at processing time, select the appropriate handler in the dropdown, and click the **Configure** button to configure the event handler. See <a href="Event Handler Registration on page 741">Event Handler Registration on page 741</a> for more information on using event handlers, and <a href="Adding PowerShell Handlers to Alerts on page 223">Adding PowerShell Handlers</a>.
- 9. In the Recipients section of the page, click Add to add a recipient to the alert. Each alert can have multiple recipients. Recipients should be added one at a time. You can enter specific email addresses and/or use substitutable special text to replace an email address variable with actual email addresses at processing time. The built-in variable can be selected in the Recipient dialog Use a variable from the certificate dropdown. In addition, you can type a special text variable enclosed in curly braces in the Email field if you have, for example, a metadata field that contains an email address.

Keyfactor Command sends SMS (text) messages by leveraging the email to text gateways that many major mobile carriers provide. Check with your carrier for specific instructions. Keyfactor has tested that AT&T can be addressed using 10-digit-number@txt.att.net (e.g. 4155551212@txt.att.net) and Verizon can be addressed using 10-digit-number@vtext.com (e.g. 2125551212@v-text.com). T-Mobile can be addressed using 10-digit-number@tmomail.net (e.g. 2065551212@tmomail.net), but functionality can be spotty. Reliability of alerting via this method depends on the reliability of the carrier's gateways.

Figure 125: Expiration Alerts Recipients

10. Click Save to save your expiration alert, or your changes.

# Copying an Expiration Alert

You may use the copy operation to create multiple similar alerts—for example, several alerts for the same certificate collection but with different warning timeframes.

- 1. In the Management Portal, browse to *Alerts > Expiration*.
- 2. On the Expiration Alerts page, highlight the row in the expiration alerts grid and click **Copy** at the top of the grid, or from the right click menu.
- 3. The Certificate Expiration Alert Settings dialog will pop-up with the details from the selected alert. The display name field will have *Copy* tagged to the end of it to indicate it is a new alert. You may modify the alert as needed and click **Save** to add the new alert, or **Cancel** to cancel the operation.

#### **Deleting an Expiration Alert**

You may delete one expiration alert at a time.

- 1. In the Management Portal, browse to *Alerts > Expiration*.
- 2. On the Expiration Alerts page, highlight the row in the Expiration Alerts grid and click **Delete** at the top of the grid, or from the right click menu.
- 3. On the Confirm Operation alert, click **OK** to confirm or **Cancel** to cancel the operation.

#### Configuring an Expiration Alert Schedule

After adding your desired Certificate Expiration Alerts, you may configure an alert schedule.

- 1. In the Management Portal, browse to *Alerts > Expiration*.
- 2. On the Expiration Alerts page, click the **Configure** button at the top of the Expiration Alerts page to configure a monitoring execution schedule. This will apply for all the expiration alerts.

This defines the frequency with which alerts are sent. This type of alert is scheduled for daily delivery at a specified time.

**Example:** When alerts run, the alert engine reports on all the certificates expiring within the next X days (e.g. 30 days) from the execution time that have not previously been reported on. This means that if the alerts run daily and have been running daily regularly for some time, only a single day of expiring certificates will be reported on by any given alert run. For example, say you create a new alert that has never run before for collection A and set it to 30 days. You configure it to run daily at 5:00 am. The alert runs for the first time at 5:00 am on July 1st. All the certificates in collection A that will expire between July 1st at 12:00 am UTC and July 31 at 12:00 am UTC will be alerted on. The next day when the alert runs again at 5:00 am on July 2nd, the certificates in collection A expiring between July 31st at 12:00 am UTC and August 1st at 12:00 am UTC will be alerted on.

If alerts are missed for a period of time (due to an outage, for example), the next run of the alerts will check the previous successful run date for the alerts and report on certificates expiring X days from that outage window. For example, using the collection A alert referenced above, say an outage caused the alerts not to run on August 1 and August 2. On August 3, the alert would run again at 5:00 am, and the certificates in collection A expiring between August 30th at 12:00 am UTC and September 2nd at 12:00 am UTC would be alerted on.

Figure 126: Expiration Alert Schedule

#### **Testing Expiration Alerts**

Once the alerts are configured, you may run a test of all, or selected, alerts to see if they are configured correctly.

- 1. In the Management Portal, browse to *Alerts > Expiration*.
- On the Expiration Alerts page, either highlight one row in the expiration alert grid and click the Test button at the top of the grid or click the Test All button at the top of the grid to test all the alerts.
- 3. In the Expiration Alert Test dialog in the Alert Parameters section, select a **Start Date** and **End Date** for testing. You can use this option to simulate running the alerts a month from now instead of today, for example, or put in a broad date range to be sure you pick up some expiring certificates for testing purposes.

Example: Say you had experienced an outage and alerts that normally run daily at 5:00 pm did not run for two days. You wanted to test to see what to expect of the alerts once the system was up and running again. You are running your test on August 3rd for an alert that's configured to report at 30 days for collection A. The alert last ran on July 31. This means the alert has a *Previous Evaluation Date* of July 31. When running your test, set the Start Date to July 31st to match the Previous Evaluation Date. Set the End Date to the current date, August 2nd in this example, to simulate the results when the alerts are run today. The test results will include up to 100 certificates in collection A expiring between August 30th at 12:00 am UTC and September 1st at 12:00 am UTC.

- 4. In the Expiration Alert Test dialog in the Alert Parameters section, click the toggle button for Send Alerts if you would like to deliver email messages as part of the test.
- 5. Click the Generate button to begin generating alerts. Depending on the number of certificates to process, this may take a few seconds.
- 6. In the Expiration Alert Test dialog in the Alert Data and Alert Message sections, you can review the certificates found to confirm that the expected certificates are appearing and that the substitutable special text is being replaced as expected. Scroll through the alerts using the First, Previous, Next and Last buttons at the bottom of the dialog. The number of alerts generated will display between the navigation buttons.

Note: You may see fewer alerts than you have certificates expiring in the selected time window for the certificate collection if you enabled one of the options to ignore duplicate certificates on the certificate collection (see Saving Search Criteria as a Collection on page 43).

Tip: Alerts are generated when a certificate has expired or is approaching expiration as defined by the timeframe configured in the alert.

By default, a maximum of 100 alerts will be generated during a test. The maximum value is configurable with the Expiration Alert Test Result Limit setting in Keyfactor Command application settings (see Application Settings: Console Tab on page 603 in the Keyfactor Command Reference Guide). If more than 100 alerts are generated, no email messages will be sent and you'll have the opportunity to view the first 100 alerts generated.

If you're using an event handler, the event handler is run and the handler actions taken (PowerShell script run, event log message written, certificates renewed) when the test is run. This is true whether or not you click the Send Alerts toggle.

Note: HTML does not render in the alert viewer.

Figure 127: Expiration Alert Test

Refer to the following table for a complete list of the substitutable special text that can be used to customize alert messages.

Table 4: Substitutable Special Text for Expiration Alerts

Variable	Name	Description
{certemail}	Email Address in Certificate	Email address contained in the certificate, if present
{cn}	Common Name	Common name contained in the certificate

Variable	Name	Description
{dn}	Distinguished Name	Distinguished name contained in the certificate
{certnotbefore}	Issue Date	Validity date of the certificate
{certnotafter}	Expiration Date	Expiration date of the certificate
{issuerDN}	Issuer DN	Distinguished name of the certificate's issuer
{locations:certstore}	Certificate Store Locations	The server and path location to the certificate store (s) where the certificate resides, if any, for certificates found in certificate stores (e.g. server1.keyexample.com – /opt/test/mystore.jks)
{principal:mail}	Principal's Email	Email address retrieved from Active Directory of the user whose UPN is contained in the SAN field of the certificate, if present
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
{principal:givenname}	orincipal:givenname} Principal's First Name	First name retrieved from Active Directory of the user whose UPN is contained in the SAN field of the certificate, if present
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
{principal:sn} Principal's Last Name		Last name retrieved from Active Directory of the user whose UPN is contained in the SAN field of the certificate, if present
	Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.	
{principal:displayname}	Principal's Display Name	Display name retrieved from Active Directory of the user whose UPN is contained in the SAN field of the certificate, if present
		Note: This substitutable special text token is

Variable	Name	Description
		only supported in environments using Active Directory as an identity provider.
{requester}	Requester	The user account that requested the certificate from the CA, in the form <i>DOMAIN\username</i>
{requester:mail}	Requester's Email	Email address retrieved from Active Directory of the user account that requested the certificate from the CA, if present
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
{requester:givenname}	Requester's First Name	First name retrieved from Active Directory of the user account that requested the certificate from the CA, if present
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
{requester:sn}	Requester's Last Name	Last name retrieved from Active Directory of the user account that requested the certificate from the CA, if present
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
	Requester's Display Name	Display name retrieved from Active Directory of the user account that requested the certificate from the CA, if present
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
{careqid}	Issuing CA / Request ID	A string containing the Issuing CA name and the certificate's Request ID from the CA

Variable	Name	Description
{serial}	Serial Number	The serial number of the certificate
{locations:ssl}	SSL Locations	The server location(s) where the certificate resides, if any, for certificates synchronized using SSL synchronization
{san}	Subject Alternative Name	Subject alternative name(s) contained in the certificate
{template}	Template Name	Name of the certificate template used to create the certificate
{templateshortname}	Template Short Name	Short name (often the name with no spaces) of the certificate template used to create the certificate
{thumbprint}	Thumbprint	The thumbprint (hash) of the certificate
{upn}	User Principal Name	The user principal name (UPN) contained in the subject alternative name (SAN) field of the certificate, if present (e.g. username@keyexample.com)
{metadata: Email-Contact}	Email-Contact	Example of a custom metadata field
	{principal:field} String Value from AD	Locates the object in Active Directory identified by the UPN in the certificate (if present), and substitutes the contents of the attribute named by field. For example:  • {principal:department} • {principal:sAMAccountName} • {principal:manager} • {principal:co}
		partially user defined—you pick the field out of AD to include—and is therefore not available in the <i>Insert special text</i> dropdown; it needs to be typed manually.
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
{requester:field}	String Value	Locates the object in Active Directory identified by

Variable	Name	Description
	from AD	the user or computer account that requested the certificate from the CA, and substitutes the contents of the attribute named by field. For example, for users:  • {requester:department}  • {requester:sAMAccountName}  For computers:  • {requester:operatingSystem}  • {requester:location}  • {requester:managedBy}
		Note: This substitutable special text field is partially user defined—you pick the field out of AD to include—and is therefore not available in the <i>Insert special text</i> dropdown; it needs to be typed manually.
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.

# 2.1.6.2 Pending Certificate Request Alerts

Pending certificate request alerts are used to send email notifications to certificate administrators when a new certificate request that requires approval based on policy on the CA is generated. The alerts can be customized to provide detailed information about the certificate requests.

**Important:** These alerts are **not** used to provide email alerts or run event handlers for certificate requests that require approval based on policies configured in Keyfactor Command workflows. Pending request notification for requests handled by Keyfactor Command workflow are configured within the workflow (see <u>Adding, Copying or Modifying a Workflow Definition on page 237</u>).

Pending certificate requests are generated, for the most part, based on templates that are configured to require manager approval at the CA level.

Figure 128: Certificate Template Requiring Manager Approval

The functionality of pending alerts for certificates requested within Keyfactor Command has been largely replaced by the new Keyfactor Command workflow added in Keyfactor Command version 10 (see <a href="Workflow on page 229">Workflow on page 229</a>). When alerting with Keyfactor Command workflow, templates do not need to be configured to require manager approval. This is because the approval handling is fully controlled within Keyfactor Command. In fact, templates generally should not be configured to require manager approval when using Keyfactor Command workflow, since this would generally require approval both at the Keyfactor Command level and at the CA level, depending on workflow configuration.

Pending alerts are retained for use in these scenarios:

- For customers not wishing to make use of Keyfactor Command workflow.
- For customers still in the process of migrating from CA-based workflow to Keyfactor Command workflow.
- For certificates requested outside of Keyfactor Command using templates that require manager approval.

**Note:** Pending request alerts are supported only for Microsort CAs and select CA gateways. This feature is not supported for EJBCA CAs.

#### **Pending Request Alert Operations**

Pending certificate request alerts are designed to send an email notification to certificate approvers when a certificate request is received that requires approval based on policy on the CA. Pending request alerts can also be sent to the original certificate requesters alerting them that their certificate requests have been sent.

**Important:** These alerts are **not** used to provide email alerts or run event handlers for certificate requests that require approval based on policies configured in Keyfactor Command workflows. Pending request notification for requests handled by Keyfactor Command workflow are configured within the workflow (see <u>Adding, Copying or Modifying a Workflow Definition on page 237</u>).

Pending Request Alert operations include:

- · Creating, editing or deleting a pending alert
- · Configuring an alert schedule
- Copying alerts to create similar alerts for different recipients or situations
- · Testing alerts

**Tip:** In order to be used for PFX enrollment, a template that requires manager approval must be configured with private key retention to allow the private key generated for the request to be downloaded with the certificate after the certificate request is approved (see <a href="Certificate">Certificate</a> <a href="Template Operations on page 382).

# Adding or Modifying a Pending Request Alert

- 1. In the Management Portal, browse to Alerts > Pending Request.
- 2. On the Pending Certificate Request Alerts page, click **Add** from the top menu to create a new alert, or **Edit** from either the top or right click menu, to modify an existing one.
- 3. In the Pending Request Alert Settings dialog, select your **Certificate Template** (or select **All Templates**) in the first dropdown.

Figure 129: Create a New Pending Request Alert

- 4. In the **Display Name** field, enter a name for the alert. This name appears in the pending request alerts grid in the Management Portal.
- 5. In the **Subject** field, enter a subject line for the email message that will be delivered when the alert is triggered. You can use substitutable special text in the subject line. Substitutable special text uses a variable in the alert definition that is replaced by data from the certificate or certificate metadata at processing time. For example, you can enter {rcn} in the alert definition and each alert generated at processing time will contain the specific requested common name of the given certificate request instead of the variable {rcn}.

To add substitutable special text to the subject line; place your cursor where you would like the text to appear on the subject line, select the appropriate variable from the *Insert special text* dropdown, and click *Insert*. Alternately, type the special text variable enclosed in curly braces (e.g. {cn}).

6. In the Message box, enter the body of the email message that will be delivered when the alert is triggered. You can use the Insert special text dropdown below the message window to add substitutable special text to the message. The metadata that appears in the dropdown will depend upon the custom metadata you have defined (see Certificate Metadata on page 712). Place your cursor where you would like the text to appear, select the appropriate variable from the dropdown, and click Insert. Alternately, you can type the special text variable enclosed in curly braces directly. In addition to the substitutable special text fields available in the dropdown, you can also build your own substitutable fields for the requester based on string values from the user or computer Active Directory record. See Table 5: Substitutable Special Text for Pending Request Alerts. If desired, you can format the message body using HTML. For example, you could place the certificate detail information into a table by replacing this text:

```
CN: {rcn}
DN: {rdn}
SAN: {san}

With this HTML code:

CN:{rcn}
CN:{rcn}
CN:{rdn}
CN:{rdn}
CN:{rdn}
CTP<</td>{rdn}
CTP<</td>{rdn}
CTP<</td>{rdn}
CTP<</td>{rdn}
CTP{rdn}
CTP<
```

- 7. The Approval Link substitutable special text field is an important one to include in your alert intended for the administrator responsible for approving or denying the certificate request. This provides a link in the email message that the administrator can click to be taken to an approve/deny page for the certificate in the Management Portal to either approve or deny the request. This certificate-specific approval page cannot be directly accessed within the Management Portal (though you can approve certificate requests in the Management Portal from the Certificate Requests page (see Certificate Requests on page 163).
- 8. Check the **Use handler** box if you would like the alert to trigger an event handler at processing time, select the appropriate handler in the dropdown, and click the **Configure** button to configure the event handler. See <a href="Event Handler Registration on page 741">Event Handler Registration on page 741</a> for more information on using event handlers, and <a href="Adding PowerShell Handlers to Alerts on page 223">Adding PowerShell Handlers</a>.
- 9. In the Recipients section of the page, click Add to add a recipient to the alert. Each alert can have multiple recipients. Recipients should be added one at a time. You can enter specific email addresses and/or use substitutable special text to replace an email address variable with actual email addresses at processing time. The built-in variable can be selected in the Recipient dialog Use a variable from the certificate request dropdown. In addition, you can type a special text variable enclosed in curly braces in the Email field if you have, for example, a metadata field that contains an email address.

Keyfactor Command sends SMS (text) messages by leveraging the email to text gateways that many major mobile carriers provide. Check with your carrier for specific instructions. Keyfactor has tested that AT&T can be addressed using 10-digit-number@txt.att.net (e.g. 4155551212@txt.att.net) and Verizon can be addressed using 10-digit-number@vtext.com (e.g. 2125551212@vtext.com). T-Mobile can be addressed using 10-digit-number@tmomail.net (e.g. 2065551212@tmomail.net), but functionality can be spotty. Reliability of alerting via this method depends on the reliability of the carrier's gateways.

Figure 130: Pending Request Alerts Recipients

10. Click Save to save your pending request alert.

#### Copying a Pending Request Alert

You may use the copy operation to create multiple similar alerts—for example, one to the requester of the certificate and one to the administrator(s) responsible for approving it.

- 1. In the Management Portal, browse to Alerts > Pending Request.
- 2. On the Pending Certificate Request Alerts page, highlight the row in the alerts grid and click **Copy** at the top of the grid, or from the right click menu.
- 3. The Pending Request Alert Settings dialog will pop-up with the details from the selected alert. The display name field will have *Copy* tagged to the end of it to indicate it is a new alert. You may modify the alert as needed and click **Save** to add the new alert, or **Cancel** to cancel the operation.

#### **Deleting a Pending Request Alert**

- 1. In the Management Portal, browse to *Alerts > Pending Request*.
- 2. On the Pending Certificate Request Alerts page, highlight the row in the alerts grid and click **Delete** at the top of the grid, or from the right click menu.
- 3. On the Confirm Operation alert, click **OK** to confirm or **Cancel** to cancel the operation.

# **Configuring a Pending Request Alert Schedule**

After adding your desired pending request alerts, you may configure a schedule to send the alerts.

- 1. In the Management Portal, browse to *Alerts > Pending Request*.
- 2. On the Pending Certificate Request Alerts page, click the Configure button at the top of the Pending Request Alerts page to open the Pending Certificate Request Alert Schedule dialog and configure a monitoring execution schedule. This defines the frequency with which alerts are sent. You can choose to schedule the alerts for:
  - · Daily delivery at a specified time
  - An Interval of anywhere from every 1 minute to every 12 hours
  - Turn Off a previously configured schedule

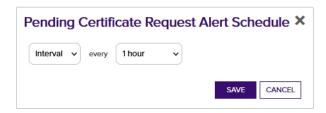

Figure 131: Pending Request Alert Schedule

#### **Testing Pending Request Alerts**

Once the alerts are configured, you may run a test of all or selected alerts to see if they are configured correctly.

- 1. In the Management Portal, browse to Alerts > Pending Request.
- 2. On the Pending Certificate Request Alerts page, either highlight one row in the pending request alerts grid and click the **Test** button at the top of the grid or click the **Test All** button at the top of the grid to test all the alerts.
- 3. In the Pending Alert Test dialog in the Alert Parameters section, click the toggle button for **Send Alerts**, if you would like to deliver email messages as part of the test.
- 4. Click the **Generate** button to begin generating alerts. Depending on the number of certificate requests to process, this may take a few seconds.
- 5. In the Pending Alert Test dialog in the Alert Data and Alert Message sections, you can review the certificate requests found to confirm that the expected requests are appearing and that the substitutable special text is being replaced as expected. Scroll the First, Previous, Next and Last buttons at the bottom of the dialog. The number of alerts generated will display between the navigation buttons.

**Tip:** Alerts are generated for all certificate requests that have not previously been alerted on, unless the system has been configured to send multiple alerts per request. By default, one alert is sent to each recipient for any given request. The number of alerts to send for a given request is configurable with the *Pending Alert Max Reminders* setting in Keyfactor Command application settings (see Application Settings: Console Tab on page 603). If a

certificate remains in a pending state after the configured number of alerts has been sent, no further alerts will be sent.

By default, a maximum of 100 alerts will be generated during a test. The maximum value is configurable with the *Pending Alert Test Result Limit* setting in Keyfactor Command application settings (see <u>Application Settings: Console Tab on page 603</u>). If more than 100 alerts are generated, no email messages will be sent and you'll have the opportunity to view the first 100 alerts generated.

If you're using an event handler, the event handler is run and the handler actions taken (PowerShell script run, event log message) when the test is run. This is true whether or not you click the *Send Alerts* toggle.

Note: HTML does not render in the alert viewer.

Figure 132: Pending Alert Test

Refer to the following table for a complete list of the substitutable special text that can be used to customize alert messages.

Table 5: Substitutable Special Text for Pending Request Alerts

Variable	Name	Description
{apprlink}	Approval Link	Link pointing to the certificate-specific approval page in the Management Portal where the person respons- ible for approving the request can go to approve or deny the request
{reqid}	CMS Request Id	The request ID for the certificate as stored in the Keyfactor Command database. This is not the same as the request ID issued by the CA.
{rcn}	Requested Common Name	Common name contained in the certificate request
{rdn}	Requested Distinguished Name	Distinguished name contained in the certificate request
{requester}	Requester	The user account that requested the certificate from the CA, in the form <i>DOMAIN\username</i>
{requester:mail}	Requester's Email	Email address retrieved from Active Directory of the user account that requested the certificate from the CA, if present
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
{requester:givenname} Requester's First Name		First name retrieved from Active Directory of the user account that requested the certificate from the CA, if present
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
{requester:sn}	uester:sn} Requester's Last Name	Last name retrieved from Active Directory of the user account that requested the certificate from the CA, if present
		Note: This substitutable special text token is

Variable	Name	Description
		only supported in environments using Active Directory as an identity provider.
{requester:displayname}	Requester's Display Name	Display name retrieved from Active Directory of the user account that requested the certificate from the CA, if present
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
{careqid}	Issuing CA / Request ID	A string containing the Issuing CA name and the certificate's Request ID from the CA
{san}	Subject Alternative Name	Subject alternative name(s) contained in the certificate request. There are four possible sources for the SANs that appear here:  • For CSR enrollment, the original SANs included in the CSR.  • Any SANs added through the Keyfactor Command Management Portal. For CSR enrollment, these take the place of the SANs in the CSR if the ATTRIBUTESUBJECTALTNAME2 option is enabled on the CA. See CSR Enrollment on page 136.  • A SAN matching the CN added automatically during enrollment as a result of setting the RFC 2818 compliance flag in the CA configuration. See Adding or Modifying a CA Record on page 355. For PFX enrollment, the user has the option of editing this entry at enrollment time; entry of something is required.  • A SAN matching the CN added automatically by the Keyfactor Command policy module on the CA if the Keyfactor Command RFC 2818 Policy Handler is enabled, if one was not included in the CSR or added manually. See Installing the Keyfactor CA Policy Module Handlers in the Keyfactor Command Server Install-

Variable	Name	Description
		ation Guide.
{subdate}	Submission Date	Date the certificate request was submitted
{template}	Template Name	Name of the certificate template used to create the certificate request
{templateshortname}	Template Short Name	Short name (often the name with no spaces) of the certificate template used to create the certificate request
{metadata: Email-Contact}	Email-Contact	Example of a custom metadata field
{requester:field} String Value from AD	String Value from AD	Locates the object in Active Directory identified by the user or computer account that requested the certificate from the CA, and substitutes the contents of the attribute named by field. For example, for users:
		Note: This substitutable special text field is partially user defined—you pick the field out of AD to include—and is therefore not available in the <i>Insert special text</i> dropdown; it needs to be typed manually.  Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.

# 2.1.6.3 Issued Certificate Request Alerts

Issued certificate request alerts are used to send email notifications to certificate requesters, or other relevant parties, when a new certificate is issued through any CA that syncs to Keyfactor Command. The alerts can be customized to provide detailed information about the certificates.

**Note**: Because Issued Certificate Request Alerts are sent for any CAs synced to Keyfactor Command, it is recommended that any CAs are synced first and then the Issued Certificate Request Alerts set up afterward to avoid a lot of unnecessary emails, upon syncing.

#### **Issued Request Alert Operations**

An issued certificate request alert is designed to send an email notification to a certificate requester when a certificate request he or she made using a certificate template that required manager approval is approved.

Issued Request Alert operations include: creating, editing or deleting an issued request alerts, configuring an alert schedule, and copying alerts to create similar alerts for different recipients or collections.

The issued alert handler runs immediately when an enrollment is approved within the Keyfactor Command platform and also runs via a schedule to pick up any approvals done outside of Keyfactor Command.

# Adding or Modifying an Issued Request Alert

- 1. In the Management Portal, browse to *Alerts > Issued Request*.
- 2. On the Issued Certificate Request Alerts page, click **Add** from the top menu to create a new alert, or **Edit**, from either the top or right click menu, to modify an existing one.
- 3. In the Issued Certificate Alert Settings dialog, select your **Certificate Template** (or select **All Templates**) in the first dropdown.

Figure 133: Create a New Issued Certificate Alert

- 4. In the **Display Name** field, enter a name for the alert. This name appears in the list of issued certificate alerts in the Management Portal.
- 5. In the **Subject** field, enter a subject line for the email message that will be delivered when the alert is triggered. You can use substitutable special text in the subject line. Substitutable special text uses a variable in the alert definition that is replaced by data from the certificate or certificate metadata at processing time. For example, you can enter {cn} in the alert definition and each alert generated will contain the specific common name of the given certificate instead of the variable {cn}.

To add substitutable special text to the subject line; place your cursor where you would like the text to appear on the subject line, select the appropriate variable from the *Insert special text* dropdown, and click *Insert*. Alternately, type the special text variable enclosed in curly braces (e.g. {cn}).

6. In the **Message** box, enter the body of the email message that will be delivered when the alert is triggered. You can use the Insert special text dropdown below the message window to add substitutable special text to the message. The metadata that appears in the dropdown will depend upon the custom metadata you have defined (see Certificate Metadata on page 712). Place your cursor where you would like the text to appear, select the appropriate variable from the dropdown, and click Insert. Alternately, you can type the special text variable enclosed in curly braces directly. In addition to the substitutable special text fields available in the dropdown, you can also build your own substitutable fields for the requester based on string values from the user or computer Active Directory record. See <u>Substitutable Special Text</u> for Issued Certificate Alerts on page 194. If desired, you can format the message body using HTML. For example, you could place the certificate detail information into a table by replacing this text:

```
Serial Number: {serial}
Thumbprint: {thumbprint}
```

SANs: {san}

App Owner: {metadata:AppOwnerFirstName} {metadata:AppOwnerLastName}

With this HTML code:

```
Serial Number: {serial}
Thumbprint: {thumbprint}
SANs: {san}
App Owner: {metadata:AppOwnerFirstName} {metadata:AppOwnerFirstName}
pOwnerLastName}
```

7. The **Download Link** substitutable special text field is an important one to include in your alert intended for the requester of the certificate or the person responsible for installing the certificate. This provides a link in the email message that the user can click to be taken to the Keyfactor Command Management Portal to download the certificate.

Tip: If the users who will receive the issued alerts do not have global Read permissions for Certificates, they will not be able to use the built-in download link. To resolve this, you can build a custom download link as follows:

a. If you do not already have a My Certificates collection, create one using the %ME% special value with a search string of:

```
NetBIOSRequester -eq "%ME%"
```

b. In the Management Portal, browse to the My Certificates collection page and look in the browser's address bar at the end of the URL for the number that has been assigned to the collection. For example, the following URL points to collection 9:

> https://keyfactor.keyexample.com/KeyfactorPortal/CertificateCollection/Edi t?cid=9

- c. Grant the users who will receive the issued alerts *Read* permissions on the *My Certificates* collection (see Certificate Collection Permissions on page 628).
- d. In the message body of the issued alert, create a link that looks like the following, where keyfactor.keyexample.com is the name of your Keyfactor Command server and ID is the correct collection ID for your *My Certificates* collection (e.g. 9):

```
<a
href="https://
keyfactor.keyexample.com
/KeyfactorPortal/CertificateCollection/Edit?cid=ID&query=Thumbprint+-
eq+%22{thumbprint}%22">Download Now</a>
```

- 8. Check the **Use handler** box if you would like the alert to trigger an event handler at processing time, select the appropriate handler in the dropdown, and click the **Configure** button to configure the event handler. See <a href="Event Handler Registration on page 741">Event Handler Registration on page 741</a> for more information on using event handlers, and <a href="Adding PowerShell Handlers to Alerts on page 223">Adding PowerShell Handlers</a>.
- 9. In the Recipients section of the page, click Add to add a recipient to the alert. Each alert can have multiple recipients. Recipients should be added one at a time. You can enter specific email addresses and/or use substitutable special text to replace an email address variable with actual email addresses at processing time. There are three built-in variables that can be selected in the Recipient dialog Use a variable from the certificate request dropdown. In addition, you can type a special text variable enclosed in curly braces in the Email field if you have, for example, a metadata field that contains an email address.

Keyfactor Command sends SMS (text) messages by leveraging the email to text gateways that many major mobile carriers provide. Check with your carrier for specific instructions. Keyfactor has tested that AT&T can be addressed using 10-digit-number@txt.att.net (e.g. 4155551212@txt.att.net) and Verizon can be addressed using 10-digit-number@vtext.com (e.g. 2125551212@v-text.com). T-Mobile can be addressed using 10-digit-number@tmomail.net (e.g. 2065551212@tmomail.net), but functionality can be spotty. Reliability of alerting via this method depends on the reliability of the carrier's gateways.

Figure 134: Issued Certificate Alerts Recipients

10. Click Save to save your issued certificate alert.

# Copying an Issued Request Alert

You may use the copy operation to create multiple similar alerts—for example, one to the requester of the certificate and another with a different message to the person responsible for installing it.

- 1. In the Management Portal, browse to Alerts > Issued Request.
- 2. On the Issued Certificate Request Alerts page, highlight the row in the alerts grid and click **Copy** at the top of the grid, or from the right click menu.
- 3. The Issued Certificate Alert Settings dialog will pop-up with the details from the selected alert. The display name field will have *Copy* tagged to the end of it to o indicate it is a new alert. You may modify the alert as needed and click **Save** to add the new alert, or **Cancel** to cancel the operation.

#### Deleting an Issued Request Alert

- 1. In the Management Portal, browse to Alerts > Issued Request.
- 2. On the Issued Certificate Request Alerts page, highlight the row in the alerts grid and click **Delete** at the top of the grid, or from the right click menu.
- 3. On the Confirm Operation alert, click **OK** to confirm or **Cancel** to cancel the operation.

#### Configuring an Issued Request Alert Schedule

After adding your desired issued alerts, you may configure a schedule to send the alerts.

- 1. In the Management Portal, browse to Alerts > Issued Request.
- 2. On the Issued Certificate Request Alerts page, click the **Configure** button at the top of the Issued Certificate Request Alerts page to configure a monitoring execution schedule. This defines the frequency with which alerts are sent. You can choose to schedule the alerts either

for daily delivery at a specified time or at intervals of anywhere from every 1 minute to every 12 hours. A short interval is the most common configuration.

Figure 135: Issued Alert Schedule

Refer to the following table for a complete list of the substitutable special text that can be used to customize alert messages.

Table 6: Substitutable Special Text for Issued Certificate Alerts

Variable	Name	Description
{dnldlink}	Download Link	Link pointing to the Certificate Requests page in the Keyfactor Command Management Portal where the certificate requester or the person responsible for installing the certificate can go to download the certificate. The certificate will be available only in a .cer-/.crt format (without the private key) unless private key retention has been enabled on the template (see Certificate Templates on page 380).
{certemail}	Email Address in Certificate	Email address contained in the certificate, if present
{cn}	Common Name	Common name contained in the certificate
{dn}	Distinguished Name	Distinguished name contained in the certificate
{certnotbefore}	Issue Date	Validity date of the certificate
{certnotafter}	Expiration Date	Expiration date of the certificate
{issuerDN}	Issuer DN	Distinguished name of the certificate's issuer
{principal:mail}	Principal's Email	Email address retrieved from Active Directory of the user whose UPN is contained in the SAN field of the certificate, if present
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.

Variable	Name	Description
{principal:givenname}	Principal's First Name	First name retrieved from Active Directory of the user whose UPN is contained in the SAN field of the certificate, if present
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
{principal:sn}	Principal's Last Name	Last name retrieved from Active Directory of the user whose UPN is contained in the SAN field of the certificate, if present
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
{principal:displayname}	Principal's Display Name	Display name retrieved from Active Directory of the user whose UPN is contained in the SAN field of the certificate, if present
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
{requester}	Requester	The user account that requested the certificate from the CA, in the form DOMAIN\username
{requester:mail}	Requester's Email	Email address retrieved from Active Directory of the user account that requested the certificate from the CA, if present
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
{requester:givenname} Requester's First Name		First name retrieved from Active Directory of the user account that requested the certificate from the CA, if present
	Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.	

Variable	Name	Description
{requester:sn}	Requester's Last Name	Last name retrieved from Active Directory of the user account that requested the certificate from the CA, if present
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
{requester:displayname}	Requester's Display Name	Display name retrieved from Active Directory of the user account that requested the certificate from the CA, if present
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
{careqid}	Issuing CA / Request ID	A string containing the Issuing CA name and the certificate's Request ID from the CA
{serial}	Serial Number	The serial number of the certificate
{san}	Subject Altern- ative Name	Subject alternative name(s) contained in the certificate
{template}	Template Name	Name of the certificate template used to create the certificate
{templateshortname}	Template Short Name	Short name (often the name with no spaces) of the certificate template used to create the certificate request
{thumbprint}	Thumbprint	The thumbprint (hash) of the certificate
{upn}	User Principal Name	The user principal name (UPN) contained in the subject alternative name (SAN) field of the certificate, if present (e.g. username@keyexample.com)
{metadata:Email-Contact}	Email-Contact	Example of a custom metadata field
{principal:field}	String Value from AD	Locates the object in Active Directory identified by the UPN in the certificate (if present), and substitutes the contents of the attribute named by <i>field</i> . For example:  • {principal:department}

Variable	Name	Description
		<ul><li> {principal:sAMAccountName}</li><li> {principal:manager}</li><li> {principal:co}</li></ul>
		Note: This substitutable special text field is partially user defined—you pick the field out of AD to include—and is therefore not available in the <i>Insert special text</i> dropdown; it needs to be typed manually.
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
{requester:field} String Value from AD	Locates the object in Active Directory identified by the user or computer account that requested the certificate from the CA, and substitutes the contents of the attribute named by field. For example, for users:  • {requester:department}  • {requester:sAMAccountName}  For computers:  • {requester:operatingSystem}  • {requester:location}  • {requester:managedBy}	
		partially user defined—you pick the field out of AD to include—and is therefore not available in the <i>Insert special text</i> dropdown; it needs to be typed manually.
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.

# 2.1.6.4 Denied Certificate Request Alerts

Denied certificate request alerts are used to send email notifications to certificate requesters or other relevant parties when a certificate request that required approval is denied through Keyfactor

Command. The alerts can be customized to provide detailed information about the certificate requests.

Important: These alerts are not used to provide email alerts or run event handlers for certificate requests that require approval based on policies configured in Keyfactor Command workflows. Denial notification for requests handled by Keyfactor Command workflow are configured within the workflow (see Adding, Copying or Modifying a Workflow Definition on page 237).

Unlike pending certificate request alerts that are sent on a configurable schedule, denied certificate request alerts are sent immediately after the certificate request is denied through Keyfactor Command.

Tip: Click the help icon (3) next to the page title to open the embedded web copy of the Keyfactor Command Documentation Suite to this section.

You can also find the help icon at the top of the page next to the Log Out button. From here you can choose to open either the Keyfactor Command Documentation Suite at the home page or the Keyfactor API Endpoint Utility.

#### **Denied Certificate Request Alert Operations**

A denied certificate request alert is designed to send an email notification to a certificate requester when a certificate request he or she made using a certificate template that required manager approval is denied. It can include a comment from the administrator who denied the request indicating why the request was denied. From the Denied Certificate Request Alert page you can add a new alert, edit an existing one, delete an alert and copy an existing alert to form a template for a new alert.

# Adding or Modifying a Denied Certificate Request Alert

- 1. In the Management Portal, browse to *Alerts > Denied Request*.
- 2. On the Denied Certificate Requests Alerts page, click Add at the top of the grid to create a new alert, or click Edit to modify an existing one (Edit is also available from the right click menu).
- 3. In the Denied Certificate Request Alert Settings dialog, select your Certificate Template (or select All Templates) in the first dropdown.

Figure 136: Create a New Denied Certificate Request Alert

- 4. In the **Display Name** field, enter a name for the alert. This name appears in the list of denied certificate request alerts in the Management Portal.
- 5. In the **Subject** field, enter a subject line for the email message that will be delivered when the alert is triggered. You can use substitutable special text in the subject line. Substitutable special text uses a variable in the alert definition that is replaced by data from the certificate or certificate metadata at processing time. For example, you can enter {rcn} in the alert definition and each alert generated will contain the specific requested common name of the given request instead of the variable {rcn}.

To add substitutable special text to the subject line; place your cursor where you would like the text to appear on the subject line, select the appropriate variable from the *Insert special text* 

- dropdown, and click **Insert**. Alternately, type the special text variable enclosed in curly braces (e.g. {cn}).
- 6. In the Message box, enter the body of the email message that will be delivered when the alert is triggered. You can use the Insert special text dropdown below the message window to add substitutable special text to the message. The metadata that appears in the dropdown will depend upon the custom metadata you have defined (see Certificate Metadata on page 712). Place your cursor where you would like the text to appear, select the appropriate variable from the dropdown, and click Insert. Alternately, you can type the special text variable enclosed in curly braces directly. In addition to the substitutable special text fields available in the dropdown, you can also build your own substitutable fields for the requester based on string values from the user or computer Active Directory record. See Table 7: Substitutable Special Text for Denied Certificate Request Alerts. If desired, you can format the message body using HTML.
- 7. The **Denial Comments** substitutable special text field is an important one to include in your alert intended for the requester of the certificate. This provides the comment the administrator made at the time he or she denied the certificate request (see Certificate Requests on page 163).
- 8. Check the **Use handler** box if you would like the alert to trigger an event handler at processing time, select the appropriate handler in the dropdown, and click the **Configure** button to configure the event handler. See <a href="Event Handler Registration on page 741">Event Handler Registration on page 741</a> for more information on using event handlers, and <a href="Adding PowerShell Handlers to Alerts on page 223">Adding PowerShell Handlers</a>.
- 9. In the Recipients section of the page, click Add to add a recipient to the alert. Each alert can have multiple recipients. Recipients should be added one at a time. You can enter specific email addresses and/or use substitutable special text to replace an email address variable with actual email addresses at processing time. There are three built-in variables that can be selected in the Recipient dialog Use a variable from the certificate request dropdown. In addition, you can type a special text variable enclosed in curly braces in the Email field if you have, for example, a metadata field that contains an email address.

Keyfactor Command sends SMS (text) messages by leveraging the email to text gateways that many major mobile carriers provide. Check with your carrier for specific instructions. Keyfactor has tested that AT&T can be addressed using 10-digit-number@txt.att.net (e.g. 4155551212@txt.att.net) and Verizon can be addressed using 10-digit-number@vtext.com (e.g. 2125551212@v-text.com). T-Mobile can be addressed using 10-digit-number@tmomail.net (e.g. 2065551212@tmomail.net), but functionality can be spotty. Reliability of alerting via this method depends on the reliability of the carrier's gateways.

Figure 137: Denied Certificate Request Alerts Recipients

10. Click Save to save your denied certificate request alert.

# Copying a Denied Certificate Request Alert

You may use the copy operation to create multiple similar alerts—for example, one to the requester of the certificate and another with a different message to the application owner for whom it was intended.

- 1. In the Management Portal, browse to Alerts > Denied Request.
- 2. On the Denied Certificate Requests Alerts page, highlight the row in the denied certificate request alerts grid and click **Copy** at the top of the grid, or from the right click menu.
- 3. The Denied Certificate Request Alert Settings dialog will pop-up with the details from the selected alert. The display name field will have *Copy* tagged to the end of it to indicate it is a new alert. You may modify the alert as needed and click **Save** to add the new alert, or **Cancel** to cancel the operation.

#### Deleting a Denied Certificate Request Alert

- 1. In the Management Portal, browse to *Alerts > Denied Request*.
- 2. On the Denied Certificate Requests Alerts page, highlight the row in the denied certificate request alerts grid and click **Delete** at the top of the grid, or from the right click menu.
- 3. On the Confirm Operation alert, click **OK** to confirm or **Cancel** to cancel the operation.

Refer to the following table for a complete list of the substitutable special text that can be used to customize alert messages.

Table 7: Substitutable Special Text for Denied Certificate Request Alerts

Variable	Name	Description
{cmnt}	Denial	Comments provided by the administrator responsible

Variable	Name	Description
	Comments	for approving or denying the certificate request at the time the request was denied
{ren}	Requested Common Name	Common name contained in the certificate request
{rdn}	Requested Distinguished Name	Distinguished name contained in the certificate request
{requester:mail}	Requester's Email	Email address retrieved from Active Directory of the user account that requested the certificate from the CA, if present
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
{requester:givenname}	Requester's First Name	First name retrieved from Active Directory of the user account that requested the certificate from the CA, if present
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
{requester:sn}	Requester's Last Name	Last name retrieved from Active Directory of the user account that requested the certificate from the CA, if present
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
{requester:displayname}	Requester's Display Name	Display name retrieved from Active Directory of the user account that requested the certificate from the CA, if present
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.

Variable	Name	Description
{careqid}	Issuing CA / Request ID	A string containing the Issuing CA name and the certificate's Request ID from the CA
{san}	Subject Altern- ative Name	Subject alternative name(s) contained in the certificate request
{subdate}	Submission Date	Date the certificate request was submitted
{template}	Template Name	Name of the certificate template used to create the certificate request
{templateshortname}	Template Short Name	Short name (often the name with no spaces) of the certificate template used to create the certificate request
{metadata:Email-Contact}	Email-Contact	Example of a custom metadata field
{requester:field}	String Value from AD	Locates the object in Active Directory identified by the user or computer account that requested the certificate from the CA, and substitutes the contents of the attribute named by field. For example, for users:  • {requester:department}  • {requester:sAMAccountName}  For computers:  • {requester:operatingSystem}  • {requester:location}  This substitutable special text field is partially user defined—you pick the field out of AD to include—and is therefore not available in the Insert special text dropdown; it needs to be typed manually.
		Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.

# 2.1.6.5 Key Rotation Alerts

Key rotation alerts are used to send email notifications to SSH key users and/or administrators when a key is nearing the end of the key lifetime. The default key lifetime is 365 days, but this setting is configurable (see <a href="Application Settings: SSH Tab on page 621">Application Settings: SSH Tab on page 621</a>). Key rotation alerts apply to both user keys (see <a href="My SSH Key on page 532">My SSH Key on page 532</a>) and service account keys (see <a href="Service Account Keys on page 543">Service Account Keys on page 543</a>) generated within Keyfactor Command.

The alerts can be customized to provide detailed information about the keys along with, for example, instructions to users on how to enroll for a replacement key.

## **Key Rotation Alert Operations**

Key Rotation alert operations include: creating, editing or deleting a key rotation alert, configuring an alert schedule, copying alerts to create similar alerts for different recipients or collections, and testing alerts.

# Adding or Modifying a Key Rotation Alert

- 1. In the Management Portal, browse to Alerts > Key Rotation.
- 2. On the Key Rotation Alerts page, click **Add** from the top menu to create a new alert, or **Edit**, from either the top or right click menu, to modify an existing one.
- 3. In the Key Rotation Alert Settings dialog, select a **Timeframe** for the alert by choosing the number of days, weeks, or months to define the alert period.

**Note:** When the alert is stored in the database, weeks are converted to 7 days and months are converted to 30 days.

4. In the Key Rotation Alert Settings dialog, enter a **Display Name** for the alert. This name appears in the list of key rotation alerts in the Management Portal.

Figure 138: Key Rotation Alerts Recipients

5. In the **Subject** field, enter a subject line for the email message that will be delivered when the alert is triggered. You can use substitutable special text in the subject line. Substitutable special text uses a variable in the alert definition that is replaced by data from the key record at processing time. For example, you can enter {fingerprint} in the alert definition and each alert generated at processing time will contain the specific fingerprint of the given key instead of the variable {fingerprint}. To add substitutable special text to the subject line, type the special text variable enclosed in curly braces (e.g. {fingerprint}).

Figure 139: Substitutable Special Text for Key Rotation Alerts

6. In the Message box, enter the body of the email message that will be delivered when the alert is triggered. You can use the Insert special text dropdown below the message window to add substitutable special text to the message. Place your cursor where you would like the text to appear, select the appropriate variable from the dropdown, and click Insert. Alternately, you can type the special text variable enclosed in curly braces directly. If desired, you can format the message body using HTML. For example, you could place the key detail information into a table by replacing this text:

- 7. Check the **Use handler** box if you would like the alert to trigger an event handler at processing time, select the appropriate handler in the dropdown, and click the **Configure** button to configure the event handler. See <a href="Event Handler Registration on page 741">Event Handler Registration on page 741</a> for more information on using event handlers, and <a href="Adding PowerShell Handlers to Alerts on page 223">Adding PowerShell Handlers</a>.
- 8. Click Save to save your key rotation alert.

# Copying an Existing Key Rotation Alert

You may use the copy operation to create multiple similar alerts—for example, one for a warning a month in advance of the stale date of keys and another shortly before the keys become stale.

- 1. In the Management Portal, browse to Alerts > Key Rotation.
- 2. On the Key Rotation Alerts page, highlight the row in the alerts grid and click **Copy** at the top of the grid, or from the right click menu.
- 3. The Key Rotation Alert Settings dialog will pop-up with the details from the selected alert. The display name field will have *Copy* tagged to the end of it to indicate it is a new alert. You may modify the alert as needed and click **Save** to add the new alert, or **Cancel** to cancel the operation.

## **Deleting a Key Rotation Alert**

- 1. In the Management Portal, browse to Alerts > Key Rotation.
- 2. On the Key Rotation Alerts page, highlight the row in the alerts grid and click **Delete** at the top of the grid, or from the right click menu.
- 3. On the Confirm Operation alert, click **OK** to confirm or **Cancel** to cancel the operation.

## Configuring a Key Rotation Alert Schedule

After adding your desired key rotation alerts, you may configure a schedule to send the alerts.

- 1. In the Management Portal, browse to Alerts > Key Rotation.
- 2. On the Key Rotation Alerts page, click the **Configure** button at the top of the Key Rotation Alerts page to configure an alert execution schedule. This defines the frequency with which key rotation alerts are sent. This type of alert is scheduled for daily delivery at a specified time.

Figure 140: Key Rotation Alert Schedule

## **Testing Key Rotation Alerts**

Once the alerts are configured, you may run a test of all or selected alerts to see if they are configured correctly.

- 1. In the Management Portal, browse to *Alerts > Key Rotation*.
- 2. On the Key Rotation Alerts page, either highlight one row in the expiration alert grid and click the **Test** button at the top of the grid or click the **Test All** button at the top of the grid to test all the alerts.
- 3. In the Key Rotation Alert Viewer dialog in the Alert Parameters section, select a **Start Date** and **End Date** for testing. You can use this option to simulate running the alerts a month from now instead of today, for example, or put in a broad date range to be sure you pick up some expiring certificates for testing purposes.
- 4. In the Key Rotation Alert Viewer dialog in the Alert Parameters section, click the toggle button for **Send Alerts** if you would like to deliver email messages as part of the test.
- 5. Click the **Generate** button to begin generating alerts. Depending on the number of keys to process, this may take a few seconds.
- 6. In the Key Rotation Alert Viewer dialog in the Alert Data and Alert Message sections, you can review the keys found to confirm that the expected keys are appearing and that the substitutable special text is being replaced as expected. Scroll through the alerts using the First, Previous, Next and Last buttons at the bottom of the dialog. The number of alerts generated will display between the navigation buttons.

**Tip:** Alerts are generated when an SSH key is approaching or has reached its stale date as defined by the timeframe configured in the alert and the SSH key lifetime (the *Key Lifetime (days)* application setting).

By default, a maximum of 100 alerts will be generated during a test. The maximum value is configurable with the *Key Rotation Alert Test Result Limit* setting in Keyfactor Command application settings (see <u>Application Settings: Console Tab on page 603</u> in the *Keyfactor Command Reference Guide*). If more than 100 alerts are generated, no email messages will be sent and you'll have the opportunity to view the first 100 alerts generated.

If you're using an event handler, the event handler is run and the handler actions taken (PowerShell script run, event log message written) when the test is run. This is true whether or not you click the Send Alerts toggle.

**Note:** HTML does not render in the alert viewer.

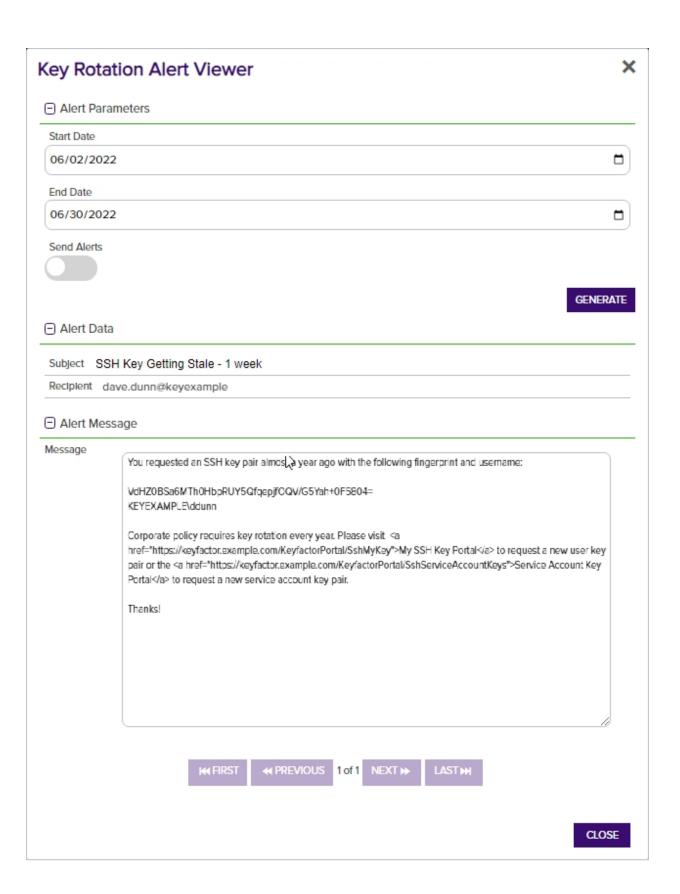

Figure 141: Key Rotation Alert Viewer

Refer to the following table for a complete list of the substitutable special text that can be used to customize alert messages.

Table 8: Substitutable Special Text for Key Rotation Alerts

Variable	Name	Description
{comment}	Comment in Key	The user-defined descriptive comment, if any, on the key.  Although entry of an email address in the comment field of an SSH key is traditional, this is not a required format. The comment may can contain any characters supported for string fields, including spaces and most punctuation marks.
{fingerprint}	Fingerprint of Key	The fingerprint of the public key. Each SSH public key has a single cryptographic fingerprint that can be used to uniquely identify the key.
{keylength}	Key Length	The key length for the key. The key length depends on the key type selected. Keyfactor Command supports 256 bits for Ed25519 and ECDSA and 2048 or 4096 bits for RSA.
{keytype}	Кеу Туре	A number of cryptographic algorithms can be used to generate SSH keys. Keyfactor Command supports RSA, Ed25519, and ECDSA. RSA keys are more universally supported, and this is the default key type when generating a new key.
{serverlogons}	Number of Server Logons for Key	The number of Linux logons associated with the key, if any, granting the holder of the private key pair logon access on the server where the Linux logon resides.
{username}	Username associated with Key	The username of the user or service account associated with the key. For a user, the username is in the form of an Active Directory account (e.g. DOMAIN\username). For a service account, the username is made up of the username and client hostname entered when the service account key was created (e.g. myapp@appsrvr75).

## 2.1.6.6 Revocation Monitoring

Certificate revocation list (CRL) and online certificate status protocol (OCSP) locations are configured in the Revocation Monitoring section of the Management Portal to allow for email notifications when CRLs are near or at expiration, and for display on the Revocation Monitoring dashboard (see <a href="Dashboard: Revocation Monitoring on page 17">Dashboard: Revocation Monitoring on page 17</a>). When revocation notifications are sent via email, matching events are written to the Windows event log on the Keyfactor Command server. The alert time-frame is calculated based on the date that the CRL expires, rather than the Next

Publish date. This allows for users to define their own alerts and log entries (thus determining their own definition of *stale*).

CRL monitoring and notification provides information on:

- The status of the CRL endpoint's responsiveness (e.g. is the file missing or the web site unreachable).
- · Warning of upcoming expiration for a CRL.
- Notification of expired CRLs.

OCSP monitoring and notification provides only information on whether or not the OCSP endpoint is responsive. Expiration is not relevant for OSCP.

**Tip:** Click the help icon (2) next to the page title to open the embedded web copy of the *Keyfactor Command Documentation Suite* to this section.

You can also find the help icon at the top of the page next to the **Log Out** button. From here you can choose to open either the *Keyfactor Command Documentation Suite* at the home page or the *Keyfactor API Endpoint Utility*.

## **Revocation Monitoring Location Operations**

From the Revocation Monitoring page on the Keyfactor Command Management Portal you can view and edit existing location endpoints, add new locations, delete an endpoint, test revocation monitoring location alert email notifications, and monitor location endpoint responsiveness.

## Adding or Modifying a Revocation Monitoring Location

1. In the Management Portal, browse to Alerts > Revocation Monitoring.

# Revocation Monitoring © Configure Revocation Monitoring to send alerts when Cf

Configure Revocation Monitoring to send alerts when CRLs are stale, expired or within a customizable period before expiration, or when CRL or OCSP endpoints are unreachable

Figure 142: Revocation Monitoring Grid

2. On the Revocation Monitoring page, click **Add** to create a new monitoring location, or **Edit** to modify an existing one, and then populate the *Revocation Endpoint Settings* dialog appropriately for the type of revocation endpoint using the information below:

#### For a CRL location:

- a. In the Revocation Endpoint Settings dialog, type a **Display Name** for the CRL location. This name appears on the Revocation Monitoring grid and on the Management Portal dashboard.
- b. Select CRL in the **Endpoint Type** dropdown.
- c. In the Location field, type a URL for the CRL location. This can be either an HTTP location or an LDAP location. Be sure to monitor the CRL locations that are in use by applications in your environment—if you're monitoring LDAP locations but applications are using an HTTP location, you're not going to receive any warning if a CRL fails to publish to the HTTP location.

Important: Because a "+" (plus sign) in a URL can represent either a space or a "+" Keyfactor Command has chosen to read "+" as a space. For CRL URLs that require a "+" (plus sign), rather than a space, replace plus signs in your CRL's URL with "%2B". Only replace the plus signs you don't wish to be treated as a space.

- d. In the **Email Reminder** section of the page, check the **Warn** box and set the number of days ahead of expiration that email reminders should begin to be sent.
- e. In the **Show on Dashboard** section of the page, check the **Warn** box and set the number of weeks, days or hours ahead of expiration for warning flags to begin appearing on the Management Portal dashboard (see Dashboard: Revocation Monitoring on page 17).
- f. In the **Monitoring Execution Schedule** section of the page, configure a monitoring execution schedule. This defines the frequency with which locations are checked and alerts sent. You can choose to schedule the alert for this location either for daily delivery at a specified time or at intervals of anywhere from every 1 minute to every 12 hours. A daily schedule is the most common configuration. Schedules are configured separately for each endpoint.
- g. In the **Recipients** section of the page, add email addresses of the users and/or groups who should receive email notifications when CRLs are approaching expiration or are unreachable. Recipient lists are configured separately for each endpoint.
  - Keyfactor Command sends SMS (text) messages by leveraging the email to text gateways that many major mobile carriers provide. Check with your carrier for specific instructions. Keyfactor has tested that AT&T can be addressed using 10-digit-number@txt.att.net (e.g. 4155551212@txt.att.net) and Verizon can be addressed using 10-digit-number-@vtext.com (e.g. 2125551212@vtext.com). T-Mobile can be addressed using 10-digit-number@tmomail.net (e.g. 2065551212@tmomail.net), but functionality can be spotty. Reliability of alerting via this method depends on the reliability of the carrier's gateways.

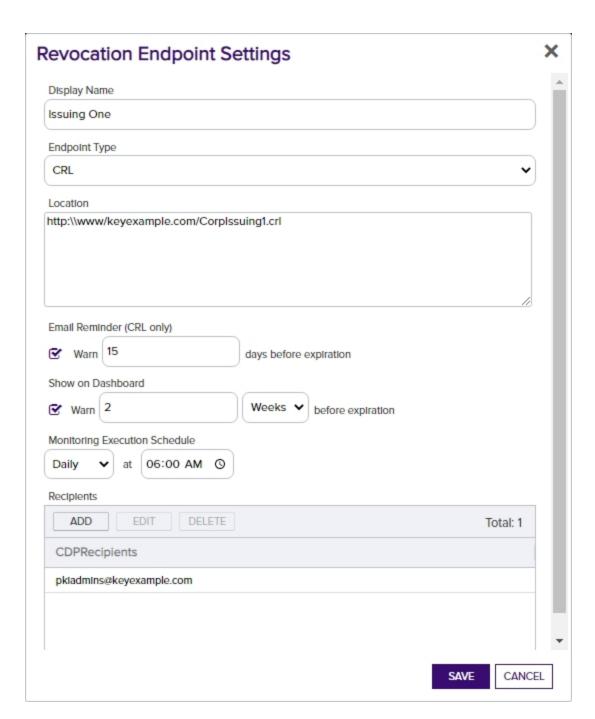

Figure 143: CRL Monitoring Details

#### For an OCSP location:

- a. In the Revocation Endpoint Settings dialog, type a **Display Name** for the OCSP location. This name appears on the Revocation Monitoring grid and on the Management Portal dashboard.
- b. Select OCSP in the **Endpoint Type** dropdown.
- c. Keyfactor Command offers two options to retrieve endpoint information for OCSP:
  - Resolve it based on a certificate authority defined in Keyfactor Command (see
     <u>Adding or Modifying a CA Record on page 355</u>). This option is only available for
     Microsoft CAs in the forest in which Keyfactor Command is installed or EJBCA CAs
     installed on the same network as the Keyfactor Command server. When you use this
     option, a request is sent for information from the Keyfactor Command server to the
     CA. For Microsoft CAs, this a DCOM request. For EJBCA CAs, this is a REST
     request.
  - Import it from a certificate issued by the certificate authority to be monitored. This can be any certificate issued by the CA and containing the OCSP information. The certificate needs to be a base-64 encoded PEM file (.cer/.crt).

In the **CA Info** field, select the **CMS** radio button to automatically retrieve the CA certificate information from Keyfactor Command or select the **File** radio button to upload a file with the CA certificate information.

- If you select CMS, pick the desired CA from the CA dropdown and then click the Resolve button to retrieve the certificate authority information.
- If you select File, click the Upload button, browse to locate the file containing a certificate issued by the desired CA and open it.
  - With either method of retrieving the information, you should see the full certificate authority name and authority key ID populate below the CA dropdown. The serial number field will populate for uploaded files.
- d. In the **Location** section of the page, enter the full URL to the OCSP responder servicing this certificate authority's CRL.
- e. In the **Show on Dashboard** section of the page, check the box to include this OCSP location on the Management Portal dashboard (see <u>Dashboard: Revocation Monitoring on page 17</u>).
- f. In the **Monitoring Execution Schedule** section of the page, configure a monitoring execution schedule. This defines the frequency with which locations are checked and alerts sent. You can choose to schedule the alert for this location either for daily delivery at a specified time or at intervals of anywhere from every 1 minute to every 12 hours. A daily

- schedule is the most common configuration. Schedules are configured separately for each endpoint.
- g. In the **Recipients** section of the page, add email addresses of the users and/or groups who should receive email notifications when OCSP endpoints are unreachable. Recipient lists are configured separately for each endpoint.

Keyfactor Command sends SMS (text) messages by leveraging the email to text gateways that many major mobile carriers provide. Check with your carrier for specific instructions. Keyfactor has tested that AT&T can be addressed using 10-digit-number@txt.att.net (e.g. 4155551212@txt.att.net) and Verizon can be addressed using 10-digit-number-@vtext.com (e.g. 2125551212@vtext.com). T-Mobile can be addressed using 10-digit-number@tmomail.net (e.g. 2065551212@tmomail.net), but functionality can be spotty. Reliability of alerting via this method depends on the reliability of the carrier's gateways.

3. Click Save to save the endpoint location, or the changes. Click Cancel to cancel.

# **Deleting a Revocation Monitoring Location**

- 1. In the Management Portal, browse to Alerts > Revocation Monitoring.
- 2. On the Revocation Monitoring page, highlight the row in the grid and click **Delete** at the top of the grid, or from the right click menu.
- 3. On the Confirm Operation alert, click **OK** to confirm or **Cancel** to cancel the operation.

## **Testing Revocation Alerts**

- 1. In the Management Portal, browse to Alerts > Revocation Monitoring.
- 2. On the Revocation Monitoring page, click the **Test All** button at the top of the grid, or select a specific location from the grid and click **Test** from the top of the grid or the right click menu.
- 3. In the Revocation Monitoring Test dialog in the Alert Parameters section, select an **End Date** for testing. You can use this option to simulate running the alerts a month from now instead of today, for example, or put in a date far in the future to be sure you pick up some expiring CRLs for testing purposes.
- 4. In the Revocation Monitoring Test dialog in the Alert Parameters section, click the toggle button for **Send Alerts** if you would like to deliver email messages as part of the test.
- 5. Click the **Generate** button to begin generating alerts. Depending on the number of endpoints to process, this may take a few seconds.
- 6. In the Revocation Monitoring Test dialog in the Alert Data and Alert Message sections, you can review the alerts to confirm that the expected CRLs and OCSP endpoints are appearing. Scroll through the alerts using the **First**, **Previous**, **Next** and **Last** buttons at the bottom of the dialog. The number of alerts generated will display between the navigation buttons.

**Tip:** Alerts are generated when a CRL is expired or in the warning period as defined by the number of days configured in the *Email Reminder* setting. For example, if you had a CRL that expired on June 30 and configured the email reminder period to 15 days before expiration, the warning status would begin for that CRL on June 15 and CRL alerts would be generated. A warning will also appear for any CRL or OCSP locations that produced an error or couldn't be resolved.

When alerts are tested or sent on a schedule, corresponding message are also written to the system event log on the server where the Keyfactor Command service runs. For testing, this is true whether or not you click the *Send Alerts* toggle. Information is logged to the event log for both locations that are in a good state (e.g. CRL resolves and is not in a warning or expired state or response from OCSP) and locations that are in an error state (e.g. CRL resolves but is in the warning period or expired, CRL is expired, CRL or OCSP location does not resolve).

For specific Windows event ID information, see <u>Keyfactor Command Windows Event IDs on</u> page 806.

Figure 145: Test Revocation Monitoring

Figure 146: Revocation Monitoring Event Log Messages

## 2.1.6.7 Using Event Handlers

A given expiration, pending, issued or denied alert can have only one event handler action associated with it. For example, an alert can run one PowerShell script but not also a second PowerShell script or also an event logging task. Alerts configured with a PowerShell or renewal event handler can also send out email messages. However, be aware that your PowerShell script will run once for

every certificate and every email recipient, so if your alert has three email recipients, your script will run three times for each certificate. If this is not the desired behavior, you can set up separate alerts for email messages and your PowerShell script. Alerts configured with an event logger event handler will log events to the event log instead of sending email messages. If you want to both log to the event log and send email messages for a given alert configuration, you need to set up two separate alerts.

**Tip:** PowerShell handlers will run in different security contexts depending on how they are triggered. If they are triggered by the Management Portal/Keyfactor API they will run in the context of the Keyfactor API application pool account. If they are triggered by a task scheduled in the Keyfactor Command Management Portal, they will run in the context of the Keyfactor Command Service account. Keep this in mind if your configuration of the Power-Shell script is going to use Windows Authentication to reach back into Keyfactor Command, or elsewhere.

#### **PowerShell Scripts**

PowerShell scripts used in alert event handlers and workflows are stored in the Keyfactor Command database and need to first be imported into the database using the *POST/Extensions/Scripts* API endpoint (see *POST/Extensions/Scripts* in the *Keyfactor API Reference Guide*) before they will be available for use in alerts and workflows. Scripts can only be managed through the Keyfactor API.

## **Use with Workflow**

Within workflow step definitions, PowerShell can be used with the step types **Set Variable Data** and **Use Custom PowerShell**. Only the **Use Custom PowerShell** step uses the /Extensions/Scripts API endpoints. Once imported, scripts will be available for selection from a dropdown in the workflow workspace on the step dialogue when creating a step of this type or with the workflow definition API endpoints. The **Set Variable Data** step allows PowerShell commands to be added to the step directly, thus are not stored in the database as scripts, but only with the workflow step. Many examples of using scripts with workflow can be found in <u>Workflow Definitions Configuration Parameters on page 251</u>.

#### **Use with Event Handlers**

Event handler scripts are available for use in multiple Keyfactor Command areas, including:

- Expiration Alerts on page 167
   Create email notifications that alert administrators and/or end users when certificates are coming up for expiration.
- <u>Pending Certificate Request Alerts on page 178</u>
   Create email notifications that alert PKI administrators when a new pending certificate request is made.
- <u>Issued Certificate Request Alerts on page 188</u>
  Create email notifications that alert a certificate requester when a certificate he or she requested has been issued.

- <u>Denied Certificate Request Alerts on page 197</u>
   Create email notifications that alert a certificate requester when a certificate he or she requested has been denied.
- Key Rotation Alerts on page 203
   Create email notifications that alert end users and PKI administrators when an SSH key is nearing the end of its lifetime.

Event handler scripts used in any of these areas need to be imported into Keyfactor Command before they will be available for use in the alerts.

To create a PowerShell script that works with the event handlers, there are just a few things to keep in mind:

• You need to declare the \$context hashtable at the start of the script with this line:

[hashtable]\$context

• Parameters you want to use in your script are referenced using the \$context syntax as follows (where MyName is the name you gave to the parameter in the event handler configuration or the name of the built-in parameter from Table 9: PowerShell Event Handler Special Fields):

\$context["MyName"]

Table 9: PowerShell Event Handler Special Fields

Name	Alert Type	Description
SendEmail	All	If true, email messages are sent in addition to processing of the Power-Shell script.
Subject	All	The full subject line of the alert.
Message	All	The full message body of the alert.
Recipient	All	The recipient of the alert. Alerts configured with more than one recipient will execute the PowerShell script multiple times—once for each recipient and each certificate or request.
Certificate	Expiration Only	For internal Keyfactor use only.
First Recip- ient	Expiration Only	If true and the alert has multiple recipients configured, this output is for the first recipient for the given certificate. Subsequent output for the same certificate and different recipients will show false for this value.

Tip: A sample PowerShell script is installed with Keyfactor Command in the ExtensionLibrary directory, located by default at C:\Program Files\Keyfactor\Keyfactor Platform\ExtensionLibrary\net6.0\SampleEventHandler.ps1.

Below is a simple script that takes as inputs all the parameters you defined in your event handler configuration as well as the built-in parameters and outputs them to a file along with a comment and the date, with configuration to skip output of a defined list of the built-in parameters:

```
# This is a sample script that can be set up as a Keyfactor Command event handler. The script will
# data passed to the handler to a text file. This script will be called for the combination of each
# certificate involved in the corresponding event and each configured email recipient.
# In order to communicate with the extension script, the Keyfactor Command event handler framework
injects
# a hashtable into the PowerShell runspace. This hashtable will include the fields configured by the
# administrator when setting up the handler as well as some built-in system fields used for commu-
nication
# with the handler.
# The following fields are provided for communication with the handler:
# Subject -
                  Email subject line that will be sent if the alert has the email subject
configured
# Message -
                   Email body that will be sent if the alert has the email message body configured
                    Email address where the alert will be sent if the alert has this configured
# Recipient -
# Certificate - For internal use only
  SendEmail -
                    Boolean (true/false) indicating if Keyfactor Command is planning on sending an
email
                    for this certificate / recipient combination
# FirstRecipient - Boolean (true/false) indicating if this extension invocation is the first recip-
ient
#
                    for a given certificate
                    This can be used in the event it is desired to execute some logic once per certi-
ficate
                    This field applies only to expiration alerts
[hashtable]$context
# Four of the built-in context fields can be modified and used as output fields to change how (and
if)
# Keyfactor Command will send emails related to the alert being processed:
# Subject - If an email is produced this new value will be used to create the email subject.
# Message - If an email is produced this new value will be used to create the email message body.
```

```
Recipient - If an email is produced this new value will be used as the email recipient.
   SendEmail - This value can be used to override whether an email will be sent.
#
     A value of "true" will cause an email to be sent, while "false" will cause the associated email
#
     to not be sent.
     Examples:
        $context["Subject"] = "new subject line"
        $context["Message"] = "new message line"
#
        $context["Recipient"] = "newRecipient@keyexample.com"
        $context["SendEmail"] = "false"
# Typically output values would be used with some form of logic. As an example, to change the recip-
# of the email based on a metadata field provided to the handler, uncomment the following, provide
# appropriate values (including a metadata field that's being passed in to the handler in place of
# "SampleMetadataField"), and remove Recipient from ignoreKeys:
#
       if ($context["SampleMetadataField"] -eq "SomeValue") {
               $context["Recipient"] = "newRecipient@keyexample.com"
               }
# This example will output to a file the $context values for the user configured fields and skip the
# supplied ones. To output the system supplied fields, remove the desired items from the $ignoreKeys
array.
$ignoreKeys = "Subject", "Message", "SendEmail", "Certificate", "FirstRecipient", "Recipient"
# Path to the output file
$outputFile = ("C:\PSScripts\Output\SampleScriptOutput" + (get-date -UFormat "%Y%m%d%H%M") + ".txt")
# Add a comment and the date at the start of each output block
Add-Content -Path $outputFile -Value "Starting Output: $(Get-Date -format G)"
# Loop through all passed in key/value keys and process
$context.GetEnumerator() | % {
       if (-not $ignoreKeys.Contains($_.key)) {
               Add-Content -Path $outputFile -Value ($_.key + ": " + $_.value)
       }
}
# Add a blank line between output blocks
Add-Content -Path $outputFile -Value ""
```

### Adding PowerShell Handlers to Alerts

To add a PowerShell handler to an alert, the alert must first be created and saved. See <u>Alerts on page 166</u> for more information on creating various alerts. The example below uses an expiration alert, but the process applies to all types of alerts.

Next, you must create the PowerShell script and import it into Keyfactor Command. See <u>PowerShell</u> Scripts on page 219 for important information regarding working with scripts.

**Note:** See <u>PowerShell Scripts on page 219</u> for important information regarding working with scripts.

- 1. Select the alert to which you want to add the event handler from the respective alert grid.
- 2. Check the Use handler box and select the PowerShell event handler in the dropdown.

Figure 147: Use PowerShell Expiration Event Handler

**Tip:** If the expected event handler types do not appear, confirm that they exist and are enabled on the Event Handler Registration page (see <u>Event Handler Registration on page 741</u>).

3. Click the **Configure** button in the Use handler section of the page to open the Configure Event Handler dialog and then click **Add**.

Figure 148: Expiration Alert with PowerShell Event Handler

- 4. In the Configure Event Handler Parameters dialog, select **PowerShell Script Name** as the parameter Type. The Parameter Name field will change to *ScriptName*. Select the desired script from the dropdown, Only scripts that are configured for the selected alert category and imported to the Keyfactor Command database will display in the dropdown. See <a href="PowerShell Scripts on page 219">PowerShell Scripts on page 219</a> for more information on script handling.
- 5. Click **Save** to save your first parameter.

6. If desired, you can pass one or more parameters into your PowerShell script—either fixed text (type Static Value) or substitutable special text (type Special Text). To pass in fixed text, enter a name for the parameter (e.g. MyName), select the **Static Value** radio button, and type your fixed text in the Value field. To pass in special text, enter a name for the parameter (e.g. MyOther-Name), select the **Special Text** radio button, and select your desired substitutable special text field in the Value dropdown. When referring to these parameters in your PowerShell script, refer to them using a *\$context* hashtable parameter passed to the script, whose keys are the names entered in the event handler configuration. See <a href="Figure 149: PowerShell Event Handler with Multiple Parameters">Figure 149: PowerShell Event Handler with Multiple Parameters</a>. For example, for the parameter named "cn" in the event handler configuration, you might use this line in a PowerShell script:

```
if ($context.ContainsKey("cn")) { Add-Content -Path "C:\Stuff\MyOutput.txt" -
Value $context["cn"] }
```

In addition to the parameters you opt to pass in the event handler configuration, there are several built-in parameters that are always passed. These can be found in <u>Table 10: PowerShell Event Handler Special Fields</u>. You can reference these in your PowerShell script without having to specify them in your event handler configuration.

Figure 149: PowerShell Event Handler with Multiple Parameters

7. Click **Close** to return to the alert configuration and then save the alert.

Table 10: PowerShell Event Handler Special Fields

Name	Alert Type	Description
SendEmail	All	If true, email messages are sent in addition to processing of the Power-Shell script.
Subject	All	The full subject line of the alert.
Message	All	The full message body of the alert.
Recipient	All	The recipient of the alert. Alerts configured with more than one recipient will execute the PowerShell script multiple times—once for each recipient and each certificate or request.
Certificate	Expiration Only	For internal Keyfactor use only.
First Recip- ient	Expiration Only	If true and the alert has multiple recipients configured, this output is for the first recipient for the given certificate. Subsequent output for the same certificate and different recipients will show false for this value.

## Adding Logging Handlers to Alerts

To add a logging handler to an alert:

- 1. Edit an existing alert or create a new one. An alert cannot both send emails and write to the event log, so if you need to do both of these for the same alert configuration, you will need two separate alerts.
- Configure the message body as you would for an email message, including substitutable special
  text. The text from the message body is written to the event log. Note that HTML is not
  supported in the message body for event logging. The contents of the Subject line do not appear
  in the event log.
- 3. Check the Use handler box and select the logger event handler in the dropdown.

Figure 150: Expiration Alert with Event Logging Event Handler

**Tip:** If the expected event handler types do not appear, confirm that they exist and are enabled on the Event Handler Registration page (see <a href="Event Handler Registration on page 741">Event Handler Registration on page 741</a>).

4. Click the **Configure** button in the Use handler section of the page to open the Configure Event Handler dialog and then click **Add**.

Figure 151: Expiration Alert with Logging Event Handler

5. In the Configure Event Handler Parameter dialog, select **Logging Target Machine** as the parameter Type, and enter the fully qualified domain name of the server to which you wish to send the event log message in the Value field.

By default, the service accounts under which the Keyfactor Command application pool and Keyfactor Command service run have sufficient permissions to write to the event log on the Keyfactor Command server. If your target computer is not the Keyfactor Command server, you will need to grant appropriate permissions on that computer to one or both of these service accounts in order to write to the event log on that computer. When alerts containing event handlers are run in test most, the application pool service account is used. When alerts containing event handlers are run as a scheduled task, the Keyfactor Command service account is used. Local administrator permissions are needed initially to allow the service account to create the event log source types on the target machine. After that has been completed (on the first successful write of event logs to the server), permissions for the service account can be dialed back to "Generate security audits" or "Manage auditing and security log" in the local security policy.

If you wish to use a DNS alias for the target machine value, you may need to disable loopback checking on the Keyfactor Command server and reference the target machine. See <u>Disable</u> Loopback Checking on page 831.

- 6. Click **Save** to save and then **Close** to return to the alert configuration. No other parameters are needed (or functional) for an event logging event handler.
- 7. Test the alert as described in Expiration Alerts on page 167. It is not necessary to check the **Send Alerts** box during the test. Alerts are written to the Application event log.

Figure 152: Expiration Alert Event Log

## Adding Renewal Handlers to Expiration Alerts

**Important**: Renewal alerts will not function until you configure security permissions for the renewal handler as per *Configure Renewal Handler Permission* in the *Keyfactor Command Server Installation Guide*.

To add a renewal handler to an expiration alert:

- 1. Edit an existing expiration alert or create a new one. See Expiration Alert Operations on page 167.
- 2. Check the **Use handler** box and select the renewal event handler in the dropdown.

Figure 153: Use Renewal Event Handler on Expiration Alert

**Tip:** If the expected event handler types do not appear, confirm that they exist and are enabled on the Event Handler Registration page (see <u>Event Handler Registration on page 741</u>).

3. Click the **Configure** button in the Use handler section of the page to open the Configure Event Handler dialog and then click **Add**.

Figure 154: Expiration Alert with URL Event Handler

- 4. In the Configure Event Handler Parameter dialog, select **Renewal URL** as the parameter Type, and enter the URL to the Keyfactor Command server hosting the Keyfactor API component followed by /KeyfactorApi in the Value field. Click **Save** to save your first parameter.
- 5. If desired, you can configure a renewal template and CA for use with the renewal event handler. These settings are optional. If you don't set these, the renewal will be done using the template and CA originally used on the certificate. If you set only one of these—for example, the template—it will use the setting from the renewal event handler for that and retrieve the other—for example, the CA—from the certificate.
- 6. Test the alert as described in Expiration Alerts on page 167. It is not necessary to check the **Send Alerts** box during the test.

**Important**: Renewals **are** processed and new certificates **are issued** during expiration alert tests with associated renewal handlers.

## 2.1.7 Workflow

The options available in the Workflow section of the Management Portal are:

#### Workflow Definitions

Create workflows that manage certificate enrollments, renewals, or revocations end-to-end to require approvals, send emails, run PowerShell scripts and/or execute API requests as part of the process and workflows that are initiated by an automated task that runs periodically (every 10 minutes by default) to identify additions and removals of certificates from a specified certificate collection.

#### Workflow Instances

Manage initiated instances of workflows to view active, suspended (requiring approval) and completed enrollments, renewals, revocations, and additions and removals of certificates from a specified certificate collection. This page allows you to view the steps in a given instance of a workflow (which may be different from the current configuration of the workflow definition), restart failed workflow instances, and delete workflow instances.

## · My Workflows

Review initiated instances of workflows awaiting action by you and take action (e.g. approve or deny enrollment or revocation requests) or created by you.

#### 2.1.7.1 Workflow Definitions

The workflow builder in Keyfactor Command allows you to easily automate event-driven tasks to manage certificate enrollments, renewals, revocations on a per template basis. It can also monitor certificate collections on a periodic basis for certificates that change membership status based on the query criteria of a specified certificate collection. The workflows can be configured with multiple steps between the start and end of the operation that offer a simple way to configure notifications, approvals, and end-to-end automation throughout the environment. This provides for operational agility in an intuitive and easy-to-configure manner.

When a user begins one of the types of actions managed with workflow in Keyfactor Command on the usual Management Portal page (e.g. PFX Enrollment) or using the Keyfactor API or a certificate collection membership change is detected by an automated task, the workflow kicks in behind the scenes and executes however many steps have been configured in the workflow definition to bring the action to the appropriate conclusion along the desired path.

See <u>Certificate Collection Manager on page 85</u> for more information about creating certificate collections.

#### **Workflow Types**

The following types of workflow triggering events are supported:

#### Certificate Entered Collection

The workflow is initiated by an automated task that Keyfactor Command runs periodically against your collections to identify certificates that now meet the query criteria of the specified certificate collection.

For example, when a certificate discovered on an SSL scan becomes part of the Weak Keys collection, an email message can be generated notifying the PKI administrators that a new certificate with a weak key has been discovered.

#### Certificate Left Collection

The workflow is initiated by an automated task that Keyfactor Command runs periodically against your collections to identify certificates that no longer meet the query criteria of the specified certificate collection.

For example, when a certificate in the Web Server Certificates collection disappears, a REST request can be made to open a support ticket request to investigate the removal of a web server certificate.

#### Enrollment (Including Renewals)

The workflow is initiated by enrollment for a new or renewed certificate. Steps during the workflow can be used to do things such as require manager approval for the enrollment or manipulate the subject and/or SANs for the certificate request.

#### Revocation

The workflow is initiated by revoking a certificate. Steps during the workflow can be configured to do things such as modify the revocation comment entered when the certificate is revoked, append an additional comment, and store the resulting extended comment in a metadata field.

#### **Workflow Steps**

The following customizable workflow steps are supported within the workflows:

#### Send Email

Send an email message. This is a separate email message from those typically sent as part of a *Require Approval* step. You might send an email message as part of an enrollment request to notify approvers that a new request needs approval. The email messages can be customized to provide detailed information about, for example, the certificate request.

## Set Variable Data

Run PowerShell commands within the confines of the workflow to populate variables with information to pass back to the workflow. The PowerShell script contents are embedded within the step. This step does not call out to an external file. This provides a high level of security by greatly limiting the number of standard PowerShell cmdlets that can be executed by the workflow step. A small number of PowerShell cmdlets have been white listed to allow them to be included in workflow steps of this type, including:

- ° ConvertFrom-Csv
- ConvertFrom-Json
- ConvertFrom-Markdown
- ConvertFrom-SddlString
- ConvertFrom-StringData
- ConvertTo-Csv

- ConvertTo-Html
- ConvertTo-Json
- ConvertTo-Xml
- o ForEach-Object
- Get-Command
- Where-Object

#### Use Custom PowerShell

Run a PowerShell script that has been imported into the Keyfactor Command database. All scripts in the database that have been configured with the workflow category will be available for use. See *Extension/Scripts* in the *Keyfactor API Reference Guide* for adding scripts to the database.

#### Require Approval

Require approval for a workflow step before the step can be completed. The require approval step can require approval from just one approver or multiple approvers. The workflow will be suspended at this point until the correct number of approvals from users with the correct security roles is received or until one deny is received before continuing to the next step. As part of this step, an email message is sent indicating whether the step was approved or denied—typically to the requester. This step does not include logic to send an email initiating the approval process (letting users know something needs approval). Use a *Send Email* type step for this.

**Important:** Workflows are not supported with CA delegation when they contain steps that require approval. For more information, see the CA configuration *Authorization Methods Tab* in the *Keyfactor Command Reference Guide*.

**Note**: The users that you send email to initiating the approval process must be members of a security role that is allowed to submit signals (approve/deny) for the workflow in order to approve or deny the request.

**Tip:** The workflow builder does not include a step to send a notification to the requester of a certificate on an enrollment once the certificate is issued by the CA (as opposed to approved in Keyfactor Command). Use the issued alerts for this (see *Issued Request Alert Operations* in the *Keyfactor Command Reference Guide*).

## Invoke REST Request

Run a REST (API) request using Active Directory as an identity provider and Basic or Windows authentication. The REST request contents are embedded within the step. It does not call out to an external file.

## Invoke REST Request with OAuth

Run a REST (API) request using Keyfactor Identity Provider as an identity provider and Token authentication. The REST request contents are embedded within the step. It does not call out to an external file.

#### Update Certificate Request Subject\SANS for MSFT CAs (Enrollment Only)

On an enrollment (either CSR or PFX), create a resigned CSR to prepare an updated enrollment request for delivery to a Microsoft CA after a previous step in the workflow has been used to update either the SANs in the initial request, subject (DN) in the initial request or both. This step must be placed later in the workflow than the step(s) to modify the SANs and/or subject. The SANs and subject may be modified with either of the PowerShell step types or a custom step type. The step creates a new CSR using the same public key as the original CSR using the updated SAN and/or subject values. It signs the new CSR with the certificate provided in the step's configuration.

For this type of step you will need an enrollment agent certificate available as a PKCS#12 (.PFX) file with included private key to import into Keyfactor Command. This can be a user certificate or a computer certificate (e.g. generated from a copy of the *Enrollment Agent* template or the *Enrollment Agent* (*Computer*) template) and must have a Certificate Request Agent EKU. Note that the built-in *Enrollment Agent* and *Enrollment Agent* (*Computer*) templates do not allow private keys to be exported by default. You will need a template that allows private key export or will need to manually override private key export to create a certificate with an exportable private key in order to create a PKCS#12 (.PFX) file.

**Important**: This step applies to Microsoft CAs only. If this step is added to workflow for requests directed to an EJBCA CA, it will fail on enrollment. Note that EJBCA supports submission of updated SAN or subject details as part of standard functionality.

#### Windows Enrollment Gateway - Populate from AD (Enrollment Only)

On an enrollment done through the Keyfactor Windows Enrollment Gateway using a client-side template configured with the *Build from this Active Directory information* option on the template, this workflow step handles formatting the incoming subject, SANs, and/or SID in the certificate request appropriately such that the enrollment will complete successfully with the target CA and Keyfactor Command template, which is not configured to build from AD. Any Keyfactor Windows Enrollment Gateway using a client-side template configured with the subject as *Build from this Active Directory information* must be configured with a workflow step of this type on the Keyfactor Command template that has been mapped in the gateway to that template in order to complete an enrollment through the gateway. There are no configuration parameters for the step.

**Important**: The template in Keyfactor Command that is mapped to the client-side template configured to build the subject from Active Directory also needs to be configured with three enrollment fields to support handling the incoming subject, SANs, and/or SID. For more information about configuring this, see the *Keyfactor Windows Enrollment Gateway Installation and Configuration Guide*.

In addition to these customizable types of steps, there are built-in steps that you won't see unless you're using the Keyfactor API to view or edit the workflows (see *Workflow Definitions* in the

Keyfactor API Reference Guide). At the end of their respective workflow types there are an enroll step and a revoke step to initiate the actual enrollment or revocation if the workflow reaches the end without being denied or failing. These built-in steps cannot be modified or moved to a different location in the workflow. There are also NOOP steps that indicate the start and end of the workflow for housekeeping purposes.

There are two types of workflow definition:

#### Global

The global workflow definitions are built into the product and cannot be deleted, though they can be modified to add workflow steps, if desired. Global workflow definitions do not have a specific associated *key*—in the case of the currently available workflows, this is a certificate template—and apply to all requests of the workflow's type (e.g. enrollment) that are not otherwise handled by a custom workflow specifying a *key*.

#### Custom

Custom workflow definitions are any additional workflow definitions you define beyond the built-in ones. Custom workflows are associated with a specific *key* (certificate template or certificate collection) and each workflow only applies to requests made using that *key*.

**Note:** All certificate enrollment, renewal, and revocation requests go through workflow even if you haven't created any workflow steps or added any custom workflow definitions. In the absence of customization, the global workflow definitions are used. The addition and removal of certificates from certificate collections only go through workflow if you create custom workflows for them.

Figure 155: Workflow Definitions

When requiring approval for enrollment using workflow definitions in Keyfactor Command, templates do not need to be configured to require manager approval at the CA level in the certificate template. This is because the approval handling is fully controlled within Keyfactor Command. In fact, templates generally should not be configured to require CA manager approval when using Keyfactor Command workflow, since this would generally require approval both at the Keyfactor Command level and at the CA level.

Tip: Click the help icon (3) next to the page title to open the embedded web copy of the Keyfactor Command Documentation Suite to this section.

You can also find the help icon at the top of the page next to the Log Out button. From here you can choose to open either the Keyfactor Command Documentation Suite at the home page or the Keyfactor API Endpoint Utility.

## **Workflow Definition Operations**

The workflow builder in Keyfactor Command is a powerful feature that allows you to manage certificate enrollments, renewals, and revocations on a per template basis, end-to-end. It can also monitor certificate collections on a periodic basis for certificates that change membership status based on the query criteria of a specified certificate collection. Out of the box, there are workflow builder steps such as requiring approvals for actions like certificate enrollment and revocation requests, sending email notifications, and running PowerShell scripts and API requests as part of the request flow.

Tip: There are two built-in workflow definitions—Global Enrollment Workflow and Global Revocation Workflow-that are used to manage enrollment and revocation requests which are not otherwise handled by custom workflows. These workflows can be configured with steps (see Adding, Copying or Modifying a Workflow Definition on page 237), but they cannot be deleted. There are no built-in workflow definitions for the addition and removal of certificates from certificate collections. These actions only go through workflow if you create custom workflows for them.

# Working with the Keyfactor Command Workflow Builder Workspace

The workflow builder workspace is laid out with the workflow steps running from top to bottom in the middle (initially), the Workflow Definition dialog in a collapsible window on the right, and workspace controls at the bottom left. If you create several steps in a workflow or are working on a smaller browser screen, you may have more workflow steps than will fit in the configuration window. To navigate around the workspace and personalize it:

- · Click and drag the workspace background to move the steps around the workspace. In this way you can reach steps at the top or bottom of the workflow that do not initially appear.
- Click the open button (←) to open the Workflow Definition dialog and the close button (→) to close the Workflow Definition dialog.
- Click the plus button with a circle around it (+) to add a new workflow step at that point in the workflow.
- Click the plus button in the lower left of the workspace (+) to zoom in on the steps.
- Click the minus button in the lower left of the workspace (-) to zoom out on the steps.
- Click the auto size button in the lower left of the workspace (3) to recenter and fit the steps to the window.

## Workflow Configuration

Use the editor to add or remove steps. Click on a step to edit the necessary properties.

Figure 156: Using the Workflow Workspace

**Tip:** At any point while editing your workflow definition, you can click **Undo** at the bottom of the Add/Edit Workflow Definition dialog to undo changes made since the last save to the current workflow step you are editing or **Undo All** at the top of the workflow builder workspace to undo all changes made to the workflow definition since the last save.

**Tip:** To open a pop-out dialog with more real-estate for editing content in large text areas, like scripts and email messages:

- Navigate to the field you want to edit on the workflow definition.
- . Click at the top right above the large text field.
- An *Edit Content* or *Edit PowerShell* window will open to accept your input. The *Edit Content* window supports token replacement. The *Edit PowerShell* window will open with a text editor. Enter your information.
- Click X at the top right to close the edit window and return to the workflow definition, populated with your text.

Figure 157: Edit PowerShell Window

# Adding, Copying or Modifying a Workflow Definition

**Tip**: The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Workflows > Definitions > Read Workflows > Definitions > Modify

To add a new workflow definition or modify an existing one:

- 1. In the Management Portal, browse to Workflow > Workflow Definitions.
- 2. On the Workflow Definitions page, click **Add** from the top menu to create a new blank workflow definition, **Copy** from either the top or right click menu to copy an existing workflow to create a new one, or **Edit** from either the top or right click menu, to modify an existing one. This will open the workflow in the workflow builder workspace with the Workflow Definition dialog open on the right.

**Note**: When you create a new workflow definition by copying an existing one, the word *copy* will be appended to the end of the definition name and the workflow key (template or certificate collection) will be cleared. Other data from the copied workflow will be retained.

3. In the Add/Edit Workflow Definition dialog on the Definition tab, enter a Name for your workflow.

Figure 159: Create a New Workflow Definition

- 4. In the **Description** field, enter a description for the workflow definition.
- 5. In the **Type** dropdown, select the type of requests this workflow will handle. See <u>Workflow Types</u> on page 230 for a description of each workflow type.

- 6. Once you have selected a type, a key field will appear.
  - If you selected a type of Enrollment or Revocation, the key field is **Template**.
  - If you selected a type of Certificate Entered Collection or Certificate Left Collection, the key field is **Certificate Collection**.

Begin typing in the **Template** or **Certificate Collection** field to search for available templates or certificate collections or click in the field and scroll down to locate your desired template or certificate collection. Templates that have been configured with a template friendly name will appear by friendly name.

Note: The key cannot be changed on an edit.

7. On the Workflow Configuration page, click the plus button in between two workflow steps where you want to add a new step. A new step box will be added below the plus that you clicked.

Figure 160: Click Plus to Add a New Workflow Definition Step

**Tip:** To delete a step, click the X at the top right of the step box and confirm that you want to delete the step.

- 8. Click the new step box to load the step in the Add/Edit Workflow Definition dialog. If the dialog is not already open, clicking a step will open it, or you can open a step by clicking the open button (

  and then clicking the desired step to load it into the dialog.
- 9. In the Add/Edit Workflow Definition dialog on the Step tab in the General section, select a **Step Type** for the step in the dropdown. To narrow the list of step types in the dropdown, begin typing a search string in the Search field. See <a href="Workflow Steps on page 231">Workflow Steps on page 231</a> for a description of each step type.

Figure 161: Select a Workflow Definition Step

**Note**: On an edit, if you change the workflow step type, you must also change the **Unique Name**. Changing the workflow step type without changing the unique name will result in an error similar to the following:

System.Collections.Generic.KeyNotFoundException: The given key was not present in the dictionary

Instead of changing both the workflow step type and unique name, you may be prefer to delete the step and create a new step of the desired type.

In the Add/Edit Workflow Definition dialog on the Step tab in the General section, enter a
 Display Name for the step. This name appears as the title of the step box on the workflow work-space page.

Figure 162: Display Name is Step Name Title

- 11. In the Add/Edit Workflow Definition dialog on the Step tab in the General section, either accept the automatically generated **Unique Name** for the step or modify it. This name must be unique among the steps within the particular workflow. It is intended to be used as a user-friendly reference ID.
- 12. In the Add/Edit Workflow Definition dialog on the Step tab in the Workflow Step Execution Conditions section, click the **Workflow Step Enabled** toggle to enable or disable the workflow. It is enabled by default.
- 13. Workflow Step Execution Conditions

In the Workflow Step Execution Conditions section, click **Add** in the Optional Workflow Step Conditions for Execution section to create a new condition for the step. Conditions are true/false statements indicating whether the step should run and can be based on tokens. See <u>Workflow Step Execution Conditions on page 249</u> for in-depth information and examples of workflow step conditions.

#### 14. Configuration Parameters

The fields in the Configuration Parameters section will vary depending on the type of step you're configuring. See <u>Workflow Definitions Configuration Parameters on page 251</u> for in-depth information and examples of each configuration parameter option.

15. For Require Approval steps or custom steps requiring signals, in the Workflow Step Editor in the Signals section, select one or more security roles (see <u>Security Roles and Claims on page 623</u>) in the **Approval Status** dropdown. To narrow the list of security roles in the dropdown, begin typing a search string in the Search field. Click the erase icon (♠2) to clear your selections.

Users who hold the security role(s) selected here will be able to submit signals (e.g. approve requests) for this workflow.

**Tip:** Signals represent data used at the point in the workflow step where the workflow needs to continue based on user input. Here, you're configuring which users are allowed to provide that input.

Figure 163: Signals Configuration for a Requires Approval Workflow Definition Step

**Important:** If all the security roles configured for a workflow step are deleted from Keyfactor Command, no users will be able to submit signals for workflow instances initiated with that workflow definition. To remedy this, update the workflow definition with one or more current security roles, re-publish it, and then restart any outstanding workflow instances.

- 16. Click Save Workflow at the top of the workflow workspace to save the workflow step.
- 17. On the Workflow Configuration page, click the plus button in between two workflow steps to add another step in the workflow or click **Save Workflow** to save the workflow with its current steps.
- 18. Before you can use the workflow, it must be published to activate it. Click the **Publish** button at the top of the workflow workspace to publish it immediately or return to the workflow definitions page and publish it later, if desired (see Publishing a Workflow Definition on the next page).

Tip: Clicking Publish automatically saves the workflow.

19. To close the workflow workspace and return to the workflow definitions page, click the **Close** button at the top of the workflow workspace.

**Note**: If you edit an existing *published* workflow definition, a new version of the workflow definition will be created. If you edit an existing workflow definition which has *never been published*, the existing configuration will be overwritten with the changes you've made—a new version will not be created.

An audit log entry is created when you add or edit a workflow definition (see Audit Log on page 718).

## **Deleting a Workflow Definition**

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Workflows > Definitions > Read Workflows > Definitions > Modify

To delete a workflow definition:

- 1. In the Management Portal, browse to Workflow > Workflow Definitions.
- 2. On the Workflow Definitions page, select a workflow definition and click **Delete** from either the top or right-click menu.
- 3. On the Confirm Operation alert, click **OK** to confirm or **Cancel** to cancel the operation.

**Note**: The built-in global workflow definitions (*Global Revocation Workflow* and *Global Enrollment Workflow*) cannot be deleted. A workflow definition cannot be deleted if there is an active or suspended workflow instance for the workflow definition.

An audit log entry is created when you delete a workflow definition (see Audit Log on page 718).

## **Publishing a Workflow Definition**

Workflow definitions are drafts that cannot be actively used until you take the step to publish them. This allows you to add new workflows or update existing ones without interrupting the flow of current activity. Then, once the workflow definition is complete and ready for use, you can activate it. This can be done on the workflow workspace page while editing the workflow (see <a href="Adding, Copying or Modifying a Workflow Definition on page 237">Adding, Copying or Modifying a Workflow Definition on page 237</a>) or from the workflow definitions page.

**Tip**: The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Workflows > Definitions > Read Workflows > Definitions > Modify

To publish a workflow definition from the workflow definitions page:

- 1. In the Management Portal, browse to Workflow > Workflow Definitions.
- 2. On the Workflow Definitions page, select a workflow definition and click **Publish** from either the top or right-click menu.
- 3. On the Confirm Operation alert, click **OK** to confirm or **Cancel** to cancel the operation.

Alternately, publish a workflow definition from the workflow builder workspace:

- 1. In the Management Portal, browse to Workflow > Workflow Definitions.
- 2. On the Workflow Definitions page, select a workflow definition to open the workflow definition you wish to publish.
- 3. Click the **Publish** button at the top of the workflow workspace to publish it.

## **Exporting a Workflow**

Workflow definitions can be exported either from the workflow workspace page while viewing or editing the workflow (see <u>Adding, Copying or Modifying a Workflow Definition on page 237</u>) or from the workflow definitions page.

- Export a workflow for backup purposes.
- Export a workflow that you've fully configured and which you need to replicate and then import under another name to create a duplicate of it.
- Export a previous version of a workflow and import it as the current version to revert to using the previous version.

Tip: The following permissions (see Security Roles and Claims in the Keyfactor Command Reference Guide) are required to use this feature: Workflows > Definitions > Read

To export a workflow definition from the workflow workspace:

- 1. In the Management Portal, browse to Workflow > Workflow Definitions.
- 2. On the Workflow Definitions page, click Edit from either the top or right click menu. This will open the workflow in the workflow workspace with the Workflow Definition dialog open on the right.
- 3. At the top of the workflow workspace, select a different Version of the workflow in the dropdown, if desired (see Workflow Versions on page 248).
- 4. At the top of the workflow workspace, click **Export**.
- 5. Browse to place the exported file on the local computer. The file will have an extension of .json.

To export a workflow definition from the workflow definitions page:

- 1. In the Management Portal, browse to Workflow > Workflow Definitions.
- 2. On the Workflow Definitions page, select a workflow definition and click Export from either the top or right-click menu.
- 3. In the Export Workflow Definition dialog, select a Version and click Export.

Figure 164: Export Workflow Definition

4. Browse to place the exported file on the local computer. The file will have an extension of .json.

**Note**: The following information is removed on export and will not be in the exported file:

#### Secrets

Some types of workflow steps include secret values (e.g. passwords). Secret values are not exported. If your workflow includes steps with secret values, these will need to be reentered if you choose to import the exported file.

#### Roles for Signals

Some types of workflow steps make use of signals to allow users to provide input to the workflow midstream (e.g. provide approvals). This requires configuration of security roles that define who is allowed to provide this input. These security role values are not exported. You will need to set appropriate security roles on any workflow steps that use signals if you choose to import the exported file.

## Importing a Workflow

Workflow definitions can be imported either to create a new workflow or to replace an existing workflow (e.g. to revert to a backup). When you import a workflow definition while editing an existing workflow definition, it will overwrite any changes you have made to the existing workflow since the last time it was published. Previously published versions of the workflow—including the most recent—will be retained. This is useful in cases where you want to export a previous version of a workflow and reimport it to make it the currently active version. This can be used to import a new workflow customized for you by the Keyfactor team.

**Tip**: The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Workflows > Definitions > Read Workflows > Definitions > Modify

To import a workflow definition:

- 1. In the Management Portal, browse to Workflow > Workflow Definitions.
- 2. On the Workflow Definitions page, click Add from the top menu to create a new workflow definition into which you will import, or Edit from either the top or right click menu, to import into an existing one to revert to a previous version. This will open the workflow in the workflow workspace with the Workflow Definition dialog open on the right.
- 3. At the top of the workflow workspace, click Import.
- 4. Browse to locate the workflow definition file you wish to import. Only files with an extension of *.json* will appear.

Figure 165: Browse to Locate a Workflow Definition to Import

**Tip:** In order to be successfully imported, the file must be correctly formatted JSON with at least *WorkflowType* and *Steps* properties. The maximum file upload size is 2 MB.

- 5. Click **Import** to import the workflow definition and populate it into the workflow workspace.
- 6. On the Confirm Operation alert, click **OK** to confirm or **Cancel** to cancel the operation.
- 7. In the workflow workspace, edit and save the workflow definition as needed as per Adding, Copying or Modifying a Workflow Definition on page 237. The following values will need attention:

#### Key (Template or Certificate Collection)

When the workflow definition is imported into a new workflow definition, the key is cleared. You will need to set an appropriate key (template for enrollment or revocation type workflows, certificate collection for workflows of type certificate entered or left collection) on the imported workflow definition before saving. The key is not cleared for imports into workflows with existing published versions.

This is done both to support export of workflow definitions from one environment and import into another where the key set likely would be different and to support copying of workflow definitions, since you can't have two definitions for the same key.

#### Secrets

Some types of workflow steps include secret values (e.g. passwords). Secret values are not imported. If your workflow includes steps with secret values, these will need to be reentered. This is true for imports into new workflow definitions and workflow definitions with existing published versions.

#### Roles for Signals

Some types of workflow steps make use of signals to allow users to provide input to the workflow midstream (e.g. provide approvals). This requires configuration of security roles that define who is allowed to provide this input. These security role values are not imported. You will need to set appropriate security roles on any workflow steps that use signals before saving. This is true for imports into new workflow definitions and workflow definitions with existing published versions.

This is done to support export of workflow definitions from one environment and import into another where the security role set likely would be different.

**Important:** If you're importing a copy of a workflow definition that already exists in Keyfactor Command and you want to save it as a separate copy, be sure to change the **Name** of the workflow before saving the imported workflow to avoid overwriting the existing version of the workflow.

#### **Workflow Versions**

When you open a workflow definition for editing, you will see the version of the workflow shown at the upper left of the workflow workspace in a dropdown. By default, the current version will be shown.

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Workflows > Definitions > Read

# Workflow Configuration

Use the editor to add or remove steps. Click on a step to edit the necessary properties.

Figure 166: Workflow Definition Versions: View Current Version

When you have the current, most recent, version of the workflow loaded, you will see several options in the button bar at the top of the workflow workspace (if you have appropriate permissions) and the Add/Edit Workflow Definition Dialog will be active. If you select an older version in the dropdown, only the Version, Export, and Close options will appear on the workflow workspace button bar and the Add/Edit Workflow Definition Dialog will be read only.

# Workflow Configuration

Use the editor to add or remove steps. Click on a step to edit the necessary properties.

Figure 167: Workflow Definition Versions: View Previous Version

This option is designed to allow you to review previous versions of a workflow or export them as backups or to be re-imported to be used as a base for generating new workflows.

#### **Workflow Step Execution Conditions**

This section provides in-depth explanations and examples for using conditions in workflow definitions (see Workflow Step Execution Conditions on page 241).

Tip: Tokens (a.k.a. substitutable special text) may be used in the condition field. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can create a token in a PowerShell step that has a value of True or False based on something determined in the step and then evaluate that token in a subsequent require approval step to determine whether to execute the require approval step based on the results from the PowerShell step. Fields that support tokens are indicated with \$() at the top right of the field. To use a token in a field, begin typing at the location where you want the token to appear, starting with \$(. Once you have typed \$(, a second ) will appear automatically along with a dropdown of available tokens to choose from. You may continue typing to narrow the values in the dropdown (e.g. type \$(req to see only tokens that begin "req").

Figure 168: Tokens are Highlighted

To add a new condition, click Add and in the Condition Variable field enter either a static value of True or False or a token that will have a value of True or False at the time the step is run. More than one condition may be added. If multiple conditions are used in the same step, all conditions must have a value of True at the time the step is evaluated to be run in order for the step to run. If any single condition evaluates to False, the step will not run.

Set Variable Data and Require Approval with a Condition

The following example takes the common name entered during an enrollment and evaluates it to determine whether the domain name on it matches "keyexample.com" or not. If the domain is "keyexample.com", the enrollment is allowed to proceed without requiring approval. If the domain does not match "keyexample.com", the request requires approval. This example uses both a Power-Shell Set Variable Data step and a Require Approval step.

To do this, first create the PowerShell step. Here we use a *Set Variable Data* step (see <u>Set Variable Data</u> on page 276) since no functions need to be called outside the confines of Keyfactor Command,

though you could use a *Custom PowerShell Script* step instead. Add a Script Parameter to pull the request CN into the script.

Figure 169: Conditions Example: Add Parameters

In the Insert PowerShell Script field, enter a script similar to the following:

```
# Declare your parameter at the beginning
param(
   [string]$SubjectCN
# Initialize a variable for the response
$shouldRun = @()
# Check to see if the requested CN ends with keyexample.com and require approval in the next step if
it does not
$Suffix = "keyexample.com"
if ($SubjectCN.EndsWith($Suffix))
   $shouldRun = "False"
}else {
  $shouldRun = "True"
}
# Return the true/false value to the workflow as a hashtable
$result = @{ "shouldRun" = $shouldRun; }
return $result
```

Next, create the require approval request step (see Require Approval on page 264) with \$(shouldRun) as a condition like so:

Figure 170: Conditions Example: Add Conditions for Require Approval Step

This condition on the require approval step will cause the approvals configured in the step to be required only if the CN submitted in the request does not end with "keyexample.com", so a request for "CN=mycert.keyother.com" will require approval but a request for "CN=mycert.keyexample.com" will not.

## **Workflow Definitions Configuration Parameters**

This section provides in-depth explanations and examples for using configuration parameters in work-flow definitions (see <u>Configuration Parameters on page 241</u>). The configuration parameters vary depending on the type of workflow step. The below information is broken down by step type. Most steps have at least one example, though the examples may incorporate more than one step type. The following examples are provided:

- Set Variable Data and Require Approval with a Condition on page 249
- Invoke REST Request for Data Lookup on Enrollment on page 255
- Invoke REST Request and Set Variable Data with Variable Passing on page 261
- Set Variable Data for Revocation on page 278
- Set Variable Data for Enrollment on page 280
- Use Custom PowerShell for Enrollment on page 284
- Use Custom PowerShell and Require Approval on page 287
- Use Custom PowerShell with Embedded REST Request, Send Email, and Require Approval on page 267
- Update Certificate Request Subject\SANS for MSFT CAs on page 292

For an overview of the types of workflow steps, see Workflow Steps on page 231.

## **Invoke REST Request**

This step type is used only for Keyfactor Command implementations using Active Directory as an identity provider. If you're using Keyfactor Identity Provider, refer to the Invoke REST Request with OAuth step type (see Invoke REST Request with OAuth on page 258).

Tip: Tokens (a.k.a. substitutable special text) may be used in the URL and request content fields. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can take the revocation comment entered when the revocation request is approved—\$(cmnt) and insert it into a custom metadata field in the certificate by doing a PUT / Certificates/Metadata request for the \$(id). Fields that support tokens are indicated with SO at the top right of the field. To use a token in a field, begin typing at the location where you want the token to appear, starting with \$(. Once you have typed \$(, a second ) will appear automatically along with a dropdown of available tokens to choose from. You may continue typing to narrow the values in the dropdown (e.g. type \$(req to see only tokens that begin "req").

Figure 171: Tokens are Highlighted

Headers: Enter any headers needed for your request. For a Keyfactor API request, this might look like:

x-keyfactor-requested-with: APIClient x-keyfactor-api-version: 1

Tip: For a Keyfactor API request, version 1 is assumed if no version is specified. Content type and authorization headers do not need to be specified, since those are addressed elsewhere in the configuration.

Variable to Store Response in: Provide a name for the parameter in which to store the response data from your request. You can then reference this parameter from subsequent steps in the workflow.

Tip: The response is stored as a serialized JObject. To make use of only a portion of the response data in your subsequent step, use JSON path syntax. For example, say you returned the data from a GET /Agents request in a variable called MyResponse and you wanted to reference the ClientMachine name for the orchestrator in a subsequent email message. To limit the data to the first result (0) and only the ClientMachine name, in the email message you would enter the following:

\$(MyResponse.[0].ClientMachine)

Verb: In the dropdown, select the type of request you wish to make (e.g. GET, POST).

- Use Basic Authentication: Check this box to use Basic authentication for the request. If you do
  not check this box, Windows authentication in the context of the Keyfactor Command application
  pool user will be used (see Create Active Directory Service Accounts for Keyfactor Command in
  the Keyfactor Command Server Installation Guide).
- **Username** and **[Password]**: Enter the username and password to use for authentication if *Use Basic Authentication* is checked. In the Username and Password dialogs, the options are Load From Keyfactor Secrets or Load From PAM Provider.

A Keyfactor secret is a user-defined password or other information that is encrypted and stored securely in the Keyfactor Command database. Although Keyfactor recommends using Privileged Access Management (see <a href="Privileged Access Management (PAM)">Privileged Access Management (PAM)</a> on page 744) as a more secure solution to secure information, Keyfactor Secret is an option for customers that do not already have a relationship with a PAM provider such as CyberArk or Delinea.

**Important:** Keyfactor highly recommends that you use strong passwords for any accounts or certificates related to Keyfactor Command and associated products, especially when these have elevated or administrative access. A strong password has at least 12 characters (more is better) and multiple character classes (lowercase letters, uppercase letters, numeral, and symbols). Ideally, each password would be randomly generated. Avoid password re-use.

Select the **Load From Keyfactor Secrets** radio button as the *Secret Source* if you want Keyfactor Command to encrypt and store the password in the Keyfactor Command database. Enter and confirm a password.

Select the **Load from PAM Provider** radio button as the *Secret Source* if you want to store the password in a supported third-party PAM solution (see <u>Privileged Access Management (PAM) on page 744</u>). The remaining fields on the dialog will vary depending on the PAM provider. For example:

#### CyberArk

Select your CyberArk provider in the **Providers** dropdown if your PAM provider is CyberArk (see Adding or Modifying a PAM Provider on page 752). The remaining fields in the dialog will then be:

- ° Safe—The name of the safe the credential resides in.
- Object—The name of the username or password object in the safe.
- Folder—The path and name of the folder that stores the object (e.g. Root or Root\MyDir).

#### Delinea

Select your Delinea provider in the **Providers** dropdown if your PAM provider is Delinea (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining field in the dialog will then be:

- Secret Server Secret ID—The numeric ID of the secret to retrieve from Secret Server.
- Secret Field Name—The name of the field to use when retrieving a secret form Secret Server.

## Hashicorp

Select your Hashicorp Vault provider in the **Providers** dropdown if your PAM provider is Hashicorp Vault (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining field in the dialog will then be:

- KV Secret Key—The key of the secret to retrieve from the Hashicorp Vault.
- KV Secret Name—The name of the secret to retrieve from the Hashicorp Vault.
- **URL**: Enter the request URL for the request, including tokens if desired. For a Keyfactor API request, this might look like (with query parameters):

https://keyfactor.keyexample.com/KeyfactorAPI/Certificates?pq.queryString=CN%20-contains%20%22appsrvr14%22%20AND%20CertStorePath%20-ne%20NULL

Or, with tokens:

https://keyfactor.keyexample.com/KeyfactorAPI/Certificates/\$(certid)

**Note**: To prevent REST requests from being made to inappropriate locations by malicious users, configure a system environment variable of KEYFACTOR\_BLOCKED\_
OUTBOUND\_IPS on your Keyfactor Command server pointing to the IP address or range of addresses in CIDR format that you wish to block. Both IPv4 and IPv6 addresses are supported. More than one address or range may be specified in a comma-delimited list. For example:

```
192.168.12.0/24,192.168.14.22/24
```

When a REST request is made where the URL is either configured to a blocked IP address or resolves via DNS to a blocked IP address, the REST request will fail.

- Content-Type: In the dropdown, select the content type for the request:
  - application/json
- Request Content: The request body of the REST request, if required, with tokens, if desired. For a Keyfactor API request, this will vary depending on the request and might look like (for a PUT / Certificates/Metadata request):

```
{
    "Id": "$(certid)",
    "Metadata":{
```

```
"RevocationComment": "$(cmnt)"
}
```

**Note**: This example assumes you have a metadata field called *RevocationComment* (see Certificate Metadata on page 712).

For an example using a Keyfactor API endpoint within a PowerShell script, see <u>Use Custom Power-Shell with Embedded REST Request</u>, <u>Send Email</u>, <u>and Require Approval on page 267</u>. For an example using an Invoke REST Request and a PowerShell step passing data between them, see <u>Invoke REST Request</u> and Set Variable Data with Variable Passing on page 261.

Invoke REST Request for Data Lookup on Enrollment

The following example takes the requester for an enrollment request and uses that to look up some information about the requester's SSH user record. This example uses a PowerShell step, a REST Request step, and an email step to deliver the information about the SSH user.

To do this, first create the PowerShell step. Here we use a *Set Variable Data* step (see <u>Set Variable Data on page 276</u>) since no functions need to be called outside the confines of Keyfactor Command other than those that are supported within Set Variable Data, though you could use a *Custom Power-Shell Script* step instead. Add Script Parameters to pull the requester into the script (see <u>Figure 172</u>: Requester Lookup Example: Add Parameters).

Figure 172: Requester Lookup Example: Add Parameters

In the Insert PowerShell Script field, enter a script similar to the following:

```
# Declare your parameters at the beginning
param(
    [string]$Requester
)
#Convert the requester to JSON
```

```
$RequesterJSON = ($Requester | ConvertTo-Json)

# Build the query for the REST step
$Query = "Username -eq $RequesterJSON"

# Return the query to the workflow as a hashtable
$result = @{ "Query" = $Query }
return $result
```

Next, create the REST request step with the following values:

• **Headers**: The GET /SSH/Users method has a version 2 with additional features. To access version 2, this version must be specified in the header.

```
{
    "x-keyfactor-requested-with": [
        "APIClient"
],
    "x-keyfactor-api-version": [
        "2"
]
}
```

# Configuration Parameters Headers

Figure 173: Requester Lookup Example: Add Headers for REST Request

- Variable to Store Response in: MyResponse
- · Verb: GET
- **URL**: Note that the \$(Query) from the PowerShell step is provided in the URL (*keyfactor.keyexample.com* is your Keyfactor Command server name).

```
https://keyfactor.keyexample.com/KeyfactorAPI/SSH/Users?QueryString=$(Query)
```

- · Content-Type: application/json
- Request Content: None (The request is provided in the URL; there is no body for this endpoint.)

This REST step takes the Query built in the PowerShell step, containing the requester's username, and submits it to the GET /SSH/Users endpoint. The response contains all the information from the user's SSH key record.

Next, create the Send Email step. In the configuration parameters, give your email a Subject that will help highlight the information:

```
Certificate Enrollment Request for $(request:cn)
```

In the main Message of the email, provide the required information using tokens, including the information retrieved from the GET /SSH/Users endpoint (see <u>Substitutable Text Tokens for Workflow on page 296</u>):

```
Hello,
A certificate using the $(template) template was requested by $(requester:displayname) from $(CA) on
$(subdate).
The certificate details include:
  CN: $(request:cn)
     DN: $(request:dn)
     SANs: $(sans)
     App Owner First Name: $(metadata:AppOwnerFirstName)
     App Owner Last Name: $(metadata:AppOwnerLastName)
  The requester's SSH information includes:
  ID: $(MyResponse.Result[0].Key.Id)
     Email: $(MyResponse.Result[0].Key.Email)
     Comments: $(MyResponse.Result[0].Key.Comments.[*])
  Thanks!
Your Certificate Management Tool
```

**Note:** The \$(requester:displayname) substitutable special text token is only supported in environments using Active Directory as an identity provider.

In the Recipients, add all the email recipients who should receive this information.

**Note**: If your REST request takes a long time to complete, the step may time out and the workflow instance fail. The default timeout is 60 seconds and is configurable with the *Workflow Step Run Timeout* application setting (see Application Settings: Workflow Tab on page 622).

## Invoke REST Request with OAuth

This step type is used only for Keyfactor Command implementations using Keyfactor Identity Provider as an identity provider. If you're using Active Directory, refer to the Invoke REST Request step type (see Invoke REST Request on page 251).

Tip: Tokens (a.k.a. substitutable special text) may be used in the URL and request content fields. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can take the revocation comment entered when the revocation request is approved—\$(cmnt)— and insert it into a custom metadata field in the certificate by doing a PUT /Certificates/Metadata request for the \$(id). Fields that support tokens are indicated with \$0 at the top right of the field. To use a token in a field, begin typing at the location where you want the token to appear, starting with \$(. Once you have typed \$(, a second ) will appear automatically along with a dropdown of available tokens to choose from. You may continue typing to narrow the values in the dropdown (e.g. type \$(req to see only tokens that begin "req").

Figure 174: Tokens are Highlighted

 Headers: Enter any headers needed for your request. For a Keyfactor API request, this might look like:

x-keyfactor-requested-with: APIClient x-keyfactor-api-version: 1

**Tip:** For a Keyfactor API request, version 1 is assumed if no version is specified. Content type and authorization headers do not need to be specified, since those are addressed elsewhere in the configuration.

• Variable to Store Response in: Provide a name for the parameter in which to store the response data from your request. You can then reference this parameter from subsequent steps in the workflow.

**Tip:** The response is stored as a serialized JObject. To make use of only a portion of the response data in your subsequent step, use JSON path syntax. For example, say you returned the data from a GET /Agents request in a variable called *MyResponse* and you wanted to reference the *ClientMachine* name for the orchestrator in a subsequent email message. To limit the data to the first result (0) and only the ClientMachine name, in the email message you would enter the following:

\$(MyResponse.[0].ClientMachine)

- Verb: In the dropdown, select the type of request you wish to make (e.g. GET, POST).
- Client ID: Enter the ID of the Keyfactor Identity Provider client that should be used to authenticate the session (see *Create Service Accounts for the Keyfactor API* in the *Keyfactor API* Reference Guide).
- Client Secret: Click the Set\UpdateClient Secret button and in the Client Secret dialog, enter the secret for the Keyfactor Identity Provider client that should be used to authenticate the session. In the Client Secret dialog, the options are Load From Keyfactor Secrets or Load From PAM Provider.

A Keyfactor secret is a user-defined password or other information that is encrypted and stored securely in the Keyfactor Command database. Although Keyfactor recommends using Privileged Access Management (see <a href="Privileged Access Management (PAM)">Privileged Access Management (PAM)</a> on page 744) as a more secure solution to secure information, Keyfactor Secret is an option for customers that do not already have a relationship with a PAM provider such as CyberArk or Delinea.

Important: Keyfactor highly recommends that you use strong passwords for any accounts or certificates related to Keyfactor Command and associated products, especially when these have elevated or administrative access. A strong password has at least 12 characters (more is better) and multiple character classes (lowercase letters, uppercase letters, numeral, and symbols). Ideally, each password would be randomly generated. Avoid password re-use.

Select the **Load From Keyfactor Secrets** radio button as the *Secret Source* if you want Keyfactor Command to encrypt and store the password in the Keyfactor Command database. Enter and confirm a password.

Select the **Load from PAM Provider** radio button as the *Secret Source* if you want to store the password in a supported third-party PAM solution (see <u>Privileged Access Management (PAM) on page 744</u>). The remaining fields on the dialog will vary depending on the PAM provider. For example:

## **CyberArk**

Select your CyberArk provider in the **Providers** dropdown if your PAM provider is CyberArk (see Adding or Modifying a PAM Provider on page 752). The remaining fields in the dialog will then be:

- Safe—The name of the safe the credential resides in.
- Object—The name of the username or password object in the safe.
- Folder—The path and name of the folder that stores the object (e.g. Root or Root\MyDir).

#### Delinea

Select your Delinea provider in the **Providers** dropdown if your PAM provider is Delinea (see Adding or Modifying a PAM Provider on page 752). The remaining field in the dialog will then be:

- ° Secret Server Secret ID—The numeric ID of the secret to retrieve from Secret Server.
- Secret Field Name—The name of the field to use when retrieving a secret form Secret Server.

## Hashicorp

Select your Hashicorp Vault provider in the **Providers** dropdown if your PAM provider is Hashicorp Vault (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining field in the dialog will then be:

- KV Secret Key—The key of the secret to retrieve from the Hashicorp Vault.
- KV Secret Name—The name of the secret to retrieve from the Hashicorp Vault.
- Token Endpoint: The URL of the token endpoint for your Keyfactor Identity Provider instance.
   For example:

https://my-keyidp-server.keyexample.com/realms/Keyfactor/protocol/openid-connect/token

For Keyfactor Identity Provider, this is included among the information that can be found on the OpenID Endpoint Configuration page, a link to which can be found on the Realm Settings page (see *Gathering Keyfactor Identity Provider Data for the Keyfactor Command Installation* in the *Keyfactor Command Server Installation Guide*).

URL: Enter the request URL for the request, including tokens if desired. For a Keyfactor API request, this might look like (with query parameters):

https://keyfactor.keyexample.com/KeyfactorAPI/Certificates?pq.queryString=CN%20-contains%20%22appsrvr14%22%20AND%20CertStorePath%20-ne%20NULL

Or, with tokens:

https://keyfactor.keyexample.com/KeyfactorAPI/Certificates/\$(certid)

**Note**: To prevent REST requests from being made to inappropriate locations by malicious users, configure a system environment variable of KEYFACTOR\_BLOCKED\_
OUTBOUND\_IPS on your Keyfactor Command server pointing to the IP address or range of addresses in CIDR format that you wish to block. Both IPv4 and IPv6 addresses are supported. More than one address or range may be specified in a comma-delimited list. For example:

```
192.168.12.0/24,192.168.14.22/24
```

When a REST request is made where the URL is either configured to a blocked IP address or resolves via DNS to a blocked IP address, the REST request will fail.

- Content-Type: In the dropdown, select the content type for the request:
  - application/json
- Request Content: The request body of the REST request, if required, with tokens, if desired. For
  a Keyfactor API request, this will vary depending on the request and might look like (for a
  PUT / Certificates / Metadata request):

```
{
  "Id": "$(certid)",
  "Metadata":{
     "RevocationComment":"$(cmnt)"
  }
}
```

**Note**: This example assumes you have a metadata field called *RevocationComment* (see Certificate Metadata on page 712).

For an example using a Keyfactor API endpoint within a PowerShell script, see <u>Use Custom Power-Shell with Embedded REST Request</u>, <u>Send Email</u>, <u>and Require Approval on page 267</u>. For an example using an Invoke REST Request to do a data lookup on enrollment, see <u>Invoke REST Request for Data Lookup on Enrollment on page 255</u>.

Invoke REST Request and Set Variable Data with Variable Passing

The following example takes the revocation comment entered when a certificate is revoked and puts it together with some other information into a custom metadata field, retaining any existing data in that metadata field. This example uses both a PowerShell step and a REST Request step to demonstrate passing of information from one step to the other.

To do this, first create the PowerShell step. Here we use a *Set Variable Data* step (see <u>Set Variable Data</u> on page 276) since no functions need to be called outside the confines of Keyfactor Command, though you could use a *Custom PowerShell Script* step instead. Add Script Parameters to pull the revocation comment, submission date, revocation code, user making the revocation request, and the

metadata field into which you will place your updated comment (*Notes* in this example) into the script. Figure 175: Metadata Update Example: Add Parameters shows only four of these. The metadata field *Notes* is a BigText type field in this example (see Metadata Field Operations on page 712).

Figure 175: Metadata Update Example: Add Parameters

In the Insert PowerShell Script field, enter a script similar to the following:

```
# Declare your parameters at the beginning ($Comment, $Notes, $RevCode, $Date, and $RevokeBy)
param(
   [string]$Comment,
   [string]$Notes,
   [string]$RevCode,
   [datetime]$Date
   [string]$RevokeBy
)
# Append your additional text to the existing text in the metadata Notes field along with the revoker
(removing
# the leading 'DOMAIN\' part), submission date, revocation code, and comment entered at revocation,
# and beginning the entry with a newline.
$Notes += "`nRevoked on " + $Date.ToString("MMMM d, yyyy") + " by " + $RevokeBy.SubString
(\Re evokeBy.IndexOf('\')+1) + " with revocation option '" + \Re evCode + "' and comment '" + \Re evCode + "'
"'."
# Return the updated metadata Notes value as MyNotes to the workflow as a hashtable
$result = @{ "MyNotes" = $Notes }
return $result
```

Next, create the REST request step with the following values:

• Headers: The API version does not need to be stated since version 1 is the default.

```
{
    "x-keyfactor-requested-with": [
        "APIClient"
    ]
}
```

Figure 176: Metadata Update Example: Add Headers for REST Request

- Variable to Store Response in: None (there is no output from this command on a success)
- Verb: PUT
- **Client ID**: The client ID from your Keyfactor Identity Provider implementation (see *Create Service Accounts for the Keyfactor API* in the *Keyfactor API Reference Guide*). For example:

```
Keyfactor-API-Workflow-User
```

• Client Secret: The client secret from your Keyfactor Identity Provider implementation (see Create Service Accounts for the Keyfactor API in the Keyfactor API Reference Guide). For example:

```
WDBvGypDWuquyOmQQneeQp4IvmPDebz4
```

• **Token Endpoint**: The token endpoint from your Keyfactor Identity Provider implementation. For example:

```
https://my-keyidp-server.keyexample.com/realms/Keyfactor/protocol/openid-connect/token
```

• URL: (Where keyfactor.keyexample.com is your Keyfactor Command server name.)

```
https://keyfactor.keyexample.com/KeyfactorAPI/Certificates/Metadata
```

- Content-Type: application/json
- Request Content:

```
{
   "Id": "$(certid)",
   "Metadata": {
       "Notes": "$(MyNotes)"
   }
}
```

This REST step takes the MyNotes output from the PowerShell step and updates the metadata Notes field to match that value. The resulting value in your Notes field will look something like this (assuming lines one, two and three were preexisting):

Here is line one.
Here is line two.
Here is line three.
Revoked on June 25, 2022 by jsmith with revocation option 'Superseded' and comment 'Here is a comment about revocation'.

Figure 177: Metadata Update Example: Results

**Note**: You can achieve this same result of updating a metadata field entirely within Power-Shell without using the REST step. This example uses both PowerShell and REST steps to demonstrate passing a value from one to the other.

**Note**: If your REST request takes a long time to complete, the step may time out and the workflow instance fail. The default timeout is 60 seconds and is configurable with the *Workflow Step Run Timeout* application setting (see Application Settings: Workflow Tab on page 622).

## **Require Approval**

Tip: Tokens (a.k.a. substitutable special text) may be used in the subject line, message and email recipient fields. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can select \$(requester) in the workflow definition for an enrollment request and the email message will contain the specific certificate requester name instead of the variable \$(requester). Fields that support tokens are indicated with \$() at the top right of the field. To use a token in a field, begin typing at the location where you want the token to appear, starting with \$(). Once you have typed \$(), a second ) will appear automatically along with a dropdown of available tokens to choose from. You may continue typing to narrow the values in the dropdown (e.g. type \$(req to see only tokens that begin "req").

**Note:** The users who will approve or deny the request must be members of a security role that is allowed to submit signals (e.g. approve requests) for the workflow in order to approve or deny the request.

- Minimum Approvals: Enter the minimum number of users who must approve the request to consider the request approved.
- **Denial Email Subject**: Enter the subject line for the email message that will be delivered if the request is denied, including tokens if desired.
- Denial Email Message: Enter the email message that will be delivered if the request is denied.
  The email message can be made up of regular text and tokens. If desired, you can format the
  message body using HTML. See <u>Table 11: Tokens for Workflow Definitions</u> for a complete list of
  available tokens.
- Denial Email Recipients: Click Add, enter a recipient for the denial email, and Save. Each email
  message can have multiple recipients. You can use specific email addresses and/or use tokens
  to replace an email address variable with actual email addresses at processing time. Available
  email tokens include:
  - \$(requester:mail)

The certificate requester, based on a lookup in Active Directory of the email address associated with the requester on the certificate.

**Note**: The \$(requester:mail) substitutable special text token is only supported in environments using Active Directory as an identity provider.

- Your custom email-based metadata field, which would be specified similarly to \$(metadata:AppOwnerEmailAddress).
- Approval Email Subject: Enter the subject line for the email message that will be delivered if the request is approved, including tokens if desired.
- Approval Email Message: Enter the email message that will be delivered if the request is approved. The email message can be made up of regular text and tokens. If desired, you can format the message body using HTML. See <u>Table 11: Tokens for Workflow Definitions</u> for a complete list of available tokens.

- · Approval Email Recipients: Click Add, enter a recipient for the approval email, and Save. Each email message can have multiple recipients. You can use specific email addresses and/or use tokens to replace an email address variable with actual email addresses at processing time. Available email tokens include:
  - \$(requester:mail)

The certificate requester, based on a lookup in Active Directory of the email address associated with the requester on the certificate.

Note: The \$(requester:mail) substitutable special text token is only supported in environments using Active Directory as an identity provider.

 Your custom email-based metadata field, which would be specified similarly to \$(metadata:AppOwnerEmailAddress).

Tip: The approval message is delivered before the enrollment actually takes place. To send an email alerting interested parties that the certificate was issued, including a link to download the certificate, use an issued certificate alert (see Issued Certificate Request Alerts on page 188).

Figure 179: Configuration Parameters for a Require Approval Workflow Definition Step

For an example using a require approval step with a condition, see <u>Set Variable Data and Require</u> Approval with a Condition on page 249.

Use Custom PowerShell with Embedded REST Request, Send Email, and Require Approval

The following example takes information from an enrollment request that is destined for a certificate store and which requires approval and delivers it in an email to the managers designated as approvers of the request to provide them with the information necessary to make the go/no go decision. This example uses a Custom PowerShell step that calls a Keyfactor API method, a Send Email step, and a Require Approval step.

This step needs to be a Use Custom PowerShell step rather than a Set Variable Data step because it calls a Keyfactor API method in a loop within the script. Since the API method needs to be called in a loop to retrieve multiple pieces of data, it's not practical to do this as a separate Invoke REST Request step.

To do this, first outside of Keyfactor Command create your PowerShell script containing content similar to the following:

```
# Declare your parameters at the beginning
param(
   [string]$StoreData,
   [string]$TimeData
)
# Pick one authentication mechanism for the Keyfactor API
# Basic authentication credentials to authenticate to the Keyfactor API
$user = 'KEYEXAMPLE\APIUser'
$pass = 'APIUserSuperSecretPassword'
# Encode Basic authentication credentials
$pair = "$($cred.Username):$($cred.GetNetworkCredential().Password)"
$encodedCreds = [System.Convert]::ToBase64String([System.Text.Encoding]::ASCII.GetBytes($pair))
$basicAuthValue = "Basic $encodedCreds"
# Token authentication credentials to authenticate to the Keyfactor API (uncomment the below 9 lines
and update appropriately to use token authentication)
#$TokenBody = @{
# grant_type = "client_credentials"
# client_id = "Keyfactor-API-Workflow-User"
# client_secret = "WorkflowAPIClientSecret"
#}
#$TokenHeaders = @{
  'Content-Type' = 'application/x-www-form-urlencoded'
#}
#$TokenURL = "https://appsrvr18.keyexample.com:1443/realms/Keyfactor/protocol/openid-connect/token"
# Request token from Keyfactor Identity Provider for token authentication (uncomment the below line
to use token authentication)
#$TokenValue = Invoke-RestMethod -Method Post -Uri $TokenURL -Headers $TokenHeaders -Body $TokenBody
# Pick an authentication type for the header
$headerAuth = $basicAuthValue
#$headerAuth = "Bearer " + $TokenValue.access_token
# Build the headers for the API request
$headers = @{
   "Authorization"=$headerAuth
   "Accept"="application/json"
   "x-keyfactor-requested-with"="APIClient"
```

```
}
# Convert incoming data from JSON
$StoreDataInfo = $StoreData | ConvertFrom-Json
$TimeDataInfo = $TimeData | ConvertFrom-Json
# Initialize Variables introduced in script
$JobTime = ""
$JobTimeHuman = ""
$TimeMessage = ""
$StoreMessage = ""
$StoreList = New-Object System.Collections.Generic.List[System.Object]
$CommandServer = 'keyfactor.keyexample.com'
# Evalulate the scheduled delivery time for the certificate store management job, if present, and
populate a return message based on the content
if ("Immediate" -in $TimeDataInfo.PSobject.Properties.Name)
        $TimeMessage = "The certificate has been scheduled to be delivered at the next orchestrator run."
}
elseif ("ExactlyOnce" -in $TimeDataInfo.PSobject.Properties.Name)
        # Convert the certificate store job time to a human readable date/time
        $JobTime = [DateTime]($TimeDataInfo.ExactlyOnce.Time)
        $JobTimeHuman = $JobTime.ToString("M/dd/yyyy h:mm tt")
        $TimeMessage = "The certificate has been scheduled to be delivered at the following time:
$JobTimeHuman."
}
else
        $TimeMessage = " "
}
# Pull out the display names of the certificate stores based on the store IDs in the incoming store
foreach ($Store in $StoreDataInfo){
        $response = Invoke-WebRequest -Uri "https://$($Com-
\verb|mandServer|| / \texttt{KeyfactorAPI/CertificateStores/\$(\$store.StoreId)"} - \texttt{Method:Get} - \texttt{Headers} \$ \text{headers} - \texttt{Method:Get} - \texttt{Method:G
ContentType "application/json" -ErrorAction:Stop -TimeoutSec 60
         $responseContent = $response.Content | ConvertFrom-Json
        #Add the store to the store list
         $StoreList.Add($responseContent.DisplayName)
```

```
}
# Evaluate whether any stores were returned and build a message that includes the store list if so,
and an alternate message if not
if ($StoreList.Count -gt 0)
{
   $StoreMessage = "If approved, the certificate will be delivered to the following stores:<br/>
<br/>
'><br
/>" + ($StoreList -join "<br />")
}
else
{
   $StoreMessage = "If approved, the certificate will be available for download in the Keyfactor
Command Management Portal. It has not been scheduled for delivery to any certificate stores."
}
# Return the time message and store message to the workflow as a hashtable
$result = @{ "TimeMessage" = $TimeMessage; "StoreMessage" = $StoreMessage }
return $result
```

**Note**: The method of providing authentication to Keyfactor Command for the Keyfactor API request in this script will vary depending on the authentication configuration of your Keyfactor Command implementation. The above script includes both Basic authentication (for environments using Active Directory as an identity provider) and Token authentication (for environments using Keyfactor Identity Provider as an identity provider) for demonstration purposes, but you should use only one type of authentication. For more information on authenticating to the Keyfactor API in the Keyfactor API Reference Guide).

Next, use the *POST /Extension/Scripts* API endpoint (see <u>POST Extensions Scripts</u>) to import your PowerShell script into the Keyfactor Command database before beginning to edit your workflow.

Once your PowerShell script has been imported into the Keyfactor Command database, you may begin creating your workflow. To create the Use Custom PowerShell step, add *Script Parameters* to pull the certificate store data—\$(Stores)—and schedule time for the management job to add the certificate to the certificate stores—\$(ManagementJobTime)—into the script as shown in Figure 180: Use Custom PowerShell with Embedded REST Request: Add Parameters. The \$(Stores) and \$(ManagementJobTime) tokens are not among those that appear in the dropdown.

Figure 180: Use Custom PowerShell with Embedded REST Request: Add Parameters

In the PowerShell Field Name field, in the dropdown select the script you uploaded to the database.

Next, create the Send Email step. In the configuration parameters, give your email a Subject that will help highlight the request:

```
ACTION REQUIRED: Certificate Enrollment Request for $(request:cn)
```

This tells your users that they need to do something and includes the CN of the requested certificate in the subject line.

In the main Message of the email, tell your users what they need to do and provide the information from the request that will allow them to make an informed decision using tokens (see <u>Substitutable Text Tokens for Workflow on page 296</u>) and the certificate store information returned from the PowerShell script:

```
Hello,

A certificate using the $(template) template was requested by $(requester:displayname) from $(CA) on $(subdate). $(StoreMessage)

$(TimeMessage)

The certificate details include:

<CN: $(request:cn)</li>
<N: $(request:cn)</li>
<Ali>>SANs: $(sans))
<App Owner First Name: $(metadata:AppOwnerFirstName)</li>
<II>App Owner Last Name: $(metadata:AppOwnerLastName)

Please review this request and issue the certificate as appropriate by going here:
```

```
$(reviewlink)

Thanks!

Your Certificate Management Tool
```

**Note**: The \$(requester:displayname) substitutable special text token is only supported in environments using Active Directory as an identity provider.

In the Recipients, add all the email recipients who could possibly approve or deny the request.

Now create your Require Approval step. The step does not need any Conditions. In the Configuration Parameters, enter a value of at least 1 for the Minimum Required Approvals. Give the Denial Email Subject a value something like:

```
Certificate Enrollment Request Denied for $(request:cn)
```

And the Approval Email Subject a value something like:

```
Certificate Enrollment Request Approved for $(request:cn)
```

Enter an appropriate message for the Denial Email Message. You may use tokens, including the returned values from the PowerShell script. You may want to deliver this message to the requester, so a message similar to this might be appropriate:

```
For assistance, please contact <a href="mailto:support@keyexample.com">support@keyexample.com</a>.
Thanks!
Your Certificate Management System
```

**Note**: The \$(requester:givenname) substitutable special text token is only supported in environments using Active Directory as an identity provider.

Enter an appropriate message for the Approval Email Message. This message would also likely go to the requester and might look similar to:

```
Hello $(requester:givenname),
The certificate you requested in the name $(request:cn) on $(subdate) was successfully approved with
the following comment:
$(approvalsignalcmnts)
The certificate details include:
  <l
     CN: $(request:cn)
     DN: $(request:dn)
     SANs: $(sans))
     App Owner First Name: $(metadata:AppOwnerFirstName)
     App Owner Last Name: $(metadata:AppOwnerLastName)
  You will receive an update when it has been issued. For assistance, please contact <a href-
f="mailto:support@keyexample.com">support@keyexample.com</a>.
Thanks!
Your Certificate Management System
```

**Note:** The \$(requester:givenname) substitutable special text token is only supported in environments using Active Directory as an identity provider.

In the Recipients for both the approval and denial emails, enter the token for the requester's email—\$(requester:mail).

**Note**: The \$(requester:mail) substitutable special text token is only supported in environments using Active Directory as an identity provider.

In the Signals for the Require Approval step, select the security role(s) to which the users responsible for approving or denying the request belong.

Finish off the workflow process by configuring an issued certificate request alert to let the requester know when the certificate has been issued (see Issued Certificate Request Alerts on page 188).

#### Send Email

Tip: Tokens (a.k.a. substitutable special text) may be used in the subject line, message and email recipient fields. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can select \$(requester) in the workflow definition for an enrollment request and the email message will contain the specific certificate requester name instead of the variable \$(requester). Fields that support tokens are indicated with \$0 at the top right of the field. To use a token in a field, begin typing at the location where you want the token to appear, starting with \$(. Once you have typed \$(, a second ) will appear automatically along with a dropdown of available tokens to choose from. You may continue typing to narrow the values in the dropdown (e.g. type \$(req to see only tokens that begin "req").

Figure 181: Tokens are Highlighted

- Subject: Enter the subject line for the email message that will be delivered when the workflow
  definition step is executed, including tokens if desired.
- Message: Enter the email message that will be delivered when the workflow definition step is
  executed. The email message can be made up of regular text and tokens. If desired, you can
  format the message body using HTML. For example, for an enrollment pending request notification:

Hello,

A certificate using the \$(template) template was requested by \$(requester:displayname) from \$(CA) on \$(subdate). The certificate details include:

Certificate DetailsMetadata

CN: \$(request:cn)App Owner First Name: \$(metadata:Ap-

pOwnerFirstName)

DN: \$(request:dn)App Owner Last Name:

\$(metadata:AppOwnerLastName)

SANs: \$(sans)App Owner Email Address: \$(metadata:Ap-

pOwnerEmailAddress)

Business Critical: \$(metadata:BusinessCritical)

Please review this request and issue the certificate as appropriate by going here:

\$(reviewlink)

Thanks!

Your Certificate Management Tool

See Table 11: Tokens for Workflow Definitions for a list of available tokens.

**Note:** The \$(requester:displayname) substitutable special text token is only supported in environments using Active Directory as an identity provider.

- **Recipients**: Click **Add**, enter a recipient for the email, and **Save**. Each email message can have multiple recipients. You can use specific email addresses and/or use tokens to replace an email address variable with actual email addresses at processing time. Available email tokens include:
  - \$(requester:mail)

The certificate requester, based on a lookup in Active Directory of the email address associated with the requester on the certificate.

**Note**: The \$(requester:mail) substitutable special text token is only supported in environments using Active Directory as an identity provider.

 Your custom email-based metadata field, which would be specified similarly to \$(metadata:AppOwnerEmailAddress).

Figure 182: Step Configuration for an Email Workflow Definition Step

For an example using Send Email in a Require Approval workflow, see <u>Use Custom PowerShell with Embedded REST Request</u>, Send Email, and Require Approval on page 267.

### Set Variable Data

**Tip:** Tokens (a.k.a. substitutable special text) may be used in the script parameter value field. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can take the revocation comment entered when the revocation request is approved—\$(cmnt)—and append additional data to it using PowerShell.

 Script Parameters: Add any parameters you will use to pass data into your script. These can contain static values or tokens (see <u>Table 11: Tokens for Workflow Definitions</u>). To add a parameter:

- 1. In the Script Parameters section, click Add.
- 2. In the Add/Edit Parameter dialog, enter a name for the parameter in the **Parameter** field. In the **Value** field, enter either a static value to be passed into the PowerShell script or select from the available tokens to pass the token value into the PowerShell in your parameter.
- 3. Click **Save** to save your parameter.

Figure 183: Add Parameters for PowerShell

• Insert PowerShell Script: Enter the PowerShell commands to execute. This should be the actual contents of the PowerShell script (the PowerShell commands and supporting components), not a path and filename to an external file.

To receive your defined parameters from the previous step into the PowerShell script, begin the script by declaring the expected parameters like so (referencing the three parameters—TestOne, TestTwo, and TestThree):

```
param(
  [string]$TestOne,
  [int]$TestTwo,
  [string]$TestThree
)
```

You may then use these parameters within the script.

To return data from the PowerShell script, create a hashtable of the data you wish to return like so (where \$MyField1 and \$MyField2 are parameters introduced within the script and the new value in \$TestThree is reloaded back into that parameter and used to update that field if the original parameter was set to a token):

```
$result = @{ "MyFieldOne" = $MyField1; "MyFieldTwo" = $MyField2; "TestThree" = $TestThree }
return $result
```

This will result in the following dictionary entries being added to the database and available for output or use in subsequent steps in the workflow:

```
{["MyFieldOne", "[your value as defined in the script"], ["MyFieldTwo", "[your value as defined in the script"], ["TestThree", "[your value as defined in the script"],]}
```

You can reference these as tokens in subsequent steps as follows: \$(MyFieldOne), \$(MyFieldTwo), \$(TestThree).

Figure 184: Configuration Parameters for a Set Variable Data Workflow Definition Step

Set Variable Data for Revocation

The following example takes the revocation comment entered when a certificate is revoked and appends an additional comment, including dates, to it. To create this, add Script Parameters to pull the revocation comment, submission date and effective date into the Set Variable Data script as shown in Figure 175: Metadata Update Example: Add Parameters.

Figure 185: Revocation Comment Update Example: Add Parameters

In the Insert PowerShell Script field, enter a script similar to the following:

```
# Declare your parameters at the beginning ($Comment, $SDate, and $Edate)
param(
    [string]$Comment,
    [datetime]$SDate,
    [datetime]$EDate
)

# Append your additional text to the existing comment along with the submission and effective dates
$Comment += " - Revocation requested on " + $SDate.ToString("g") + " and effective on " +
$EDate.ToString("g")

# Return the updated comment to the workflow in the original parameter as a hashtable
$result = @{ "Comment" = $Comment }
return $result
```

The resulting comment will look something like:

Figure 186: Revocation Comment Update Example: Results

You may reference the updated comment using the standard revocation comment token (\$(cmnt)) in subsequent steps in your workflow and may view the updated comment wherever the revocation comment is available for viewing within Keyfactor Command.

#### Set Variable Data for Enrollment

The following example takes two additional enrollment fields submitted on an enrollment and sets the value of one to a fixed value if the value of the other (a multi-value field) is a given value using a Set Variable Data script. In other words, the possible values for Department (a multi-value field) are:

- Accounting
- E-Commerce
- HR
- IT
- Marketing
- R&D
- Sales

If the value of Department is anything other than Accounting, the value of Code (a string field) can be any value. If the value of Department is Accounting, anything submitted in the Code field by the end user is discarded and replaced by the fixed value for Code provided in the script.

This example provides a solution using a *Set Variable Data* step type and demonstrates manually unpacking the JSON attribute string. One possible method of doing this is provided in the example. If you prefer, you may instead use the *ConvertFrom-Json* cmdlet similarly to the example for putting approval comments in a metadata field and avoid the manual string manipulation steps.

To create this, add Script Parameters to pull the additional attributes into the script as shown in Figure 187: Additional Attribute Update Example: Add Parameters

Figure 187: Additional Attribute Update Example: Add Parameters

In the Insert PowerShell Script field, enter a script similar to the following:

```
# Declare your parameters at the beginning
   [string]$AdditionalAttributes
)
# Trim brackets off incoming attribute string
$TrimmedAttributes = $AdditionalAttributes.Substring(1,$AdditionalAttributes.Length-2)
# Replace commas bracketed by quotes in attribute string with a temporary string to facilitate split-
ting (assumes no incoming values contain temp string)
$TempString = "`"#####"""
$CleanAttributes = $TrimmedAttributes -replace "`",`"", $TempString
# Split the incoming attribute string into its component values at the temporary string
$SplitAttributes = $CleanAttributes.Split('#####")
# Split the incoming attribute string key/value pairs
foreach($attribute in $SplitAttributes){
   $attributeComponents = $attribute.Trim() -split ":"
   $attributeComponents
   Switch($attributeComponents[0].Trim()){
      '"Department"' {$Department = $attributeComponents[1].Substring(1,$attributeComponents
[1].Length-2)}
      '"Code"' {$Code = $attributeComponents[1].Substring(1,$attributeComponents[1].Length-2)}
   }
}
# Initialize a hashtable
$UpdatedAttributes = @{}
# Load original attributes in UpdatedAttributes for the else case
if(![string]::IsNullOrWhiteSpace($Code)) {
```

```
$UpdatedAttributes['Code'] = $Code
}
if(![string]::IsNullOrWhiteSpace($Department)) {
    $UpdatedAttributes['Department'] = $Department
}

# If the value of Department is "Accounting", then the value of Code must be "G5N145"; override submitted value--if any--and use fixed value
if($UpdatedAttributes['Department'] -eq "Accounting") {
    $UpdatedAttributes['Code'] = "G5N145"
}

# Return the updated attributes to the workflow in the original parameter as a hashtable $result = @{ "AdditionalAttributes" = $UpdatedAttributes } return $result
```

The updated attributes will be submitted to the CA as part of the enrollment package and can be viewed in the workflow instance (see Viewing a Workflow Instance on page 317).

#### **Use Custom PowerShell**

**Tip:** Tokens (a.k.a. substitutable special text) may be used in the script parameter value field. Tokens use a variable in the workflow definition that is replaced by data from the certificate request, certificate, or certificate metadata at processing time. For example, you can take the revocation comment entered when the revocation request is approved—\$(cmnt)—and append additional data to it using PowerShell.

**Important:** Before adding the Use Custom PowerShell step to your workflow, you must upload the script for the step into the Keyfactor Command database using the *POST /Extension/Scripts* API endpoint (see *Extensions/Scripts* and *POST Extension Scripts* in the *Keyfactor API Reference Guide*). If you open the workflow definition for editing before adding the script, it will not appear as an available script in the configuration dropdown.

- Script Parameters: Add any parameters you will use to pass data into your script. These can
  contain static values or tokens (see <u>Table 11: Tokens for Workflow Definitions</u>). To add a parameter:
  - 1. In the Script Parameters section, click Add.
  - 2. In the Add/Edit Parameter dialog, enter a name for the parameter in the **Parameter** field. In the **Value** field, enter either a static value to be passed into the PowerShell script or select from the available tokens to pass the token value into the PowerShell in your parameter.
  - 3. Click Save to save your parameter.

Figure 188: Add Parameters for PowerShell

• PowerShell Script Name: The script contents are stored in the Keyfactor Command database. After uploading your script to the database, select a script from the dropdown on the step. All scripts in the database that have been configured for the workflow will be available for selection. See Extensions/Scripts in the Keyfactor API Reference Guide for information on adding scripts to the database. The file must be in JSON-escaped format and have an extension of .ps1. The script should use the same input and output method for parameters as described for the Set Variable Data step type (see Set Variable Data on page 276).

**Tip:** A sample PowerShell script, **CustomPowershellExample.ps1**, is provided in the workflow directory (default: *C:\Program Files\Keyfactor\Keyfactor Plat-form\ExtensionLibrary\Workflow*).

Figure 189: Step Configuration for a Custom PowerShell Workflow Definition Step

# Use Custom PowerShell for Enrollment

The following example takes the common name entered during an enrollment and evaluates it to determine whether the domain suffix ends with "keyexample.com". If it does, the script does a DNS lookup of the full CN to find the IPv4 address for that name and, if found, adds that value as a SAN to the request. Two additional SANs are added to the request by removing the "keyexample.com" domain suffix and instead appending the domain suffixes provided in the Domain1 and Domain2 parameters (e.g. mycert.keyother.com and mycert.keyother2.com). If the CN does not have a domain suffix ending with "keyexample.com", the PowerShell script does nothing.

This step needs to be a *Use Custom PowerShell* step rather than a *Set Variable Data* step because it calls a PowerShell command (*Resolve-DnsName*) that exists outside the confines of Keyfactor Command.

To do this, first use the *POST /Extension/Scripts* API endpoint (see <u>POST Extensions Scripts</u>) to import your PowerShell script into the Keyfactor Command database before beginning to edit your workflow. Your script file prior to import should contain content similar to the following:

```
# Declare your parameters at the beginning ($InputCN, $Domain1, $Domain2, and $InputSANs)
param(
   [string]$InputCN,
   [string]$Domain1,
   [int]$Domain2,
   [string]$InputSANs
)
# Split the incoming SANs string into its component values
$SplitSANs = $InputSANs.Split(',')
# Initialize variables for the two types of SANs we're handling
DnsSans = @()
psans = @()
# Add the incoming SANs to the correct list (assumes only IPv4 addresses or DNS SANs will be
encountered)
foreach($san in $SplitSANs){
   $sanComponents = $san.Trim() -split ":"
   Switch ($sanComponents[0].Trim()){
      "DnsName" {$DnsSans += ,$sanComponents[1].Trim()}
      "IPAddress" {$IpSans += $sanComponents[1].Trim()}
   }
}
# Check to see if the incoming CN ends with keyexample.com and, if so, add some SANs.
$Suffix = "keyexample.com"
if ($InputCN.EndsWith($Suffix))
{
   # Load just the portion of the CN without the domain name into a variable.
   $CNName = $InputCN.SubString(0,$InputCN.Length - $Suffix.Length)
   # Do a lookup on the requested CN to find its IPv4 address.
   $IPResult = Resolve-DnsName -Name $InputCN -Type A -ErrorAction SilentlyContinue
   # If an address is found, add that address as a SAN.
   # Also add SANs built with the contents of Domain1, Domain2, and the leading part of the CN
   # (e.g. mycert.my-first-other-domain.com and mycert.my-second-other-domain.com).
   if ($IPResult -ne $null)
```

```
$SAN1 = $IPResult.IPAddress
      $SAN2 = $CNName + $Domain1
      $SAN3 = $CNName + $Domain2
      $DnsSans += ,$SAN2
      $DnsSans += ,$SAN3
      $IpSans += ,$SAN1
   # If an IP address is not found, add only the SANs featuring Domain1 and Domain2.
   else {
      $SAN2 = $CNName + $Domain1
      $SAN3 = $CNName + $Domain2
      $DnsSans += ,$SAN2
     $DnsSans += ,$SAN3
  }
}
# Load the resulting IPv4 and DNS SANs into the SANS variable
$UpdatedSANs = @{}
if(![string]::IsNullOrWhiteSpace($DnsSans)) {
   $UpdatedSANs['dns'] = $DnsSans
}
if(![string]::IsNullOrWhiteSpace($IpSans)) {
   $UpdatedSANs['ip4'] = $IpSans
}
# Return the updated SANs to the workflow as a hashtable (case matters in the return value name
"SANs" in order
# to reload the results back into the SANs token)
$result = @{ "SANs" = $UpdatedSANs; }
return $result
```

Once your PowerShell script has been imported into the Keyfactor Command database, you may begin creating your workflow. To create the Use Custom PowerShell step, add *Script Parameters* to pull the CN and SANs into the script as shown in <a href="Metadata Update Example: Add Parameters on page 262">Metadata Update Example: Add Parameters on page 262</a>, and add to static values to pass in your two additional domain names.

Figure 190: Update SANs Example: Add Parameters

In the PowerShell Script Name field dropdown, select the script you uploaded to the database.

Your enrollment will complete using the updated list of SANs, including any SANs you added manually on the PFX enrollment page or in the CSR. You may reference the updated SANs using the standard SANs token (\$(sans)) in subsequent steps in your workflow and may view the complete SAN list wherever the SANs are available for viewing within Keyfactor Command.

**Note**: If you're using a Microsoft CA, in order to add SANs in the workflow you will need to do one of the following:

- Include an Update Certificate Request Subject\SANs step in your workflow (see <u>Update Certificate Request Subject\SANs for Microsoft CAs on page 289</u>). This is Keyfactor's preferred solution for workflow due to the limited risk profile.
- Use Keyfactor's SAN Attribute Policy Handler (see *Installing the Keyfactor CA Policy Module Handlers*). This opens security risks as well, which can be mitigated, however, this is not Keyfactor's preferred solution for workflow.
- Configure your CA to support the addition of SANs outside the initial request (enable the EDITF\_ATTRIBUTESUBJECTALTNAME2 flag). Keyfactor does not recommend this solution due to the inherent security risks.

Use Custom PowerShell and Require Approval

The following example takes the approval comment entered when a certificate is enrolled or the approval or denial comment entered when a certificate is revoked using a require approval step and stores the comment in a metadata field. There will be no certificate to associate the metadata field with for an enrollment request that is denied. Normally, approval and denial comments are discarded after a workflow instance is complete, so this allows the comment to be retained.

This example uses a *Use Custom PowerShell* step **after** the *Require Approval* step(s) in the workflow. The Use Custom PowerShell step needs to come after the Require Approval step so that it can include comments gathered from the approve/deny requests.

To do this, first use the *POST /Extension/Scripts* API endpoint (see <u>POST Extensions Scripts</u>) to import your PowerShell script into the Keyfactor Command database before beginning to edit your workflow. Your script file prior to import should contain content similar to the following:

```
# Declare your parameters at the beginning
param(
   [string]$ApprovalComment,
   [string]$SignalComment,
   [string]$Metadata
)
# Initialize a hashtable to contain your metadata fields and populate it
$UpdatedMetadata = @{}
$jsonobject = $Metadata | ConvertFrom-Json
foreach( $property in $jsonobject.PSObject.Properties )
   $UpdatedMetadata[$property.Name] = $property.Value
}
# Append your signal comment(s) to any existing comment in the ApprovalComment metadata field
if([string]::IsNullOrWhiteSpace($ApprovalComment)) {
   $UpdatedMetadata['ApprovalComment'] = $SignalComment
}else {
   $UpdatedMetadata['ApprovalComment'] = $ApprovalComment + ", " + $SignalComment
}
# Return the updated metadata fields, including ApprovalComment, to the workflow in the original para-
meter as a hashtable
$result = @{ "ApprovalComment" = $UpdatedMetadata }
return $result
```

Once your PowerShell script has been imported into the Keyfactor Command database, you may begin creating your workflow. To create the Use Custom PowerShell step, add *Script Parameters* to pull any approval comments and the metadata field you're planning to store them in (in this example, a field called ApprovalComments) into the script, along with the metadata bucket to include any remaining metadata values, as shown in <u>Figure 191: Approval Comment Update Example: Add Parameters</u>.

Figure 191: Approval Comment Update Example: Add Parameters

In the PowerShell Script Name field dropdown, select the script you uploaded to the database.

The resulting comment will look something like:

Figure 192: Approval Comment Update Example: Results

If the workflow requires multiple approvals or has multiple require approval steps, all the approval comments entered in the given workflow instance prior to the PowerShell step will be added to the metadata field. If you expect to have multiple comments, you may prefer to use a big text field rather than the string type fields shown here.

**Note**: If your PowerShell script takes a long time to execute, the step may time out and the workflow instance fail. The default timeout is 60 seconds and is configurable with the *Workflow Step Run Timeout* application setting (see <u>Application Settings: Workflow Tab on page 622)</u>.

## Update Certificate Request Subject\SANs for Microsoft CAs

This step is used to create a new signed CSR to prepare an updated enrollment request for delivery to a Microsoft CA after a previous step in the workflow has been used to update either the SANs in the initial request, subject (DN) in the initial request or both. This step must be placed later in the workflow than the step(s) that modify the SANs and/or subject. The SANs and subject may be modified with either of the PowerShell step types (see Set Variable Data on page 276 and Use Custom

PowerShell on page 282) or a custom step type. This step is used for both PFX enrollment and CSR enrollment, since both use a CSR that is generated at the start of the workflow. A Microsoft CA will not accept a CSR for enrollment if the subject has been modified and will only accept a CSR for enrollment with modified SANs if the EDITF\_ATTRIBUTESUBJECTALTNAME2 flag has been enabled on the CA—a security risk Keyfactor does not recommend. EJBCA doesn't support enroll on behalf of (EOBO), so this step type does not apply to EJBCA CAs. EJBCA is able to handle subject and SAN changes without the need for this type of step based on end entity profile constraints.

- Enrollment Agent Certificate: Click Browse to search for the desired base-64 encoded PKCS#12 (.PFX) enrollment agent certificate with private key to sign the CSR. This can be either a user certificate or a computer certificate and must have a Certificate Request Agent EKU.
- Set Private Key Password: The password for the enrollment agent certificate. Click Set Private
  Key Password to open the Private Key Password dialog. Choose the No Value checkbox to not
  assign a password, or choose from Load From Keyfactor Secrets or Load From PAM Provider.

A Keyfactor secret is a user-defined password or other information that is encrypted and stored securely in the Keyfactor Command database. Although Keyfactor recommends using Privileged Access Management (see <a href="Privileged Access Management (PAM)">Privileged Access Management (PAM)</a> on page 744) as a more secure solution to secure information, Keyfactor Secret is an option for customers that do not already have a relationship with a PAM provider such as CyberArk or Delinea.

Important: Keyfactor highly recommends that you use strong passwords for any accounts or certificates related to Keyfactor Command and associated products, especially when these have elevated or administrative access. A strong password has at least 12 characters (more is better) and multiple character classes (lowercase letters, uppercase letters, numeral, and symbols). Ideally, each password would be randomly generated. Avoid password re-use.

Select the **Load From Keyfactor Secrets** radio button as the *Secret Source* if you want Keyfactor Command to encrypt and store the password in the Keyfactor Command database. Enter and confirm a password.

Select the **Load from PAM Provider** radio button as the *Secret Source* if you want to store the password in a supported third-party PAM solution (see <u>Privileged Access Management (PAM) on page 744</u>). The remaining fields on the dialog will vary depending on the PAM provider. For example:

#### CyberArk

Select your CyberArk provider in the **Providers** dropdown if your PAM provider is CyberArk (see Adding or Modifying a PAM Provider on page 752). The remaining fields in the dialog will then be:

- ° Safe—The name of the safe the credential resides in.
- Object—The name of the username or password object in the safe.
- Folder—The path and name of the folder that stores the object (e.g. Root or Root\MyDir).

## Delinea

Select your Delinea provider in the **Providers** dropdown if your PAM provider is Delinea (see Adding or Modifying a PAM Provider on page 752). The remaining field in the dialog will then be:

- ° Secret Server Secret ID—The numeric ID of the secret to retrieve from Secret Server.
- Secret Field Name—The name of the field to use when retrieving a secret form Secret Server.

# Hashicorp

Select your Hashicorp Vault provider in the **Providers** dropdown if your PAM provider is Hashicorp Vault (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining field in the dialog will then be:

- ° KV Secret Key—The key of the secret to retrieve from the Hashicorp Vault.
- KV Secret Name—The name of the secret to retrieve from the Hashicorp Vault.

Figure 193: Update Certificate Request Subject\SANs for Microsoft CAs Workflow Definition Step

# Update Certificate Request Subject\SANS for MSFT CAs

The following example uses PowerShell to take the distinguished name (subject) and SANs entered during an enrollment along with two static domain names and evaluates the domain name of the common name in the subject to determine whether the domain suffix ends with the "original" domain name provided in the static value ("keyexample.com"). If it does, the script replaces the domain name in the subject with the value provided by the "new" static value and adds a SAN with CN prefix and the new domain name (e.g. CN=mycert.keyexample.com becomes CN=mycert.keyother.com and a SAN is added for mycert.keyother.com). If the CN does not have a domain suffix ending with "keyexample.com", the PowerShell script does nothing. Here we use a Set Variable Data step (see Set Variable Data on page 276) since no functions need to be called outside the confines of Keyfactor Command, though you could use a Custom PowerShell Script step instead. Then an Update Certificate Subject\SANs for Microsoft CAs step is used to re-sign the request before it is submitted to the CA.

To create this, add Script Parameters to pull the DN and SANs into the script as shown in <a href="Metadata">Metadata</a></a>Update Example: Add Parameters on page 262 and add two static values to pass in your two domain names.

Figure 194: Update SANs and Subject Example: Add Parameters

In the Insert PowerShell Script field, enter a script similar to the following:

```
# Declare your parameters at the beginning
param(
   [string]$CSRSubject,
   [string]$CSRSANs,
   [string]$OriginalDomain,
   [string]$NewDomain
)
# Split the incoming SANs string into its component values
$SplitSANs = $CSRSANs.Split(',')
# Initialize variables for the two types of SANs we're handling
DnsSANs = @()
psans = @()
# Add the incoming SANs to the correct list (assumes only IPv4 addresses or DNS SANs will be
encountered)
foreach($san in $SplitSANs){
   $sanComponents = $san.Trim() -split ":"
   Switch ($sanComponents[0].Trim()){
      "DnsName" {$DnsSANs += ,$sanComponents[1].Trim()}
      "IPAddress" {$IpSANs += $sanComponents[1].Trim()}
   }
}
# Load original SANs in UpdatedSANs for the else case
$UpdatedSANs = @{}
if(![string]::IsNullOrWhiteSpace($DnsSANs)) {
```

```
$UpdatedSANs['dns'] = $DnsSANs
}
if(![string]::IsNullOrWhiteSpace($IpSANs)) {
   $UpdatedSANs['ip4'] = $IpSANs
}
# Load original subject in NewSubject for the else case
$NewSubject = $CSRSubject
# Replace escaped commas in the subject temporarily with a string to facilitate splitting
$TempString = "#####"
$CleanSubject = $CSRSubject -replace "\\,", $TempString
# Split the incoming Subject string into its component values
$SplitSubject = $CleanSubject.Split(',')
# Initialize variables for the components of the subject
$SubjectCN = @()
$Subject0 = @()
$SubjectOU = @()
$SubjectL = @()
$SubjectST = @()
$SubjectC = @()
$SubjectE = @()
# Load subject values
foreach($element in $SplitSubject){
   $SplitElement = $element.Split('=')
   Switch($SplitElement[0]){
      "CN" {$SubjectCN = $SplitElement[1]}
      "0" {$Subject0 = $SplitElement[1]}
      "OU" {$SubjectOU = $SplitElement[1]}
      "E" {$SubjectE = $SplitElement[1]}
      "L"{$SubjectL = $SplitElement[1]}
      "ST"{$SubjectST = $SplitElement[1]}
      "C"{$SubjectC = $SplitElement[1]}
  }
}
# Check to see if the incoming CN ends with $OriginalDomain and, if so, add it as a SAN with $NewDo-
main and update the Subject with $NewDomain (assumes non-null CN)
if ($SubjectCN.EndsWith($OriginalDomain))
```

```
# Load just the portion of the CN without the domain name into a variable.
        SON(0, Sub) = Subject(N.SubString(0, Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.SubString(0, Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.SubString(0, Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.SubString(0, Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1)) # +1 to account Subject(N.Length - (Soriginal Domain.Length + 1) * +1 to account Subject(N.Length - (Sorigina Domain.Length + 1)) * +1 to account Subject(N.Length - (Sorigi

        # Build new DNS SAN
        $NewSAN = $CNName + "." + $NewDomain
        # Add new SAN to DNS SANs
        $DnsSans += ,$NewSAN
        # Build new Subject with $NewDomain
        $NewSubject = "";
        if(![string]::IsNullOrWhiteSpace($SubjectCN)){
                 $NewSubject += "CN=" + $CNName + "." + $NewDomain + ","
        if(![string]::IsNullOrWhiteSpace($Subject0)){
                 $NewSubject += "O=" + $SubjectO + ","
        }
        if(![string]::IsNullOrWhiteSpace($SubjectOU)){
                 $NewSubject += "OU=" + $SubjectOU + ","
        if(![string]::IsNullOrWhiteSpace($SubjectL)){
                 $NewSubject += "L=" + $SubjectL + ","
        }
        if(![string]::IsNullOrWhiteSpace($SubjectST)){
                 $NewSubject += "ST=" + $SubjectST + ","
        if(![string]::IsNullOrWhiteSpace($SubjectC)){
                 $NewSubject += "C=" + $SubjectC + ","
        }
        if(![string]::IsNullOrWhiteSpace($SubjectE)){
                 $NewSubject += "E=" + $SubjectE + ","
        }
         $NewSubject = $NewSubject.Remove($NewSubject.Length - 1) # remove the last ','
```

```
# Replace temporary string with escaped commas in Subject
$NewSubject = $NewSubject -replace $TempString, "\,"

# Load the resulting IPv4 and updated DNS SANs into the SANs variable
$UpdatedSANs = @{}

if(![string]::IsNullOrWhiteSpace($DnsSANs)) {
    $UpdatedSANs['dns'] = $DnsSANs
}

if(![string]::IsNullOrWhiteSpace($IpSANs)) {
    $UpdatedSANs['ip4'] = $IpSANs
}

# Return the updated subject and SANs as NewSubject and NewSANs to the workflow as a hashtable
$result = @{ "Subject" = $NewSubject; "SANs" = $UpdatedSANs }
return $result
```

Add an Update Certificate Request Subject\SANs for Microsoft CAs step at a point in the workflow **after** your PowerShell step to allow the request to be re-signed before it is submitted to the Microsoft CA for enrollment.

Your enrollment will complete using the updated list of SANs, including any SANs you added manually on the PFX enrollment page or in the CSR, and the updated subject. You may reference the updated SANs using the standard SANs token (\$(sans)) and updated subject using the standard DN token (\$(request:dn)) in subsequent steps in your workflow and may view the subject and complete SAN list wherever the subject and SANs are available for viewing within Keyfactor Command.

## Windows Enrollment Gateway - Populate from AD

This step is needed for any Keyfactor Windows Enrollment Gateway requests where the incoming template (the template from the client side) is configured to build the subject of the certificate request from Active Directory. It has no configuration parameters.

#### **Substitutable Text Tokens for Workflow**

Refer to the following table for a list of the substitutable special text tokens that are available in the dropdown to customize workflow email messages, conditions, and select parameter configuration fields along with a selection of some additional tokens that are not found in the dropdown but which exist in the data bucket (see tip).

**Tip:** In addition to the tokens in the dropdown, any data in the current data bucket can be referenced by entering an appropriate reference string. For example, to return the CSR for

an enrollment request you can use \$(CSR). Refer to the CurrentStateData field in the response to the GET /Workflow/Instances/{instanceId} API method for information on all the data found in the current (as opposed to initial) data bucket (see GET Workflow Instances Instance ID in the Keyfactor API Reference Guide).

Table 11: Tokens for Workflow Definitions

Variable	Name	Request Type	In Drop- down?	Description
\$(Ad- ditionalAttributes)	n/a	Enroll- ment	No	An array containing the additional enrollment fields, if any, in key value pair format.
\$(ap- provalsignalcmnts)	Workflow Approval or Denial Comment	Certificate Collection, Enrollment and Revocation	Yes	The comment provided when a work-flow request that requires approval is approved or denied.
\$(CA)	Issuing CA	Certificate Collection, Enrollment and Revocation	Yes	A string containing the Issuing CA logical name and hostname.
\$(CACertificate)	n/a	Enroll- ment	No	Any array of information about the chain certificate(s) for the request, including the certificate.
\$(certid)	Request ID	Certi- ficate Collection and Revoc- ation	Yes	The request ID for the certificate as stored in the Keyfactor Command database. This is not the same as the request ID issued by the CA.
\$(cmnt)	Revocation Comment	Revoc- ation	Yes	The comment entered at revocation time to explain the revocation.
\$(code)	Revocation	Revoc-	Yes	The reason selected at revocation

Variable	Name	Request Type	In Drop- down?	Description
	Reason	ation		time to explain the revocation as a string (e.g. AffiliationChanged).
\$(cn)	Common Name	Certificate Collection and Revocation	Yes	The certificate common name.
\$(CSR)	n/a	Enroll- ment	No	The CSR generated for the enrollment.
\$(CustomName)	n/a	Enroll- ment	No	The custom friendly name, if any, set for the certificate on enrollment.
\$(dn)	Distin- guished Name	Certi- ficate Collection and Revoc- ation	Yes	The certificate distinguished name.
\$(effdate)	Revocation Effective Date	Revoc- ation	Yes	Date on which the revocation becomes effective.
\$(Format)	n/a	Enroll- ment	No	The value selected during PFX Enrollment for the format for the certificate. Possible values are: JKS, PFX, Store, Zip
\$(IsPFX)	n/a	Enroll- ment	No	A Boolean indicating whether the certificate request was made using the PFX Enrollment method in Keyfactor Command (true) or not (false).
\$(issuerdn)	Issuer DN	Certi- ficate Collection and Revoc- ation	Yes	The distinguished name of the issuer of the certificate.

Variable	Name	Request Type	In Drop- down?	Description
\$(KeyRetention)	n/a	Enroll- ment	No	A Boolean indicating whether the private key for the certificate has been retained in Keyfactor Command (true) or not (false).
\$(keysize)	Key Size	Certi- ficate Collection and Revoc- ation	Yes	The key size of the certificate.
\$(keytype)	Кеу Туре	Certi- ficate Collection and Revoc- ation	Yes	The key type of the certificate.
\$(locations)	Certificate Store Loca- tions	Certificate Collection, Enrollment and Revocation	Yes	The certificate store locations to which the certificate will be deployed following enrollment, for enrollment requests, or in which the certificate is found, for revocation requests.
\$(man- agementjobtime)	n/a	Enroll- ment	No	The schedule for the management job to add the certificate to certificate stores on issuance. The field, if populated, will have a value of either "Immediate": true or "ExactlyOnce" with the date and time at which the management job should begin.
\$(request:cn)	Requested Common Name	Enroll- ment	Yes	The common name contained in the certificate request.
\$(request:dn)	Requested Distin- guished	Enroll- ment	Yes	The distinguished name contained in the certificate request.

Variable	Name	Request Type	In Drop- down?	Description
	Name			
\$(request:keysize)	Request Key Size	Enroll- ment	Yes	The key size contained in the certificate request.
\$(request:keytype)	Request Key Type	Enroll- ment	Yes	The key type contained in the certificate request.
\$(requester)	Requester	Enroll- ment and Revoc- ation	Yes	The user account that requested the certificate from the CA, in the form DOMAIN\username.
\$(requester:mail)	Requester's Email	Enroll- ment and Revoc- ation	Yes	The email address retrieved from Active Directory of the user account that requested the certificate from the CA, if present.
				Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
\$(re- quester:givenname)	Requester's e) First Name	Enroll- ment and Revoc- ation	Yes	The first name retrieved from Active Directory of the user account that requested the certificate from the CA, if present.
				Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
\$(requester:sn)	Requester's Last Name	Enroll- ment and Revoc- ation	Yes	The last name retrieved from Active Directory of the user account that requested the certificate from the CA, if present.
				Note: This substitutable special text token is only

Variable	Name	Request Type	In Drop- down?	Description
				supported in environments using Active Directory as an identity provider.
\$(re- quester- :displayname)	Requester's Display Name	Enroll- ment and Revoc- ation	Yes	The display name retrieved from Active Directory of the user account that requested the certificate from the CA, if present.
				Note: This substitutable special text token is only supported in environments using Active Directory as an identity provider.
\$(reviewlink)	Review Link	Certificate Collection, Enrollment and Revoc-	Yes	Link pointing to the review page in the Management Portal for the work- flow instance where the person responsible for providing signal input (e.g. approving the request) can go to review the request and provide the input.
		ation		Note: This option is only useful in workflows that contain a step that requires signal input (e.g. requires approval).
\$(RevokeCode)	n/a	Revoc- ation	No	The reason selected at revocation time to explain the revocation as an integer (e.g. 3). See also \$(code). For details on the mapping of numeric revocation codes to revocation strings, refer to the POST /Certificates/Revoke API endpoint (see POST Certificates Revoke in the Keyfactor API Reference Guide).
\$(sans)	Subject	Enroll-	Yes	Subject alternative name(s)

Variable	Name	Request Type	In Drop- down?	Description
	Alternative	ment		contained in the certificate request. There are four possible sources for the SANs that appear here:  • For CSR enrollment, the original SANs included in the CSR.  • Any SANs added through the Keyfactor Command Management Portal. For CSR enrollment, these take the place of the SANs in the CSR if the ATTRIBUTESUBJECTALTNAME2 option is enabled on the CA. See CSR Enrollment on page 136.  • A SAN matching the CN added automatically during enrollment as a result of setting the RFC 2818 compliance flag in the CA configuration. See Adding or Modifying a CA Record on page 355. For PFX enrollment, the user has the option of editing this entry at enrollment time; entry of something is required.  • A SAN matching the CN added automatically by the Keyfactor Command policy module on the CA if the Keyfactor Command RFC 2818 Policy Handler is enabled, if one was not included in

Variable	Name	Request Type	In Drop- down?	Description
				the CSR or added manually. See Installing the Keyfactor CA Policy Module Handlers in the Keyfactor Command Server Installation Guide.
\$(serial)	Serial Number	Certificate Collection and Revocation	Yes	Certificate serial number.
\$(stores)	n/a	Enroll- ment	No	The certificate store(s) to which the certificate will be delivered on issuance.
\$(subdate)	Submission Date	Enroll- ment and Revoc- ation	Yes	Date the workflow was initiated.
\$(template)	Template Name	Certi- ficate Collection and Enroll- ment	Yes	The short name (often the name with no spaces) of the certificate template used to create the certificate request.
\$(thumbprint)	Thumbprint	Certificate Collection and Revocation	Yes	Thumbprint of the certificate.
\$(metadata:Email- Contact)	Email- Contact	Certificate Collection, Enrollment and Revocation	Yes	Example of a custom metadata field. Your custom metadata fields would be referenced similarly (e.g. \$(metadata:AppOwnerFirstName) for metadata field AppOwnerFirstName).

# Using the Workflow Definitions Search Feature

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an *is null* or *is not null* comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

Each query consists of three parts:

# **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

DisplayName	IsPublished
Complete or partial matches with the name of the workflow definition.	The workflow has been published yes/no.
	WorkflowType
Id	The type of workflow (enrollment, revocation, certi-
The Keyfactor Command reference GUID for the	ficateenteredcollection, or certi-
workflow definition.	ficateleftcollection).

# **Comparison Operator**

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Contains (-contains)
- Does not contain (-notcontains)
- Most date and integer fields support:
- Is equal to (-eq)
- Is not equal to (-ne)
- Is less than (-It)
- Is less than or equal to (-le)
- Most Boolean (true/false) fields support:

- Starts with (-startswith)
- Ends with (-endswith)
- Is null (-eq NULL)
- Is not null (-ne NULL)
- Is greater than (-gt)
- Is greater than or equal to (-ge)
- Is null (-eq NULL)
- Is not null (-ne NULL)

- Is equal to (-eq)
- Is not equal to (-ne)

- Is null (-eq NULL)
- Is not null (-ne NULL)

# Comparison Value

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

- Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.
- Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

Figure 195: Simple Workflow Definitions Search

The search results can be sorted by clicking on a column header in the results grid for several of the columns. Click the column header again to reverse the sort order. The grid columns can be arranged in any order desired by click-holding and dragging the header of the column you wish to move. The column widths may be adjusted by click-holding and dragging the line separating two column headers.

#### **Advanced Searches**

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

#### Multiple Criteria

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click **Insert** to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you

click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

#### 2.1.7.2 Workflow Instances

Whether you've chosen to create custom workflow definitions (see Workflow Definitions on page 230) or are relying on the built-in global workflow definitions, all certificate enrollments, renewals, and revocations go through workflow and create workflow instances. Certificate collection additions and removals only go through workflows if you create custom workflows for these actions, as there aren't built-in global workflows for these functions. The workflow instance is the combination of the certificate action and the workflow definition for that action as defined at the time that action took place.

**Example:** You have a custom enrollment workflow definition for the EnterpriseWebServer template. It contains a couple of steps including RequireApproval, which requires approval from at least two PKI admins before a certificate with this template may be issued. The workflow definition has been edited and published a few times and is now at version 3. John enrolls for a certificate using the Management Portal PFX Enrollment option and selects this template. When the enrollment completes, he receives a message indicating that the request is awaiting approval.

Figure 196: PFX Enrollment Complete for a Template Requiring Approval via Workflow

A workflow instance has now been created for his request. Users with appropriate permissions can view the instance in *Workflow Instances*.

Figure 197: View Workflow Instance for a PFX Enrollment

Users with permissions to approve the request can do so through their *My Workflows* page and the *Assigned to Me* tab (see My Workflows on page 325).

After John completes his enrollment and before it is approved, an administrator makes a change to the workflow for the EnterpriseWebServer template and publishes the new version. The current workflow is now at version 4. However, John's request remains outstanding and valid with version 3 of the workflow. Any change made for version 4 of the template will not be reflected in John's request.

The only circumstance under which John's request might complete using version 4 of the workflow definition would be:

- If the administrator observed the suspended workflow (suspended because it is awaiting approvals), knew there was a new version of the workflow, and pro-actively restarted the workflow instance. A workflow instance restarted from a suspended state will always restart (from the beginning) with the currently active version of the workflow definition.
- If the administrator observed the suspended workflow, stopped the workflow knowing it should not be allowed to complete with the workflow definition it was submitted with, made

- a further update to the workflow definition, and then restarted the workflow with the newly updated version of the workflow definition. One common reason to stop and restart rather than just restarting would be to allow time to make changes to the workflow.
- If the original request failed for some reason (e.g. the CA was not responding when the
  final approval was received and the request was submitted to the CA) and the administrator chose to restart the failed request with the currently active version of the workflow definition (the default) rather than the original version of the workflow after resolving
  the reason for the failure.

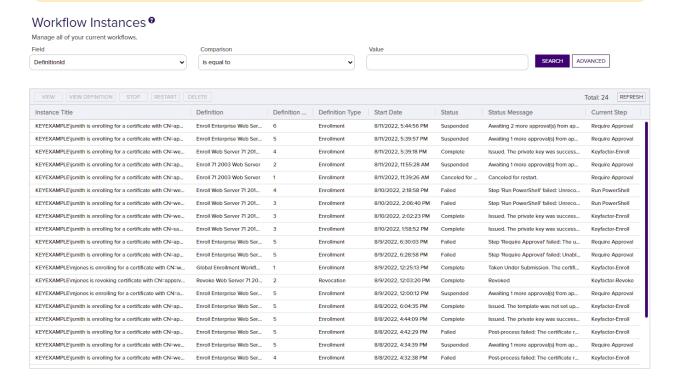

Figure 198: Workflow Instances

**Tip**: Click the help icon (2) next to the page title to open the embedded web copy of the *Keyfactor Command Documentation Suite* to this section.

You can also find the help icon at the top of the page next to the **Log Out** button. From here you can choose to open either the *Keyfactor Command Documentation Suite* at the home page or the *Keyfactor API Endpoint Utility*.

#### **Workflow Instances Operations**

A workflow instance is created for *every* certificate enrollment, renewal, or revocation request you make through the Keyfactor Command Management Portal. The addition and removal of certificates from certificate collections can be configured to flow through workflow as well, but these create workflow instances only if configured. If a given request is made using a workflow definition (see

<u>Workflow Definitions on page 230</u>) that has been configured with steps to require approvals for the request, run a PowerShell script, or make an API request as part of the request flow, you may find yourself on the Workflow Instances page needing to manage the instances.

Workflow instance operations include:

- Viewing a workflow instance to review details of the instance
- Viewing the workflow definition as configured for the particular workflow instance to understand the configuration at the time the instance was initiated
- · Stopping a workflow instance
- Restarting a workflow instance after correcting a failure (e.g. the CA was not responding on an enrollment) or to introduce a different workflow definition
- · Deleting workflow instances to clean house

Depending on the page from which the workflow instance is viewed from, different data will be shown.

#### **Instance Data Details**

#### **Instance Section Data**

Name	Description				
ld	A GUID indicating the Keyfactor Command reference ID for the instance.				
Title	A description for the action taking place in the step. For example:				
	"KEYEXAMPLE\jsmith is enrolling for a certificate with CN=appsrvr12.keyexample.com."				
	Or:				
	"KEYEXAMPLE\mjones is revoking certificate with CN=appsrvr14.keyexample.com."				
Status	The current status message of the workflow instance.				
	For example, for an enrollment that <b>succeeded</b> , the status message might be:				
	Issued. The private key was successfully retained.				
	For a workflow suspended and awaiting approval, the status message might be:				

# Name **Description** Awaiting 2 more approval(s) from approval roles. For an enrollment that could not be submitted because a regular expression rule was not met, the status message might be something like: Pre-process failed: Invalid ST provided: Value must be one of California, Washington, Texas, New York, Illinois or Ohio. For an enrollment that failed due to rejection by the CA, the status message might be: The certificate request failed with the reason '[CA reason]' A workflow that failed at a PowerShell step might include the PowerShell error in the status message: Step 'Run PowerShell' failed: At line:5 char:19 [datetime]\$Date Missing ')' in function parameter list. At line:7 char:1 + ) Unexpected token ')' in expression or statement. Current The display name defined for the workflow instance step at which the instance has paused Step or stopped. For a successfully completed enrollment or revocation workflow, this will be either Keyfactor-Revoke or Keyfactor-Enroll. For a suspended workflow, this will be the

custom step that is awaiting user input to continue the workflow. For a failed workflow, this

will be the step at which the workflow failed.

# Workflow Signal Review

Review and send a workflow signal.

# □ Instance Id d153063e-3753-42f8-af30-a9b2a9e7bd75 Title KEYEXAMPLE\smith is enrolling for a certificate with CN=appsrvr14.keyexample.com. Status Awaiting 1 more approval(s) from approval roles. Current Step Require Approval

Figure 199: Workflow Instance Review

## **Current Data Section**

The data included in this section will vary depending on the request type, the status of the request, and the configuration of the workflow.

#### Enrollment

Name	Description
Subject	The distinguished name of the certificate.
CSR:Raw	The unparsed version of the certificate signing request generated for the certificate request.
CSR: Parsed	The parsed version of the certificate signing request generated for the certificate request. The CSR may include:  Key Length The desired key size for the certificate.  Key Type The desired key encryption for the certificate.  C The country (two characters) of the certificate.  ST The state or province of the certificate.  L The city or locality of the certificate.  OU The organizational unit of the certificate.  O The organization of the certificate.  E The email address of the certificate.

Name	Description
	<ul> <li>CN The common name of the certificate.</li> <li>DNS Name A SAN value containing a DNS name.</li> <li>IP Address A SAN value containing an IP v4 or IP v6 address.</li> <li>RFC822 Name A SAN value containing an email address.</li> <li>Other name:Principal A SAN value containing a user principal name (UPN).</li> </ul>
Additional Attrib- utes	Values for any custom enrollment fields set on the certificate template to supply custom request attributes to the CA during the enrollment process.
CA Certificate	<ul> <li>The certificate information returned from the CA for the certificate that is being requested, including:</li> <li>CA Certificate ID  The ID assigned to the certificate by the CA.</li> <li>CA Request ID  The ID assigned to the certificate request by the CA.</li> <li>Status  The numeric status for the certificate as returned by the CA.</li> <li>Certificate Template  The certificate template used to issue the certificate.</li> <li>Revocation Date  The revocation date for the certificate as returned by the CA, if applicable (generally not for newly enrolled certificates).</li> <li>Revocation Reason  The revocation reason for the certificate as returned by the CA, if applicable (generally not for newly enrolled certificates).</li> <li>Archived Key  A flag indicating whether the certificate is configured for key archival on the CA (true) or not (false).</li> </ul>

Name	Description
CA Certificate Data: Raw	The certificate as returned by the CA in base-64 encoded binary format.
CA Certificate Data: Parsed	<ul> <li>Issued DN The distinguished name of the certificate.</li> <li>Issuer DN The distinguished name of the issuer.</li> <li>Thumbprint The thumbprint of the certificate.</li> <li>Not After The date, in UTC, on which the certificate expires.</li> <li>Not Before The date, in UTC, on which the certificate was issued by the certificate authority.</li> <li>Metadata The metadata fields populated for the certificate.</li> </ul>
CA Certificate Request	The certificate request information returned from the CA for the certificate that is being requested, including:  CA Request ID The ID assigned to the certificate request by the CA.  CSR The certificate signing request for the certificate request as returned by the CA.  Status The status for the certificate as returned by the CA.  Requester Name The requester name on the certificate request as returned by the CA.  Note: This field is populated only if the certificate request fails at the CA level or requires manager approval at the CA level.
Certificate Authority	The certificate authority that will be used to enroll against in <i>host-name\logical name</i> format.
Custom Name	A custom friendly name for the certificate, if entered at enrollment.

Name	Description
Disposition Message	A message about the certificate request.
Wessage	Note: This field is populated only after the certificate request has been submitted to the CA.
Format	The desired output format for the certificate. A value of STORE indicates that the certificate is intended to be delivered into one or more certificate stores.
Include Chain	A flag indicating whether to include the certificate chain in the enrollment response (true) or not (false).
Initiating User Name	The name of the user who initiated the workflow in DOMAIN\username format.
Is PFX	A flag indicating whether the certificate enrollment type that initiated the workflow instance was PFX (true) or CSR (false).
Issuer DN	The distinguished name of the issuer.
Key Retention	A flag indicating whether the private key for the certificate resulting from the enrollment will be retained in Keyfactor Command (true) or not (false).
Key Status	A numeric value indicating the status of the private key retention for the certificate within Keyfactor Command. Possible values are:  • 0—Unknown  • 1—Saved  • 2—Expected  • 3—NoRetention  • 4—Failure  • 5—Temporary
Keyfactor Id	The Keyfactor Command reference ID for the certificate.
Management Job Time	The schedule for the management job to add the certificate to any certificate store(s).
Metadata	Values for the metadata fields that will be associated with the certificate once it is in Keyfactor Command.

Nome	Description	
Name PFX Password Secret Instance	Description  The Keyfactor Command reference ID for the PFX password used to secure the PFX file on download.	
Private Key Converter	An internally used Keyfactor Command field.	
Renewal Certi- ficate	Certificate Id - The Keyfactor Command reference ID of the certificate this certificate replaces on a renewal.	
Renewal Certi- ficate Data: Raw	The certificate that this certificate replaces on a renewal as returned by the CA in base-64 encoded binary format.	
Renewal Certificate Data: Parsed	The certificate details for the certificate that this certificate replaces on a renewal, including:  Issued DN The distinguished name of the certificate.  Issuer DN The distinguished name of the issuer.  Thumbprint The thumbprint of the certificate.  Not After The date, in UTC, on which the certificate expires.  Not Before The date, in UTC, on which the certificate was issued by the certificate authority.  Metadata The metadata fields populated for the certificate.	
SANs: Type	The subject alternate names defined for the certificate. Possible types that can be entered within Keyfactor Command are DNS Name, IPv4 Address, IPv6 Address, User Principal Name, and Email. Within each type is a list of entries for that type shown with a key name of the entry number and the actual value. For example, if you had two DNS SANs, the DNS Name section would look something like:  Entry 1: myfirstsan.keyexample.com Entry 2: mysecondsan.keyexample.com	

Name	Description	
Serial Number	The serial number of the certificate.	
Stores	The certificate stores to which the certificate should be distributed, if applicable.	
Template	The template that was used when requesting the certificate.	
Thumbprint	The thumbprint of the certificate.	
(Custom)	Optional user-generated custom fields returning response data from Power-Shell scripts or REST requests. These will be sorted alphabetically in among the other fields on the page.	

## Revocation

For a revocation, this section may include:

Name	Description
Certificate Authority	The certificate authority that issued the certificate.
Certificate Id	The Keyfactor Command reference ID for the certificate being revoked.
Comment	A freeform reason or comment to explain why the certificate is being revoked.
Delegate	A flag indicating whether delegation was enabled for the certificate authority that issued the certificate at the time revocation was requested (true) or not (false). For more information, see <a href="Authorization Methods Tab on page 368">Authorization Methods Tab on page 368</a> .
Effective Date	The date and time when the certificate will be revoked.
Initiating User Name	The name of the user who initiated the workflow in DOMAIN\\username format.
Operation Start	The time at which the revocation workflow was initiated.
RevokeCode	The specific reason that the certificate is being revoked. Possible values are:  -1—Remove from Hold  -0—Unspecified  -1—Key Compromised  -2—CA Compromised  -3—Affiliation Changed

Name	Description
	<ul> <li>4-Superseded</li> <li>5-Cessation of Operation</li> <li>6-Certificate Hold</li> <li>7-Remove from CRL. Only valid in the case that a cert is already on a CRL in a manner that it can be removed, such as Certificate Hold.</li> </ul>
Serial Number	The serial number of the certificate being revoked.
Thumbprint	The thumbprint of the certificate being revoked.
(Custom)	Optional user-generated custom fields returning response data from PowerShell scripts or REST requests. These will be sorted alphabetically in among the other fields on the page.

## **Certificate Entered Collection and Certificate Left Collection**

For a certificate that entered or left a certificate collection, this section generally includes:

Name	Description
Certificate Id	The Keyfactor Command reference ID for the certificate added to or removed from the certificate collection.
Initiating User Name	The name of the user who initiated the workflow—generally <i>Timer Service</i> in this case.

#### Operations

## Viewing a Workflow Instance

Tip: The following permissions (see Security Roles and Claims in the Keyfactor Command Reference Guide) are required to use this feature: Workflows > Instances > Read

To view a workflow instance:

- 1. In the Management Portal, browse to Workflow > Workflow Instances.
- 2. On the Workflow Instances page, double-click or click View from either the top or right click menu.
- 3. The Instance Review dialog includes the following information:.

Figure 200: View a Workflow Instance

4. Click Close to close the viewer.

## Viewing a Workflow Instance Definition

Tip: The following permissions (see Security Roles and Claims in the Keyfactor Command Reference Guide) are required to use this feature:

Workflows > Instances > Read Workflows > Definitions > Read

The workflow definition as it existed at the time a particular workflow instance was generated may not necessarily match the current workflow definition. Using the Workflow Definition option on the Workflow Instances page, you can view the workflow definition for the selected instance as it was at the time the instance was initiated using the workflow workspace.

To view a workflow instance definition:

- 1. In the Management Portal, browse to Workflow > Workflow Instances.
- 2. On the Workflow Instances page, select a workflow instance and click **View Definition** from either the top or right-click menu.
- 3. A read-only copy of the workflow definition at the time the instance was initiated will open in the workflow definition workspace. For information about using the workflow definition workspace, see Adding, Copying or Modifying a Workflow Definition on page 237.

## Stopping a Workflow Instance

If a workflow instance has been initiated in error or with a workflow definition that is not configured correctly, you have the option to stop the workflow instance.

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Workflows > Instances > Read Workflows > Instances > Manage

To stop a workflow instance:

- 1. In the Management Portal, browse to Workflow > Workflow Instances.
- 2. On the Workflow Instances page, select a workflow instance and click **Stop** from either the top or right-click menu.
- 3. On the Confirm Operation alert, click **OK** to confirm or **Cancel** to cancel the operation.

**Note**: Only workflow instances with a Status of *Suspended* can be stopped.

#### **Restarting a Workflow Instance**

If a workflow instance has failed or been stopped to correct an issue, you may restart it to reinitialize the request after correcting whatever issue caused the failure (e.g. a PowerShell script failed or a CA was not responding on enrollment). You may also choose to use restart if a workflow instance was initiated with a workflow definition that had an incorrect definition that can easily be corrected—for example, the definition requires approval from just one user and that user is no longer available. In this case, you can update the definition, republish it, and then restart the workflow with the latest published version.

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Workflows > Definitions > Read

Workflows > Instances > Read

Workflows > Instances > Manage

When you restart a workflow instance, it starts over from the beginning, not from the failure point.

To restart a workflow instance:

- 1. In the Management Portal, browse to *Workflow > Workflow Instances*.
- 2. On the Workflow Instances page, select a workflow instance and click **Restart** from either the top or right-click menu.
- 3. On the Confirm Operation alert, click **OK** to confirm or **Cancel** to cancel the operation.

Note: Only workflow instances with a Status of Failed or Suspended can be restarted.

After restarting a workflow instance, you can view any differences between the original instance and the newly restarted instance by looking at the audit log record (see <u>Audit Log Operations on page 723</u>) for the workflow instance restart. The Related Entries in the audit log record do not include the original workflow instance that failed since restarting a workflow instance generates a new workflow instance.

**Tip:** If user John Smith restarts a workflow instance that was originally started by user Martha Jones, the audit log message for this will look something like:

"The user 'KEYEXAMPLE\jsmith' restarted workflow instance, 'KEYEXAMPLE\mjones is enrolling for a certificate with CN=appsrvr12.keyexample.com.'"

In a scenario like this, the user listed at the top of the audit log details will be the user who restarted the instance, not the user who originally started the request.

Figure 201: View an Audit Log Entry for a Restarted Workflow Instance

## **Deleting a Workflow Instance**

If a workflow instance has failed, you may wish to remove the failed instance from the grid.

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Workflows > Instances > Read Workflows > Instances > Manage

To delete a workflow instance:

- 1. In the Management Portal, browse to Workflow > Workflow Instances.
- 2. On the Workflow Instances page, select a workflow instance and click **Delete** from either the top or right-click menu.
- 3. On the Confirm Operation alert, click **OK** to confirm or **Cancel** to cancel the operation.

An audit log entry is created when you delete a workflow instance (see <u>Audit Log on page 718</u>). Instances deleted as the result of system action (e.g. purging old records) are not audited.

#### Using the Workflow Instances Search Feature

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an *is null* or *is not null* comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

Each query consists of three parts:

#### **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

DefinitionId	StartDate
The Keyfactor Command reference GUID for the workflow definition.	The date and time when an instance was initiated.
	Status
Id  The Keyfactor Command reference GUID for the	Status matches or doesn't match the referenced value. Supported statuses are:
workflow instance.	• Unknown
InitiatingUserName	<ul><li>Running</li><li>Suspended</li></ul>
Complete or partial matches with the name of the	• Failed
user who initiated the workflow instance in DOMAIN\username format for Active Directory authentication or username for Keyfactor Identity Provider.	<ul><li>Complete</li><li>Rejected</li><li>CanceledforRestart</li></ul>
LastModified	Title

The date and time on which an initiated instance

was last updated. The instance is updated each

time a step in the workflow is completed, when

Complete or partial matches with the description

for the action taking place in the workflow instance

step. The values in the title will vary and generally

signals are received for a step that accepts signals (e.g. a requires approval step), or when an instance is stopped or restarted.

include the user initiating the request and the CN of the certificate or certificate request involved.

#### WorkflowType

The type of workflow (enrollment, revocation, certificateenteredcollection, or certificateleftcollection).

## **Comparison Operator**

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Contains (-contains)
- Does not contain (-notcontains)
- Most date and integer fields support:
- Is equal to (-eq)
- Is not equal to (-ne)
- Is less than (-It)
- Is less than or equal to (-le)
- Most Boolean (true/false) fields support:
- Is equal to (-eq)
- Is not equal to (-ne)

- Starts with (-startswith)
- Ends with (-endswith)
- Is null (-eq NULL)
- Is not null (-ne NULL)
- Is greater than (-gt)
- Is greater than or equal to (-ge)
- Is null (-eq NULL)
- Is not null (-ne NULL)
- Is null (-eq NULL)
- Is not null (-ne NULL)

## Comparison Value

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

- Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.
- Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

Figure 202: Simple Workflow Instance Search

The search results can be sorted by clicking on a column header in the results grid for several of the columns. Click the column header again to reverse the sort order. The grid columns can be arranged in any order desired by click-holding and dragging the header of the column you wish to move. The column widths may be adjusted by click-holding and dragging the line separating two column headers.

#### **Advanced Searches**

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

#### **Multiple Criteria**

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click **Insert** to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template

referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the Clear button.

#### 2.1.7.3 My Workflows

When a workflow is initiated by a certificate enrollment, renewal, revocation request, or automated task (for workflows of types Certificate Entered Collection and Certificate left Collection), that workflow instance may appear in as many as two places:

- If the workflow definition for the instance requires signal input (e.g. approval), every Keyfactor Command user who holds a security role that has been defined in the workflow definition as allowed to send signals to the workflow (see Workflow Definitions on page 230) will see that instance appear on the Assigned to Me tab of the My Workflows page. The users can provide signal input (e.g. approve or deny the request) from here. The workflow does not necessarily need to receive signal input from all these users, depending on how many users with this role there are and how many users were required to provide signal input in the workflow definition. Once the workflow instance is complete, it disappears from the Assigned to Me tab for all users.
- The user who initiated the workflow (e.g. by beginning a certificate enrollment or revoking a certificate) will see that instance appear on the Created by Me tab of the My Workflows page. When the workflow instance is complete, it will still appear on the Created by Me tab and be searchable.

Tip: The following permissions (see Security Roles and Claims in the Keyfactor Command Reference Guide) are required to use this feature:

Workflows > Instances > Read OR Workflows > Instances > Read > Mine

Users with only Read > Mine will only be able to see the Created by Me or Assigned to Me tab, respectively. A user with Read will be able to see both tabs.

**Example:** The enrollment workflow definition for the EnterpriseWebServer template requires two approvals from users with the Enrollment Approvers security role. There are five users with this role: Anne, Charles, John, Mary, and Sam. Martha enrolls for a certificate using the Keyfactor Command Management Portal PFX Enrollment method and the EnterpriseWebServer template.

Figure 203: Workflows Assigned to Mary

The new workflow instance appears on the Assigned to Me tab of all users with the Enrollment Approvers role and on Martha's Created by Me tab. Approvers Mary and John approve the instance on their respective Assigned to Me tab and the certificate is issued. The workflow instance disappears from the Assigned to Me tab for all users. It's still visible on the main Workflow Instances page and on Martha's Created by Me tab as a completed instance.

**Note:** A locking conflict may occur if two (or more) users attempt to provide input to a workflow instance (e.g. approve a request) at exactly the same time. If this happens, input from only one of the users will be reflected in the Management Portal, and the workflow instance will not be moved along to the next step if it should have been with input from the two users. The other input is still accepted, however, and there is a scheduled task that runs daily and attempts to continue all suspended workflows that may be eligible to continue but have not done so due to locking conflicts.

**Tip**: Click the help icon (2) next to the page title to open the embedded web copy of the *Keyfactor Command Documentation Suite* to this section.

You can also find the help icon at the top of the page next to the **Log Out** button. From here you can choose to open either the *Keyfactor Command Documentation Suite* at the home page or the *Keyfactor API Endpoint Utility*.

#### **Workflows Assigned to Me Operations**

Only workflow instances that are in a Suspended state and that the current user has permissions to submit signals for (e.g. approve or deny) appear on the Assigned to Me tab of the My Workflows page. Once the user submits a signal to a workflow instance on this page, it is removed from the page.

**Note**: If a workflow instance is initiated for a workflow definition that has more than one step requiring input (signals), a user can only provide that input (e.g. approve or deny a require approval request) at the step in the workflow instance where the workflow instance was

suspended pending input. The user cannot jump ahead and provide input for future steps in the workflow that have not yet occurred.

Tip: The following permissions (see Security Roles and Claims in the Keyfactor Command Reference Guide) are required to use this feature:

Workflows > Instances > Read > Mine

Or:

Workflows > Instances > Read

To review a workflow instance and potentially submit a signal for it:

- 1. In the Management Portal, browse to *Workflow > My Workflows*.
- 2. On the Assigned to Me tab of the My Workflows page, double-click or click Review from either the top or right click menu.
- 3. On the Workflow Signal Review page, review the information in the instance before submitting a signal for the request. Information on the review page includes:

Name	Description	
ld	A GUID indicating the Keyfactor Command reference ID for the instance.	
Title	A description for the action taking place in the step. For example:	
	"KEYEXAMPLE\jsmith is enrolling for a certificate with CN=appsrvr12.keyexample.com."	
	Or:	
	"KEYEXAMPLE\mjones is revoking certificate with CN=appsrvr14.keyexample.com."	
Status	The current status message of the workflow instance.	
	For a workflow suspended and awaiting approval, the status message might be:	
	Awaiting 2 more approval(s) from approval roles.	
Current Step	The display name defined for the workflow instance step at which the instance has paused. For a suspended workflow, this will be the custom step that is awaiting user input to continue the workflow.	

# Workflow Signal Review

Review and send a workflow signal.

#### ☐ Instance

ld	d153063e-3753-42f8-af30-a9b2a9e7bd75
Title	KEYEXAMPLE\jsmith is enrolling for a certificate with CN=appsrvr14.keyexample.com.
Status	Awaiting 1 more approval(s) from approval roles.
Current Step	Require Approval

Figure 204: Workflow Instance Review

The data included in this section will vary depending on the request type and the configuration of the workflow.

#### Enrollment

Name	Description
Subject	The distinguished name of the certificate.
CSR:Raw	The unparsed version of the certificate signing request generated for the certificate request.
CSR: Parsed	The parsed version of the certificate signing request generated for the certificate request. The CSR may include:  • Key Length The desired key size for the certificate.  • Key Type The desired key encryption for the certificate.  • C The country (two characters) of the certificate.  • ST The state or province of the certificate.  • L The city or locality of the certificate.  • OU The organizational unit of the certificate.  • O The organization of the certificate.

Name	Description	
	<ul> <li>The email address of the certificate.</li> <li>CN         The common name of the certificate. </li> <li>DNS Name         A SAN value containing a DNS name. </li> <li>IP Address         A SAN value containing an IP v4 or IP v6 address. </li> <li>RFC822 Name         A SAN value containing an email address. </li> <li>Other name:Principal         A SAN value containing a user principal name (UPN). </li> </ul>	
Additional Attrib- utes	Values for any custom enrollment fields set on the certificate template to supply custom request attributes to the CA during the enrollment process.	
Certificate Authority	The certificate authority that will be used to enroll against in <i>host-name\logical name</i> format.	
Custom Name	A custom friendly name for the certificate, if entered at enrollment.	
Format	The desired output format for the certificate. A value of STORE indicates that the certificate is intended to be delivered into one or more certificate stores.	
Include Chain	A flag indicating whether to include the certificate chain in the enrollment response (true) or not (false).	
Initiating User Name	The name of the user who initiated the workflow in DOMAIN\username format.	
Is PFX	A flag indicating whether the certificate enrollment type that initiated the workflow instance was PFX (true) or CSR (false).	
Key Retention	A flag indicating whether the private key for the certificate resulting from the enrollment will be retained in Keyfactor Command (true) or not (false).	
Management Job Time	The schedule for the management job to add the certificate to any certificate store(s).	

Name	Description	
Metadata	Values for the metadata fields that will be associated with the certificate once it is in Keyfactor Command.	
PFX Password Secret Instance Id	The Keyfactor Command reference ID for the PFX password used to secure the PFX file on download.	
Renewal Certi- ficate	Certificate Id - The Keyfactor Command reference ID of the certificate this certificate replaces on a renewal.	
Renewal Certi- ficate Data: Raw	The certificate that this certificate replaces on a renewal as returned by the CA in base-64 encoded binary format.	
Renewal Certificate Data: Parsed	The certificate details for the certificate that this certificate replaces on a renewal, including:  Issued DN The distinguished name of the certificate.  Issuer DN The distinguished name of the issuer.  Thumbprint The thumbprint of the certificate.  Not After The date, in UTC, on which the certificate expires.  Not Before The date, in UTC, on which the certificate was issued by the certificate authority.  Metadata The metadata fields populated for the certificate.	
SANs: Type	The subject alternate names defined for the certificate. Possible types that can be entered within Keyfactor Command are DNS Name, IPv4 Address, IPv6 Address, User Principal Name, and Email. Within each type is a list of entries for that type shown with a key name of the entry number and the actual value. For example, if you had two DNS SANs, the DNS Name section would look something like:  Entry 1: myfirstsan.keyexample.com Entry 2: mysecondsan.keyexample.com	

Name	Description	
Stores	The certificate stores to which the certificate should be distributed, if applicable.	
Template	The template that was used when requesting the certificate.	
(Custom)	Optional user-generated custom fields returning response data from PowerShell scripts or REST requests. These will be sorted alphabetically in among the other fields on the page.	

## Revocation

For a revocation, this section may include:

Name	Description
Certificate Authority	The certificate authority that issued the certificate.
Certificate Id	The Keyfactor Command reference ID for the certificate being revoked.
Comment	A freeform reason or comment to explain why the certificate is being revoked.
Delegate	A flag indicating whether delegation was enabled for the certificate authority that issued the certificate at the time revocation was requested (true) or not (false). For more information, see <a href="Authorization Methods Tab on page 368">Authorization Methods Tab on page 368</a> .
Effective Date	The date and time when the certificate will be revoked.
Initiating User Name	The name of the user who initiated the workflow in DOMAIN\\username format.
Operation Start	The time at which the revocation workflow was initiated.
RevokeCode	The specific reason that the certificate is being revoked. Possible values are:  -1—Remove from Hold  -0—Unspecified  -1—Key Compromised  -2—CA Compromised  -3—Affiliation Changed  -4—Superseded  -5—Cessation of Operation

Name	Description
	<ul> <li>6—Certificate Hold</li> <li>7—Remove from CRL. Only valid in the case that a cert is already on a CRL in a manner that it can be removed, such as Certificate Hold.</li> </ul>
Serial Number	The serial number of the certificate being revoked.
Thumbprint	The thumbprint of the certificate being revoked.
(Custom)	Optional user-generated custom fields returning response data from Power-Shell scripts or REST requests. These will be sorted alphabetically in among the other fields on the page.

## **Certificate Entered Collection and Certificate Left Collection**

For a certificate that entered or left a certificate collection, this section generally includes:

Name	Description
Certificate Id	The Keyfactor Command reference ID for the certificate added to or removed from the certificate collection.
Initiating User Name	The name of the user who initiated the workflow—generally <i>Timer Service</i> in this case.

## Signal Input

In the Signal Input section of the page, you can submit one or more signals for the step. For the built-in require approval workflow step type, this is where you send an approval or denial for the request along with a comment about the approval or denial.

## Workflow Signal Review

Review and send a workflow signal.

Figure 205: Approve or Deny a Workflow Instance

A custom workflow step requiring signal input may have more than one signal type to select from in the dropdown, may have input fields to submit data with the signal, and will likely have buttons with labels other than *Deny* or *Approve*.

4. At the bottom of the Workflow Signal Review page in the Signal Input section, select an option in the Signal Type dropdown, enter any required signal data, and click an appropriate signal button to submit the signal. For the built-in require approval workflow step type, select *ApprovalStatus* in the dropdown (there is only one choice), enter an optional **Comment** (the maximum comment length is 500 characters), and click either **Approve** to add your approval to the workflow or **Deny** to deny the workflow instance.

Tip: If you reference the approve/deny comments using the \$(approvalsignalcmnts) token, the included comments will vary depending on where you use the token. If you use the token in an email message within a require approval step, only comments from that require approval step will be included. If you use the token in a separate email step within the same workflow, all comments from any require approval steps within the workflow will be included.

**Important:** Comments entered when approving or denying a built-in require approval workflow step can be included in emails delivered either as part of the require approval step or in subsequent steps within the workflow, but they are not retained for future reference. If you would like to retain them for future reference, use a workflow step that copies the comment(s) to a metadata field (see <u>Use Custom PowerShell on page 282</u>).

5. On the Confirm Operation alert, click **OK** to confirm or **Cancel** to cancel the operation.

**Note**: The workflow definition may require more than one approval to be completed and so may not be immediately completed when you click Approve. However, a single denial is enough to reject the workflow instance.

An audit log entry is created when you provide input to a workflow instance (see <u>Audit Log on</u> page 718).

#### Using the Workflow Assigned to Me Search Feature

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an *is null* or *is not null* comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

Each query consists of three parts:

#### **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

DefinitionId	StartDate
Complete or partial matches with the Keyfactor Command reference GUID of the workflow <i>definition</i> .	The date and time when an instance was initiated.
Id	Status
Complete or partial matches with the Keyfactor Command reference GUID of the workflow instance.	Status matches or doesn't match the referenced value. Supported statuses are:  • Unknown  • Running  • Suspended  • Failed
	• Complete

#### InitiatingUserName

Complete or partial matches with the name of the user who initiated the workflow instance in DOMAIN\username format for Active Directory authentication or username for Keyfactor Identity Provider.

#### LastModified

The date and time on which an initiated instance was last updated. The instance is updated each time a step in the workflow is completed, when signals are received for a step that accepts signals (e.g. a requires approval step), or when an instance is stopped or restarted.

- Rejected
- CanceledforRestart

#### Title

Complete or partial matches with the description for the action taking place in the workflow instance step. The values in the title will vary and generally include the user initiating the request and the CN of the certificate or certificate request involved.

#### WorkflowType

The type of workflow (enrollment, revocation, certificateenteredcollection, or certificateleftcollection).

## **Comparison Operator**

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Contains (-contains)
- Does not contain (-notcontains)
- Maatalata and internal fields accomment
- Most date and integer fields support:
- Is equal to (-eq)
- Is not equal to (-ne)
- Is less than (-lt)
- Is less than or equal to (-le)

- Starts with (-startswith)
- Ends with (-endswith)
- Is null (-eq NULL)
- Is not null (-ne NULL)
- Is greater than (-gt)
- Is greater than or equal to (-ge)
- Is null (-eq NULL)
- Is not null (-ne NULL)

#### Most Boolean (true/false) fields support:

- Is equal to (-eq)
- Is not equal to (-ne)

- Is null (-eq NULL)
- Is not null (-ne NULL)

## **Comparison Value**

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only

support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

- Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.
- Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

Figure 206: Simple Workflows Assigned to Me Search

The search results can be sorted by clicking on a column header in the results grid. Only the Instance Title column sortable. Click the column header again to reverse the sort order. The grid columns can be arranged in any order desired by click-holding and dragging the header of the column you wish to move. The column widths may be adjusted by click-holding and dragging the line separating two column headers.

#### **Advanced Searches**

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

#### **Multiple Criteria**

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click **Insert** to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

## **Workflows Created by Me Operations**

On the Created by Me tab of the My Workflows page you can view all the workflows that the current user initiated.

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Workflows > Instances > Read > Mine

Or:

Workflows > Instances > Read

To view details of a workflow instance:

- 1. In the Management Portal, browse to Workflow > My Workflows.
- 2. On the Created by Me tab of the My Workflows page, double-click or click **View** from either the top or right click menu.
- 3. On the Workflow Signal Review page, review the information in the instance. Information on the review page includes:

Name	Description
ld	A GUID indicating the Keyfactor Command reference ID for the instance.
Title A o	A description for the action taking place in the step. For example:
	"KEYEXAMPLE\jsmith is enrolling for a certificate with CN=appsrvr12.keyexample.com."
	Or:
	"KEYEXAMPLE\mjones is revoking certificate with CN=appsrvr14.keyexample.com."
Status	The current status message of the workflow instance.
	For example, for an enrollment that <b>succeeded</b> , the status message might be:
	Issued. The private key was successfully retained.

# Name **Description** For a workflow suspended and awaiting approval, the status message might be: Awaiting 2 more approval(s) from approval roles. For an enrollment that could not be submitted because a regular expression rule was not met, the status message might be something like: Pre-process failed: Invalid ST provided: Value must be one of California, Washington, Texas, New York, Illinois or Ohio. For an enrollment that failed due to rejection by the CA, the status message might be: The certificate request failed with the reason '[CA reason]' A workflow that failed at a PowerShell step might include the PowerShell error in the status message: Step 'Run PowerShell' failed: At line:5 char:19 [datetime]\$Date Missing ')' in function parameter list. At line:7 char:1 + ) + ~ Unexpected token ')' in expression or statement. Current The display name defined for the workflow instance step at which the instance has Step paused or stopped. For a successfully completed enrollment or revocation workflow, this will be either Keyfactor-Revoke or Keyfactor-Enroll. For a suspended workflow, this will be the custom step that is awaiting user input to continue the workflow. For a failed workflow, this will be the step at which the workflow failed.

# Workflow Signal Review

Review and send a workflow signal.

# □ Instance Id d153063e-3753-42f8-af30-a9b2a9e7bd75 Title KEYEXAMPLE\smith is enrolling for a certificate with CN=appsrvr14.keyexample.com. Status Awaiting 1 more approval(s) from approval roles. Current Step Require Approval

Figure 207: Workflow Instance Review

The data included in this section will vary depending on the request type, the status of the request, and the configuration of the workflow.

#### Enrollment

Name	Description
Subject	The distinguished name of the certificate.
CSR:Raw	The unparsed version of the certificate signing request generated for the certificate request.
CSR: Parsed	The parsed version of the certificate signing request generated for the certificate request. The CSR may include:  Key Length The desired key size for the certificate.  Key Type The desired key encryption for the certificate.  C The country (two characters) of the certificate.  ST The state or province of the certificate.  L The city or locality of the certificate.  OU The organizational unit of the certificate.  O The organization of the certificate.  E The email address of the certificate.

Name	Description
	<ul> <li>CN The common name of the certificate.</li> <li>DNS Name A SAN value containing a DNS name.</li> <li>IP Address A SAN value containing an IP v4 or IP v6 address.</li> <li>RFC822 Name A SAN value containing an email address.</li> <li>Other name:Principal A SAN value containing a user principal name (UPN).</li> </ul>
Additional Attrib- utes	Values for any custom enrollment fields set on the certificate template to supply custom request attributes to the CA during the enrollment process.
CA Certificate	The certificate information returned from the CA for the certificate that is being requested, including:  CA Certificate ID The ID assigned to the certificate by the CA.  CA Request ID The ID assigned to the certificate request by the CA.  Status The numeric status for the certificate as returned by the CA.  Certificate Template The certificate template used to issue the certificate.  Revocation Date The revocation date for the certificate as returned by the CA, if applicable (generally not for newly enrolled certificates).  Revocation Reason The revocation reason for the certificate as returned by the CA, if applicable (generally not for newly enrolled certificates).  Archived Key A flag indicating whether the certificate is configured for key archival on the CA (true) or not (false).  Note: This field is populated only after the certificate has been issued by the CA.

Name	Description
CA Certificate Data: Raw	The certificate as returned by the CA in base-64 encoded binary format.
CA Certificate Data: Parsed	<ul> <li>Issued DN The distinguished name of the certificate.</li> <li>Issuer DN The distinguished name of the issuer.</li> <li>Thumbprint The thumbprint of the certificate.</li> <li>Not After The date, in UTC, on which the certificate expires.</li> <li>Not Before The date, in UTC, on which the certificate was issued by the certificate authority.</li> <li>Metadata The metadata fields populated for the certificate.</li> </ul>
CA Certificate Request	The certificate request information returned from the CA for the certificate that is being requested, including:  CA Request ID The ID assigned to the certificate request by the CA.  CSR The certificate signing request for the certificate request as returned by the CA.  Status The status for the certificate as returned by the CA.  Requester Name The requester name on the certificate request as returned by the CA.  Note: This field is populated only if the certificate request fails at the CA level or requires manager approval at the CA level.
Certificate Authority	The certificate authority that will be used to enroll against in host-name\logical name format.
Custom Name	A custom friendly name for the certificate, if entered at enrollment.

Name	Description
Disposition Message	A message about the certificate request.
	Note: This field is populated only after the certificate request has been submitted to the CA.
Format	The desired output format for the certificate. A value of STORE indicates that the certificate is intended to be delivered into one or more certificate stores.
Include Chain	A flag indicating whether to include the certificate chain in the enrollment response (true) or not (false).
Initiating User Name	The name of the user who initiated the workflow in DOMAIN\username format.
Is PFX	A flag indicating whether the certificate enrollment type that initiated the workflow instance was PFX (true) or CSR (false).
Issuer DN	The distinguished name of the issuer.
Key Retention	A flag indicating whether the private key for the certificate resulting from the enrollment will be retained in Keyfactor Command (true) or not (false).
Key Status	A numeric value indicating the status of the private key retention for the certificate within Keyfactor Command. Possible values are:  • 0—Unknown  • 1—Saved  • 2—Expected  • 3—NoRetention  • 4—Failure  • 5—Temporary
Keyfactor Id	The Keyfactor Command reference ID for the certificate.
Management Job Time	The schedule for the management job to add the certificate to any certificate store(s).
Metadata	Values for the metadata fields that will be associated with the certificate once it is in Keyfactor Command.
PFX Password	The Keyfactor Command reference ID for the PFX password used to secure

Name	Description	
Secret Instance	the PFX file on download.	
Private Key Converter	An internally used Keyfactor Command field.	
Renewal Certi- ficate	Certificate Id - The Keyfactor Command reference ID of the certificate this certificate replaces on a renewal.	
Renewal Certi- ficate Data: Raw	The certificate that this certificate replaces on a renewal as returned by the CA in base-64 encoded binary format.	
Renewal Certificate Data: Parsed	The certificate details for the certificate that this certificate replaces on a renewal, including:  Issued DN The distinguished name of the certificate.  Issuer DN The distinguished name of the issuer.  Thumbprint The thumbprint of the certificate.  Not After The date, in UTC, on which the certificate expires.  Not Before The date, in UTC, on which the certificate was issued by the certificate authority.  Metadata The metadata fields populated for the certificate.	
SANs: Type	The subject alternate names defined for the certificate. Possible types that can be entered within Keyfactor Command are DNS Name, IPv4 Address, IPv6 Address, User Principal Name, and Email. Within each type is a list of entries for that type shown with a key name of the entry number and the actual value. For example, if you had two DNS SANs, the DNS Name section would look something like:  Entry 1: myfirstsan.keyexample.com Entry 2: mysecondsan.keyexample.com	

Name	Description	
Serial Number	The serial number of the certificate.	
Stores	The certificate stores to which the certificate should be distributed, if applicable.	
Template	The template that was used when requesting the certificate.	
Thumbprint	The thumbprint of the certificate.	
(Custom)	Optional user-generated custom fields returning response data from Power-Shell scripts or REST requests. These will be sorted alphabetically in among the other fields on the page.	

## Revocation

For a revocation, this section may include:

Name	Description
Certificate Authority	The certificate authority that issued the certificate.
Certificate Id	The Keyfactor Command reference ID for the certificate being revoked.
Comment	A freeform reason or comment to explain why the certificate is being revoked.
Delegate	A flag indicating whether delegation was enabled for the certificate authority that issued the certificate at the time revocation was requested (true) or not (false). For more information, see <a href="Authorization Methods Tab on page 368">Authorization Methods Tab on page 368</a> .
Effective Date	The date and time when the certificate will be revoked.
Initiating User Name	The name of the user who initiated the workflow in DOMAIN\\username format.
Operation Start	The time at which the revocation workflow was initiated.
RevokeCode	The specific reason that the certificate is being revoked. Possible values are:  -1—Remove from Hold  - 0—Unspecified  - 1—Key Compromised  - 2—CA Compromised

Name	Description
	3—Affiliation Changed
	• 4—Superseded
	5—Cessation of Operation
	6-Certificate Hold
	<ul> <li>7—Remove from CRL. Only valid in the case that a cert is already on a CRL in a manner that it can be removed, such as Certificate Hold.</li> </ul>
Serial Number	The serial number of the certificate being revoked.
Thumbprint	The thumbprint of the certificate being revoked.
(Custom)	Optional user-generated custom fields returning response data from PowerShell scripts or REST requests. These will be sorted alphabetically in among the other fields on the page.

# **Certificate Entered Collection and Certificate Left Collection**

For a certificate that entered or left a certificate collection, this section generally includes:

Name	Description
Certificate Id	The Keyfactor Command reference ID for the certificate added to or removed from the certificate collection.
Initiating User Name	The name of the user who initiated the workflow—generally <i>Timer Service</i> in this case.

Figure 208: View Details for the Workflow Instance

4. Click Close to close the viewer.

#### Using the Workflow Created by Me Search Feature

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an *is null* or *is not null* comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

Each query consists of three parts:

#### **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

#### DefinitionId

Complete or partial matches with the Keyfactor Command reference GUID of the workflow *definition*.

Id

Complete or partial matches with the Keyfactor Command reference GUID of the workflow *instance*.

## InitiatingUserName

Complete or partial matches with the name of the user who initiated the workflow instance in DOMAIN\username format for Active Directory authentication or username for Keyfactor Identity Provider.

#### LastModified

The date and time on which an initiated instance was last updated. The instance is updated each time a step in the workflow is completed, when signals are received for a step that accepts signals (e.g. a requires approval step), or when an instance is stopped or restarted.

#### StartDate

The date and time when an instance was initiated.

#### Status

Status matches or doesn't match the referenced value. Supported statuses are:

- Unknown
- Running
- Suspended
- Failed
- Complete
- Rejected
- CanceledforRestart

#### Title

Complete or partial matches with the description for the action taking place in the workflow instance step. The values in the title will vary and generally include the user initiating the request and the CN of the certificate or certificate request involved.

#### WorkflowType

The type of workflow (enrollment, revocation, certificateenteredcollection, or certificateleftcollection).

## **Comparison Operator**

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Contains (-contains)
- Does not contain (-notcontains)

Most date and integer fields support:

- Starts with (-startswith)
- Ends with (-endswith)
- Is null (-eq NULL)
- Is not null (-ne NULL)

- Is equal to (-eq)
- Is not equal to (-ne)
- Is less than (-It)
- Is less than or equal to (-le)

- Is greater than (-gt)
- Is greater than or equal to (-ge)
- Is null (-eq NULL)
- Is not null (-ne NULL)

Most Boolean (true/false) fields support:

- Is equal to (-eq)
- Is not equal to (-ne)

- Is null (-eq NULL)
- Is not null (-ne NULL)

## Comparison Value

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

- Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.
- Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

Figure 209: Simple Workflows Created by Me Search

The search results can be sorted by clicking on a column header in the results grid. Only the Instance Title column sortable. Click the column header again to reverse the sort order. The grid columns can be arranged in any order desired by click-holding and dragging the header of the column you wish to move. The column widths may be adjusted by click-holding and dragging the line separating two column headers.

### **Advanced Searches**

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

## **Multiple Criteria**

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click **Insert** to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

## 2.1.8 Locations

The options available in the Locations section of the Management Portal are:

- <u>Certificate Authorities on the next page</u> Import CAs from Active Directory and/or define CAs, configure synchronization and monitoring tasks for them, set authorization methods and configure enrollment details.
- Certificate Templates on page 380
   Import certificate templates from Active Directory or EJBCA, view certificates, and configure template-specific enrollment details such as: enrollment fields, authorization methods, metadata, template regular expressions, enrollment defaults and policies. Also, set system-wide template enrollment regular expressions, enrollment defaults and policies.
- Certificate Stores on page 409
   Configure paths to certificate stores on multiple machines and devices in the environment, group them into containers for organization, and configure inventory schedules to synchronize the certificates in the stores to Keyfactor Command, and view certificate inventory.
- SSL Discovery on page 454
   Configure SSL endpoint groups on which to run discovery and monitoring jobs and then import certificates from the endpoints for monitoring, reporting and alerting purposes. Define orchestrator pools and view scan results.

#### 2.1.8.1 Certificate Authorities

Your Microsoft and EJBCA certificate authorities (CAs) are defined in the Management Portal to support synchronization to the Keyfactor Command database and support enrollment. Microsoft CAs in the local forest in which Keyfactor Command is installed or in a forest in a two-way trust with this forest may be imported from Active Directory or manually configured. Other Microsoft CAs and EJBCA CAs need to be manually configured. During initial provisioning, any domain-joined Microsoft CAs in the primary Active Directory forest will be imported automatically by the Keyfactor Command configuration wizard.

**Important:** In order for CAs to successfully synchronize to the Keyfactor Command database and perform other functions (e.g. enrollment), the service account under which Keyfactor Command is making the request to the CA must be granted appropriate permission to the CA database as per *Grant the Keyfactor Command Users and Service Account(s) Permissions on the CAs* in the *Keyfactor Command Server Installation Guide*.

CAs that need to be added manually include:

- A domain-joined enterprise or standalone Microsoft CA in a forest with a one-way trust (either direction) with the forest in which Keyfactor Command is installed
- A domain-joined enterprise or standalone Microsoft CA in a forest that has no trust with the forest in which Keyfactor Command is installed
- An EJBCA CA
- A non-domain-joined standalone Microsoft CA
- A Keyfactor CA gateway in the forest in which Keyfactor Command is installed that has not been registered in Active Directory

The CA gateways are used to access cloud certificate providers (e.g. Entrust) or to support Microsoft or EJBCA CAs in remote or cloud environments (e.g. the Cross-Forest Gateway).

**Note**: Keyfactor CA gateways are not supported in any configuration other than in the same forest in which Keyfactor Command is installed.

- An on-premise Microsoft CA accessed via the Keyfactor CA Management Gateway using a managed instance of Keyfactor Command
- An on-premise EJBCA CA accessed via the Keyfactor CA Management Gateway using a managed instance of Keyfactor Command
- A Microsoft CA accessed via the Keyfactor Universal Orchestrator

**Note**: You must install and configure the Keyfactor Universal Orchestrator on a machine in the same forest where the Microsoft CA resides and configure it with CA Support and approve the orchestrator in the Management Portal before creating the CA record.

**Note:** All CAs need to be added manually if you're using Keyfactor Command on a non-domain-joined server.

CAs that need to be configured manually include:

- Domain-joined enterprise or standalone Microsoft CA in a forest with a one-way trust (either direction) with the forest in which Keyfactor Command is installed
- Domain-joined enterprise or standalone Microsoft CA in a forest that has no trust with the forest in which Keyfactor Command is installed
- EJBCA CA
- Non-domain-joined standalone Microsoft CA
- Keyfactor CA gateway in the forest in which Keyfactor Command is installed
   The CA gateways are used to access cloud certificate providers (e.g. the Entrust CA Gateway)
   or to support Microsoft CAs in remote or cloud environments (e.g. the Cross-Forest Gateway).

**Note:** Keyfactor CA gateways are not supported in any configuration other than in the same forest in which Keyfactor Command is installed.

- On-premise Microsoft CA accessed via the Keyfactor CA Management Gateway using a managed instance of Keyfactor Command
- On-premise EJBCA CA accessed via the Keyfactor CA Management Gateway using a managed instance of Keyfactor Command
- Microsoft CA accessed via the Keyfactor Universal Orchestrator

**Note**: You must install and configure the Keyfactor Universal Orchestrator on a machine in the same forest where the Microsoft CA resides and configure it with CA Support and approve the orchestrator in the Management Portal before creating the CA record.

The majority of CA-related functions within Keyfactor Command are supported by both EJBCA and Microsoft CAs. <u>Table 12: CA Function Matrix</u> includes a list of CA-related functions and the support provided by EJBCA and Microsoft CAs.

**Important**: EJBCA integration with Keyfactor Command requires EJBCA version 7.8.1 or higher.

Table 12: CA Function Matrix

	EJBCA CA	Microsoft CA
Template <sup>1</sup> Import	1	✓
CA Threshold Monitoring (Issuance)	1	<b>✓</b>
CA Threshold Monitoring (Failures)		✓.
CA Health Monitoring	1	✓
Certificate Enrollment (PFX)	1	✓.
Certificate Enrollment (CSR)	1	<b>✓</b>
Certificate Revocation	1	✓.
CRL Publishing Following Certificate Revocation	1	<b>✓</b>
Keyfactor Command Private Key Retention and Key Recovery	1	✓.
CA-Level Key Archiving (* no longer supported as of Keyfactor Command v10)		
CA-Level Key Recovery		✓
Approvals in Workflow Builder	1	<b>✓</b>
CA-Level Approvals with Pending, Issued and Denied Alerts		✓
Supports use of Restrict Allowed Requesters for access control	1	1
Requires use of Restrict Allowed Requesters for access control	1	
Requests to the CA can be done in the context of the user initiating the request		1

<sup>&</sup>lt;sup>1</sup>When EJBCA templates are imported, they are named using a naming scheme of <end entity profile name>\_<certificate profile name> for the template name (short name). New templates do not need to be created for Keyfactor Command.

	EJBCA CA	Microsoft CA
Requests to the CA can be done in the context of a single service account	<b>*</b>	✓
Supports use of Universal Orchestrator to access remote CA		*

Tip: Click the help icon (3) next to the page title to open the embedded web copy of the Keyfactor Command Documentation Suite to this section.

You can also find the help icon at the top of the page next to the Log Out button. From here you can choose to open either the Keyfactor Command Documentation Suite at the home page or the Keyfactor API Endpoint Utility.

## **Certificate Authority Operations**

During installation of Keyfactor Command, CA records are created for any Microsoft CAs found in the local forest in which Keyfactor Command is installed. If you have Microsoft CAs in separate forests in a two-way trust with the forest in which Keyfactor Command is installed, you will need to use the import option to import CA records from those forests. If you have Microsoft CAs in any other configuration or EJBCA CAs, you will need to manually configure CA records for them.

# **Importing Trusted Forest CAs**

Microsoft CA and Keyfactor CA gateway records from the Active Directory forest in which Keyfactor Command is installed and any Active Directory forests in a two-way trust with this forest may be imported using the Import option provided they are registered in Active Directory.

Tip: The following permissions (see Security Roles and Claims in the Keyfactor Command Reference Guide) are required to use this feature:

Agents > Management > Read Certificate Authorities > Read Certificate Authorities > Modify

#### To import CA records:

- 1. In the Management Portal, browse to Locations > Certificate Authorities.
- 2. On the Certificate Authorities grid, click the Import action button to import local or two-way trusted forest CAs and Keyfactor CA gateways.

<sup>&</sup>lt;sup>1</sup>For EJBCA, this is the end entity associated with the client certificate used to authenticate to the EJBCA CA.

3. In the Import Certificate Authorities dialog, select the forest from which you want to import in the dropdown and click **Import**.

Figure 210: Import Certificate Authorities

Your certificate authorities and CA gateways will be retrieved from Active Directory in the selected forest and will populate the CA grid. Import once for each forest containing Microsoft CAs that you want to synchronize or use for enrollment.

Once the records are imported, use the **Edit** option (see <u>Adding or Modifying a CA Record on</u> the next page) to configure synchronization and other optional settings for the CA.

**Tip:** This step does not need to be completed for the forest in which Keyfactor Command is installed because those records are imported during the installation process for domain-joined servers unless you have added a new CA or CA gateway following Keyfactor Command installation.

**Note**: Keyfactor CA gateways are not supported in any configuration other than in the same forest in which Keyfactor Command is installed.

**Note**: The import option only works for Microsoft CAs or Keyfactor CA gateways that have been registered in Active Directory. Non-domain-joined servers will not have any options available in this dropdown.

### **Testing a CA Connection**

CA connections can be tested using the action buttons on the Certificate Authority dialog, **Test Connection** and **Save and Test**.

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Agents > Management > Read Certificate Authorities > Read Certificate Authorities > Modify

Certificate Authorities will be tested before they are saved to the database. If the CA can't be verified, an error message with an explanation of the issue will be displayed and added to the Audit Log and you will be given the option to save the configuration anyway.

- For EJBCA, the test checks that the CA name provided is valid for the given EJBCA instance. It validates the hostname, enabled APIs, and authentication certificate. The version is validated (7.8.1 or greater) and connecting to both the REST v1 and SOAP APIs is also validated.
- For Microsoft, the test checks the forest, logical name, CA host, and explicit credentials by using a certutil ping.
- Remote CAs (managed by an orchestrator) will not have the connection tested before saving the
  CA. The **Test Connection** button will be active, but you will receive a message that the connection cannot be tested if you click it. The **Save and Test** button will skip the test when saving.

#### To test a CA record:

- 1. In the Management Portal, browse to *Locations > Certificate Authorities*.
- 2. On the Certificate Authorities grid, click **Add** to add a new CA, or click **Edit** to modify an existing CA, from either the top or right-click menu.
- 3. Follow the instructions for adding or modifying a CA (see Adding or Modifying a CA Record below). Once you have entered the details you want to test, click **Test Connection** or **Save and Test**.
  - a. Upon a successful test, you will receive a green success notification at the bottom of the page and will be returned to the certificates authority grid.
  - b. Upon a test failure, you will receive a pop-up message and an entry will also be added to the audit log. Click **OK** to save the CA despite the error, or click **CANCEL** to return to the dialog to correct any issues.

Figure 211: Save Certificate Authority

## Adding or Modifying a CA Record

Whether your CA has been imported or added manually, you'll need to update it to configure synchronization and other optional settings. When adding or editing your CAs, the connection can now be tested prior to saving.

Tip: The following permissions (see Security Roles and Claims in the Keyfactor Command Reference Guide) are required to use this feature:

Agents > Management > Read Certificate Authorities > Read Certificate Authorities > Modify

CAs that need to be added manually include:

- · A domain-joined enterprise or standalone Microsoft CA in a forest with a one-way trust (either direction) with the forest in which Keyfactor Command is installed
- · A domain-joined enterprise or standalone Microsoft CA in a forest that has no trust with the forest in which Keyfactor Command is installed
- An EJBCA CA
- A non-domain-joined standalone Microsoft CA
- A Keyfactor CA gateway in the forest in which Keyfactor Command is installed that has not been registered in Active Directory

The CA gateways are used to access cloud certificate providers (e.g. Entrust) or to support Microsoft or EJBCA CAs in remote or cloud environments (e.g. the Cross-Forest Gateway).

Note: Keyfactor CA gateways are not supported in any configuration other than in the same forest in which Keyfactor Command is installed.

- An on-premise Microsoft CA accessed via the Keyfactor CA Management Gateway using a managed instance of Keyfactor Command
- An on-premise EJBCA CA accessed via the Keyfactor CA Management Gateway using a managed instance of Keyfactor Command
- A Microsoft CA accessed via the Keyfactor Universal Orchestrator

Note: You must install and configure the Keyfactor Universal Orchestrator on a machine in the same forest where the Microsoft CA resides and configure it with CA Support and approve the orchestrator in the Management Portal before creating the CA record.

Note: All CAs need to be added manually if you're using Keyfactor Command on a nondomain-joined server.

If your Microsoft CA or Keyfactor CA gateway is domain-joined in the forest in which Keyfactor Command is installed or a forest in a two-way trust with this forest and has been registered in Active Directory, you can opt to add a record for it manually, but it is generally easier to use the import option (see Importing Trusted Forest CAs on page 353).

**Important**: In order for CAs to successfully synchronize to the Keyfactor Command database and perform other functions (e.g. enrollment), the service account under which Keyfactor Command is making the request to the CA must be granted appropriate permission to the CA database as per *Grant the Keyfactor Command Users and Service Account(s) Permissions on the CAs* in the *Keyfactor Command Server Installation Guide*.

To create a CA record manually or edit an existing one:

- 1. In the Management Portall, browse to *Locations > Certificate Authorities*.
- 2. On the Certificate Authorities grid, click **Add** to add a new CA, or click **Edit** from either the top or right-click menu to modify an existing one.
- 3. At the top of the dialog, choose an appropriate CA communication protocol in the **Select CA Communication Protocol** dropdown. The options are:
  - DCOM-Select this option for Microsoft CAs and CA gateways.
  - HTTPS—Select this option for EJBCA CAs and AnyCAGateway REST.

This field cannot be modified on an edit.

4. The remainder of the Certificate Authority dialog shows four tabs. Only the first three are used for EJBCA CAs. Complete the Certificate Authority dialog with the appropriate data using the following instructions:

### The Basic Tab

### **Details**

In the *Details* section populate the **Logical Name**, **Host Name** and **Configuration Tenant** fields with the appropriate information for the CA. (The **Enforce Unique DN** and **Create new End Entity when renewing or reissuing certificates** checkboxes apply only to the HTTPS Certificate Authorities).

The Configuration Tenant field cannot be modified on an edit.

**Tip**: Previous versions of Keyfactor Command referred to the **Configuration Tenant** as the **Template Forest**.

Domain-Joined Enterprise or Standalone Microsoft CA in a Forest with a One-Way Trust (either direction) with the Forest in which Keyfactor Command is Installed

Logical Name—The logical name of the CA in the remote forest. For example: Corp2ls-suingCA1

- **Host Name**—The fully qualified domain name of the server on which the CA in the remote forest is installed. For example: corp2ca01.keyother.com
- Configuration Tenant—The DNS domain name for the Active Directory forest in which the CA resides. For example: keyother.com

Domain-Joined Enterprise or Standalone Microsoft CA in a Forest that has No Trust with the Forest in which Keyfactor Command is Installed

- Logical Name—The logical name of the CA in the remote forest. For example: Corp3IssuingCA1
- Host Name—The fully qualified domain name of the server on which the CA in the remote forest is installed. For example: corp3ca01.keyother2.com
- Configuration Tenant—The DNS domain name for the Active Directory forest in which the CA resides. For example: keyother2.com

#### EJBCA CA

Logical Name—The logical name of the EJBCA CA. For example: CorpCA1

**Note**: EJBCA CA logical names are case sensitive (e.g. CorpCA1 is not the same as CORPCA1).

- Host URL—The URL pointing to the EJBCA CA. For example: https://e-jbca01.keyother3.com. If the URL provided does not have a virtual directory (/ejbca or otherwise) the /ejbca will be provided, otherwise it will use what is supplied in the URL.
- Configuration Tenant—A reference ID for the EJBCA CA server. For EJBCA CAs, this
  does not need to be the DNS domain name. The short hostname of the EJBCA CA
  server makes a good reference ID.

**Important:** EJBCA and Microsoft CAs cannot be configured with the same *Configuration Tenant*, so do not set this to the DNS domain name if you will also be configuring Microsoft CAs in the same DNS domain.

### Enforce Unique DN

Checking this will cause Keyfactor Command, upon enrollment, to search the EJBCA CA for end entities with DNs that match the DN in the certificate request. If a matching DN is found, the process will update the existing end entity in EJBCA with the new certificate request information rather than creating a new end entity. If you enable this option in Keyfactor Command, it must also be enabled on the matching EJBCA CA. A mismatch in these settings can result in enrollment failures.

### **Edit CA**

## CA Name: ManagementCA

Figure 212: Enforce unique DN Setting on the EJBCA CA

The value of the Keyfactor Command **Enforce Unique DN** setting is verified for each certificate request:

- ° If unset, enrollment proceeds as usual.
- If set, EJBCA is searched for an end entity associated with the DN and CA in the certificate request and:
  - o If none is found, the enrollment proceeds as usual.
  - If one or more is found, the end entity in EJBCA is updated with the information from the certificate request, so that the new certificate request is tied to the same end entity as the existing certificate (or the first one found, if multiple are found). A new password is generated and the enrollment proceeds as usual.

## Non-Domain-Joined Standalone Microsoft CA

- Logical Name—The logical name of the standalone CA. For example: CorpSARootCA1
- Host Name—The fully qualified domain name of the server on which the standalone CA is installed. For example: saroot01.keyexample.com

 Configuration Tenant—The DNS domain name for the standalone CA. For example: keyexample.com

Remote CA Accessed via a Keyfactor Universal Orchestrator

- Logical Name—The logical name of the CA in the remote forest to which the orchestrator will be connecting for synchronization. For example: Corp4IssuingCA1
- Host Name—The fully qualified domain name of the CA in the remote forest to which the
  orchestrator will be connecting for synchronization. For example: corp4ca01.keyother4.com
- Configuration Tenant—The DNS domain name for the Active Directory forest in which the orchestrator is operating and in which the CA resides. For example: keyother4.com

**Note:** You must install and configure the Keyfactor Universal Orchestrator on a machine in the same forest where the CA resides, configure it with CA Support and approve the orchestrator in the Management Portal before creating the CA record.

Domain-Joined Enterprise or Standalone Microsoft CA in the Forest in which Keyfactor Command is Installed

- Logical Name—The logical name of the CA in the local forest. For example: CorplssuingCA1
- **Host Name**—The fully qualified domain name of the server on which the CA in the local forest is installed. For example: corpca01.keyexample.com
- Configuration Tenant—The DNS domain name for the Active Directory forest in which the CA resides. For example: keyexample.com

### Keyfactor CA Gateway

- Logical Name—The logical name of the CA gateway in the local forest. For example: EntrustGateway
- Host Name—The fully qualified domain name of the server on which the CA gateway in the local forest is installed. For example: entgtw1.keyexample.com
- Configuration Tenant—The DNS domain name for the Active Directory forest in which the CA resides. For example: keyexample.com

#### Keyfactor CA Management Gateway

• Logical Name—The logical name created when the gateway was configured. The logical name is unique for each CA gateway. For a gateway providing a bridge to an on-premise Microsoft CA, the name configured as the gateway logical name should match the logical name of the Microsoft CA.

- Host Name—The fully qualified domain name of the server in the managed forest environment in which the Keyfactor CA Management Gateway is installed.
- Configuration Tenant—The DNS domain for the Active Directory forest in the managed forest environment in which the Keyfactor CA Management Gateway is installed.

### AnyCAGateway REST

• Logical Name—The logical name, exactly as entered in AnyCA Gateway portal. The logical name is unique for each CA.

**Note:** Logical names are case sensitive (e.g. CorpCA1 is not the same as CORPCA1).

- Host URL—The fully qualified domain name of the server on which the gateway is installed and the port number defined in -ServerPort. For example: CAGateway24.keyexample.com:8443. The Host URL is unique for each CA.
- Configuration Tenant—A reference ID for the gateway CA. Can be any name you choose.
- Create new End Entity when renewing or reissuing certificates
   Checking this will force the gateway CA to create a new end entity for any renew/reissue of a certificate. This is required for the AnyCAGateway REST.

#### Scan

In the *Scan* section, choose when to schedule full and incremental scans. You can choose to run each scan **Weekly**, **Daily** or on an **Interval**:

- If you select **Weekly**, you can select one or more days of the week on which to run the scan and a time when the scan should begin.
- If you select **Daily**, you can set the time of day when the scan should begin.
- If you select **Interval**, you can select a scan frequency of anywhere from every 1 minute to every 12 hours.
- Select Off in the dropdown to disable a scan job.

There are two types of synchronization schedules available for CAs—Full and Incremental. You do not necessarily need to configure both types. A full scan reads all the certificates and certificate requests in the CA database and synchronizes them to Keyfactor Command regardless of their current state in Keyfactor Command. An incremental scan reads the certificates and certificate requests in the CA database that have been generated since the last full or incremental scan and synchronizes them to Keyfactor Command.

A common configuration would be a full scan once or twice a week to provide a clean image of the CA database with a frequent incremental scan to provide timely updates to Keyfactor Command. For a large CA database, a full scan can take a long time to complete. Since an incremental scan only synchronizes updates that have occurred to the CA database since the last synchronization was run, this process is generally quick (other than for the initial synchronization when Keyfactor Command is first installed). The frequency of the incremental scans would depend on the volume of certificate requests coming into the CA.

**Note**: For EJBCA CAs, if the certificate profile has a *Validity Offset* configured to a value greater than the value configured in the *CA Sync Backward Offset Minutes* application setting (15 minutes by default), certificates requested outside of Keyfactor Command will not be picked up on incremental scans. These certificates will only appear in Keyfactor Command on a full synchronization. The *CA Sync Backward Offset Minutes* application setting should be set to the same number of minutes as the *Validity Offset* value, if *Validity Offset* is configured.

Figure 213: EJBCA Certificate Profile Validity Offset Greater than 15 Minutes

**Note:** For EJBCA CAs, if the certificate profile has *Allow Backdated Revocation* configured and a revocation is completed outside of Keyfactor Command with a backdate of greater than 10 minutes, the revocation will not be picked up on incremental scans. These revocations will only appear in Keyfactor Command on a full synchronization.

Figure 214: EJBCA Certificate Profile Backdated Revocation

For Microsoft CAs, if desired check the **Sync External Certificates** box to allow foreign certificates that have been imported into a Microsoft CA to be synchronized to Keyfactor Command along with the certificates issued by the Microsoft CA. This option does not appear for HTTPS CAs.

#### **Enrollment**

In the *Enrollment* section, check the **Enable PFX Enrollment** and/or **Enable CSR Enrollment** box to enable enrollment for the CA through Keyfactor Command.

If you wish to use *One-Click Renewal* for certificates, the **Allow One-Click Renewals** option must be enabled in both the templates and CAs to which you want *One-Click Renewal* to apply (see *Certificate Template Operations* and *Certificate Authority Operations* in the *Keyfactor Command Reference Guide*). For more information about one-click renewals, see *Certificate Operations: Renew* in the *Keyfactor Command Reference Guide*.

**Note**: In order to perform enrollment through Keyfactor Command, the account making the request to the CA must be granted appropriate enroll permissions on the CA itself. Which account this is depends on the authorization configuration (see <a href="Authorization">Authorization</a> Methods Tab on page 368):

- If **Use Explicit Credentials** is set to *true* (box checked), enrollment is done in the context of that explicit user and that user needs permission.
- If **Use Explicit Credentials** is set to *false* (box not checked), the user context in which enrollment is done will vary (see <u>Grant the Keyfactor Command Users and Service Account(s) Permissions on the CAs</u>).

Enrollment is not supported using NTLM authentication.

If desired, check the **Require Subscriber Terms** box to add a checkbox on the enrollment pages to force users to agree to a custom set of terms before enrolling. Configure a link to the custom terms using the *URL* to *Subscriber Terms* application setting (see <u>Application Settings: Enrollment Tab on page 610).</u>

**Tip:** To fully configure enrollment for the CA, you will also need to configure access on the Authorization Methods tab (see <u>Authorization Methods Tab on page 368</u>) and configure templates (see <u>Certificate Template Operations on page 382</u>).

Figure 215: Certificate Authority Basic Tab for a Microsoft CA

Figure 216: Certificate Authority Basic Tab for an AnyGateway REST CA

**Note:** When configuring an HTTPS CA, **Enforce Unique DN** and **Create new End Entity when renewing or reissuing certificates** are mutually exclusive options; they CANNOT both be selected since they're telling the CA to do opposite things.

- Enforce Unique DN will be DISABLED if Create new End Entity when renewing or reissuing certificates is ENABLED.
- Create new End Entity when renewing or reissuing certificates will be DISABLED if Enforce Unique DN is ENABLED.
- Create new End Entity when renewing or reissuing certificates is set to false by default.

### **Advanced Tab**

#### **Details**

In the *Details* section, if you've opted to use the Keyfactor Universal Orchestrator to communicate with a remote CA, check the **Use Orchestrator** box and choose the appropriate orchestrator from the dropdown.

Note: The Orchestrator dropdown is only active if the **Use Orchestrator** box is checked. If **Use Orchestrator** is checked, the Orchestrator dropdown will populate with any orchestrators approved in Keyfactor Command with the CA capability. The Keyfactor Universal Orchestrator must be installed on a machine in the forest where the remote CA resides, installed and configured as per *Universal Orchestrator*[ in the *Keyfactor Orchestrators Installation and Configuration Guide*. In addition, in the Management Portal, the Keyfactor Universal Orchestrator must be configured as per <u>Orchestrator Management on page 497</u>.

## Monitoring

In the *Monitoring* section, check the **Enable Monitoring** box to turn on email alerting when certificate issuance or failures (including denials) since the last threshold alert was sent falls outside the configured limits. You can choose to schedule the alerts either for daily delivery at a specified time or at intervals of anywhere from every 1 minute to every 12 hours. Daily is the most common configuration. Set the thresholds for:

• **Issuance Greater Than**—You will receive an alert if more certificates are issued by this CA in the time period between executions of the alert than the number you set here. The value set here must be greater than, or equal to, the value set for *Issuance Less Than*.

- Issuance Less Than—You will receive an alert if fewer certificates are issued by this CA in the time period between executions of the alert than the number you set here. The minimum allowed value for Issuance Less Than is 1.
- Failures Greater Than—You will receive an alert if more certificate requests fail or are denied by this CA in the time period between executions of the alert than the number you set here. Zero is a valid setting (meaning you will receive an alert for a single failure).

**Note:** EJBCA CAs do not return failure counts using the API, so failures cannot be reported with threshold monitoring for EJBCA CAs.

In addition to configuring the thresholds for each CA, you must also configure the email recipients on the Alert Recipients tab (see <u>Certificate Authority Monitoring on page 379</u>) of the Certificate Authorities page. Monitoring is not supported for CAs accessed with the Keyfactor Universal Orchestrator.

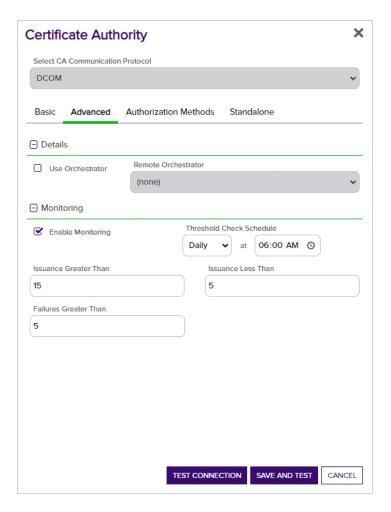

Figure 217: Certificate Authority Advanced Tab for Microsoft CA

# **Authorization Methods Tab**

On the Authorization Methods tab, you configure how access for management tasks and enrollment occurs for the CA.

**Tip**: Keyfactor recommends the following configuration for most DCOM CAs to support access control within Keyfactor Command:

- Use Explicit Credentials: True or false as required by the environment
- Delegate Management Operations: False (box unchecked)
- Delegate Enrollment: False (box unchecked)
- Restrict Allowed Requesters: Set to the Keyfactor security roles allowed to perform certificate enrollment for this CA. If you're using workflow (see Workflow

<u>Definitions on page 230</u>), the users who hold these roles are the ones who are able to initiate workflows. This is entirely separate from the roles configured within workflows, which control the users who are able to approve workflows.

Note: If Use Explicit Credentials, Delegate Management Operations and Delegate Enrollment are all set to false (box unchecked), requests to the CA are made in the context of the Keyfactor API application pool user. For more information, see Grant the Keyfactor Command Users and Service Account(s) Permissions on the CAs in the Keyfactor Command Server Installation Guide.

Use Explicit Credentials (DCOM-Microsoft CAs)

The **Use Explicit Credentials** option allows you to configure specific credentials that will be used to make requests to the CA for management tasks and enrollment. This is generally used for Microsoft CAs where Windows integrated authentication is not supported. Integrated authentication is generally supported for Microsoft CAs, Keyfactor CA gateways, or Keyfactor CA management gateways on servers joined to the local Active Directory forest in which Keyfactor Command is installed and any Active Directory forests in a two-way trust with this forest.

To configure this option, check the **Use Explicit Credentials** box and enter a username in the format DOMAIN\username for a service account user in the forest in which the CA resides or, for non-domain-joined machines, a local machine account on the machine on which the CA is installed. Click the **Set Explicit Password** button and in the Set Explicit Password dialog, choose from No Value, Load from Keyfactor Secrets or Load From PAM Provider.

A Keyfactor secret is a user-defined password or other information that is encrypted and stored securely in the Keyfactor Command database. Although Keyfactor recommends using Privileged Access Management (see <a href="Privileged Access Management (PAM)">Privileged Access Management (PAM)</a> on page 744) as a more secure solution to secure information, Keyfactor Secret is an option for customers that do not already have a relationship with a PAM provider such as CyberArk or Delinea.

**Important:** Keyfactor highly recommends that you use strong passwords for any accounts or certificates related to Keyfactor Command and associated products, especially when these have elevated or administrative access. A strong password has at least 12 characters (more is better) and multiple character classes (lowercase letters, uppercase letters, numeral, and symbols). Ideally, each password would be randomly generated. Avoid password re-use.

Select the **Load From Keyfactor Secrets** radio button as the *Secret Source* if you want Keyfactor Command to encrypt and store the password in the Keyfactor Command database. Enter and confirm a password.

Select the **Load from PAM Provider** radio button as the *Secret Source* if you want to store the password in a supported third-party PAM solution (see <u>Privileged Access Management (PAM) on page 744</u>). The remaining fields on the dialog will vary depending on the PAM provider. For example:

## **CyberArk**

Select your CyberArk provider in the **Providers** dropdown if your PAM provider is CyberArk (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining fields in the dialog will then be:

- Safe—The name of the safe the credential resides in.
- Object—The name of the username or password object in the safe.
- Folder—The path and name of the folder that stores the object (e.g. Root or Root\MyDir).

## Delinea

Select your Delinea provider in the **Providers** dropdown if your PAM provider is Delinea (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining field in the dialog will then be:

- Secret Server Secret ID—The numeric ID of the secret to retrieve from Secret Server.
- Secret Field Name—The name of the field to use when retrieving a secret form Secret Server.

## Hashicorp

Select your Hashicorp Vault provider in the **Providers** dropdown if your PAM provider is Hashicorp Vault (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining field in the dialog will then be:

- KV Secret Key—The key of the secret to retrieve from the Hashicorp Vault.
- KV Secret Name—The name of the secret to retrieve from the Hashicorp Vault.

This service account user needs appropriate permissions in the CA security settings to accomplish the tasks you plan to carry out for this CA through the Management Portal. For example:

- Certificate enrollment
- Certificate revocation
- Certificate key recovery
- · Certificate request approval and denial

These tasks will be carried out on the CA in the context of the credentials you provide here. Access control for these tasks is controlled with Keyfactor Command security (see Security Roles and Claims on page 623) and the Restrict Allowed Requesters option, below.

Note: When this option is configured, enrollment and other tasks (e.g. revocation) are done in the context of the user configured here, not the user making the request in Keyfactor Command. This overrides the existing AD security policy used by Keyfactor Command.

Note: Once you have established explicit credentials to a forest for a CA, the forest will be included in the forest dropdown on the Import Templates dialog (see Certificate Templates on page 380).

Tip: The Use Explicit Credentials option is not needed if you are accessing your CA using a Keyfactor Universal Orchestrator. Enrollment is not supported when accessing a CA using an orchestrator, so the Restrict Allowed Requesters option is not relevant for this type of CA configuration.

The **Use Explicit Credentials** option is not used for EJBCA CAs.

Delegate Management Operations & Delegated Enrollment (DCOM-Microsoft CAs & CA Gateways)

Important: The Delegate options are only supported when using Active Directory as an identity provider.

The Delegate Management Operations and Delegate Enrollment boxes are used for CAs that support Windows integrated authentication to allow interactions with the CAs via Keyfactor Command to be done in the context of the user authenticated to Keyfactor Command using Kerberos authentication. These options also apply to users who authenticate to Keyfactor Command using Basic authentication, since Keyfactor Command performs pseudo delegation for these users. These options are not supported for users who authenticate using NTLM or Token authentication.

Integrated authentication is generally supported for Microsoft CAs, Keyfactor CA gateways, or Keyfactor CA management gateways on servers joined to the local Active Directory forest in which Keyfactor Command is installed and any Active Directory forests in a two-way trust with this forest. If delegation is enabled, when a user authenticates with Kerberos or Basic authentication to Keyfactor Command, the Keyfactor Command server can delegate the user's credentials to the CA to provide end-to-end authentication without unpacking the credentials at the Keyfactor Command layer.

If you choose to disable one or both of the delegation options and have not enabled the *Use Explicit Credentials* option, interaction with the CA for the type of activity that is not delegated (e.g. management operations) is done in the context of the service account under which the Keyfactor API application pool is running. For more information, see *Grant the Keyfactor Command Users and Service Account(s) Permissions on the CAs* in the *Keyfactor Command Server Installation Guide*.

**Note**: Use of explicit credentials is mutually exclusive of delegation.

**Important:** If you configure CA delegation and are using Kerberos authentication, you must also configure Kerberos constrained delegation for the CAs as per *Configure Kerberos Constrained Delegation (Optional)* in the *Keyfactor Command Server Installation Guide*.

The types of interactions affected by these settings include:

- Approval of pending certificate requests (Delegate Management Operations)
- Denial of pending certificate requests (Delegate Management Operations)
- Revocation of certificates (Delegate Management Operations)
- Certificate key recovery (Delegate Management Operations)
- Certificate enrollment (Delegate Enrollment)

Note: If a workflow (see Workflow Definitions on page 230) is configured with a step that will result in a suspended state (e.g. pausing to wait for approvals) and the CA for the request is configured for delegation, the enrollment or revocation request made via the workflow will fail with an error indicating that the failure occurred because CA delegation is enabled. Workflows are not supported with CA delegation in the case where a suspended state may occur because it's possible that the initiating user's context may not be available all the way to the conclusion of the workflow. When using workflow with steps that will result in a suspended state, do not use CA delegation. Instead, use the Keyfactor Command access control model provided by the Restrict Allowed Requesters option for enrollment (see Restrict Allowed Requesters

(DCOM-Microsoft and HTTPS-EJBCA CAs) on the next page) and the Revoke permission for certificates at both the global and collection levels (see Certificate Collection Permissions on page 628).

If you choose to enable delegation, be aware that each user performing one of these delegable operations through the Management Portal must have the appropriate permissions to accomplish this task configured in the CA security settings.

Important: Granting users permissions in the CA security settings for certificate revocation, certificate key recovery, or certificate request approval and denial-e.g. the Issue and Manage Certificates permission—in order to support delegation of these operations through the Management Portal also grants these permissions to the users when operating outside the Keyfactor Command Management Portal. Any risk associated with this can be mitigated by implementing the Keyfactor Whitelist Policy Handler on each CA where such permissions are granted (see Installing the Keyfactor CA Policy Module Handlers in the Keyfactor Command Server Installation Guide).

The Delegate Management Operations and Delegate Enrollment options are not used for EJBCA CAs.

Restrict Allowed Requesters (DCOM-Microsoft and HTTPS-EJBCA CAs)

The Restrict Allowed Requesters option is used to select Keyfactor Command security roles that a user must belong to in order to successfully enroll for certificates in Keyfactor Command via this CA. This option must be used to provide enrollment access if the Delegate Enrollment option is disabled. With this option checked, you must include at least one role in the Allowed Requester Security Roles table for enrollment to work.

This option is supported for all CAs, but it must be used for:

Implementations using Keyfactor Identity Provider as an identity provider.

for the selected security roles at the CA level on a Microsoft CA.

- Microsoft CAs where Windows integrated authentication is not supported. Integrated authentication is generally supported for Microsoft CAs, Keyfactor CA gateways, or Keyfactor CA management gateways on servers joined to the local Active Directory forest in which Keyfactor Command is installed and any Active Directory forests in a two-way trust with this forest. Since Keyfactor Command cannot make use of the access control model of the CA itself to determine which users can enroll for certificates at either a template or CA level without using integrated authentication, this setting replaces that functionality. This setting is similar to setting request certificates
- · EJBCA CAs.

The Restrict Allowed Requesters check box must be checked—and the Allowed Requester Security Roles populated—if the Use Explicit Credentials box is checked for a Microsoft CA that isn't accessed using integrated authentication.

**Tip:** For Microsoft CAs in a two-way trust environment you don't necessarily need to enable **Restrict Allowed Requesters** on the CA, though this may be required in some circumstances depending on the security configuration in the environment. However, templates for a two-way trust environment always require configuration of this option at a template level to support enrollment (see <a href="Certificate Template Operations on page 382">Certificate Template Operations on page 382</a>).

In addition to granting permissions at the CA level using this option, you need enable the **Restrict Allowed Requesters** option to grant permissions on a template-by-template basis (see Certificate Templates on page 380).

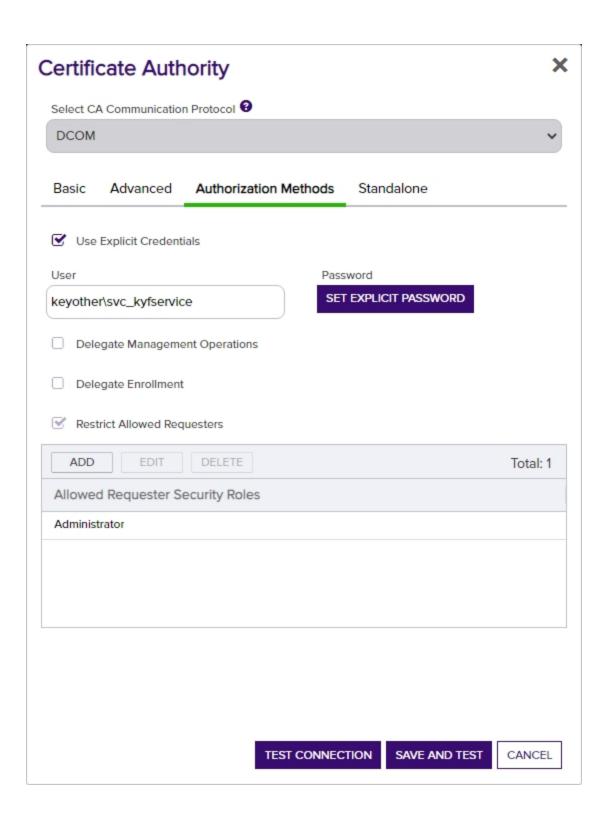

**Note**: Access control for other types of interactions with the CA (e.g. revocation) is managed with standard security roles (e.g. the certificate revoke permission) at both the global and certificate collection level.

Authentication Certificate (HTTPS-EJBCA CAs)

Click the **Select Authentication Certificate** button to upload a client certificate in PKCS#12 format used to provide authentication to the EJBCA CA. This certificate is used to authenticate to the EJBCA database for synchronization, enrollment and management of certificates.

**Note**: Once you have established a connection to the EJBCA CA, it will be included in the forest dropdown on the *Import Templates* dialog (see <u>Certificate Templates on page 380</u>).

Figure 218: Certificate Authority Authentication Methods Tab for a DCOM-Microsoft CA

Figure 219: Certificate Authority Authentication Methods Tab for an HTTPS-EJBCA CA

## Standalone Tab (Microsoft CAs)

To configure a standalone Microsoft CA, check the **Standalone** box.

Check the **Enforce RFC 2818 Compliance** box to require that certificate enrollments made through the Keyfactor Command Management Portal for this CA include at least one DNS SAN. This causes the CN entered in PFX enrollment to automatically be replicated as a SAN, which the user can either change or accept. For CSR enrollment, if the CSR does not have a SAN that matches the CN, one will automatically be added to the certificate if this is set.

If you have configured the CA for PFX enrollment on the Basic tab, the *Key Retention* field drop-down will display. Select a retention type. Enter the number of days, weeks, months, or years to keep the encrypted private key stored in the Keyfactor Command database based on the type

selected, then select the desired time frame (Day(s), Week(s), Month(s), or Year(s)). You will not have the option to choose a retention timeframe if you choose Indefinite.

Configuring private key retention allows the private keys for certificates enrolled through Keyfactor Command to be stored, encrypted, in the Keyfactor Command database for a userdefinable period of time.

The private key retention configuration options are:

Blank

The private key will not be retained if the box is unchecked, or the blank option is selected.

Indefinite

The private key will be retained until it is explicitly deleted.

After Expiration

The private key will be retained until the specified number of days, weeks, months or years after the certificate expires, at which point it will be scheduled for deletion.

The private key will be retained until the specified number of days, weeks, months or years after the date on which the certificate was issued, at which point it will be scheduled for deletion.

Note: When the retention period is stored in the database, weeks are converted to 7 days, months are converted to 30 days, and years are converted to 365 days.

Tip: Setting the retention period to 0 will cause the private keys to be purged by the private key clean up job when it next runs, after the certificate expires or after the certificate is issued.

Figure 220: Certificate Authority Standalone Tab

5. Click **Test and Save** to add or update the CA, or click **Test Connection** to test the CA prior to saving (see <u>Testing a CA Connection on page 354</u>) for more information, including options for a failed CA test.

**Tip:** Once a CA record has been created for your CA, go to certificate templates (see <u>Certificate Templates on page 380</u>) and import templates for the CA. Template import is supported for both Microsoft and EJBCA CAs. Template import is not supported for the following:

- Non-domain-joined standalone Microsoft CAs (these don't use templates)
- CAs accessed via the Keyfactor Universal Orchestrator

## **Deleting a CA Record**

Tip: The following permissions (see Security Roles and Claims in the Keyfactor Command Reference Guide) are required to use this feature:

Agents > Management > Read Certificate Authorities > Read Certificate Authorities > Modify

#### To delete a CA record:

- 1. In the Management Portal, browse to Locations > Certificate Authorities.
- 2. On the Certificate Authorities grid, highlight the row in the CA grid and click Delete at the top of the grid or right-click the CA and choose **Delete** from the right-click menu.
- 3. On the Confirm Operation alert, click **OK** to confirm or **Cancel** to cancel the operation.

### A CA cannot be deleted if:

- · It has scanning tasks enabled.
- It has certificates associated with it in the Keyfactor Command database.
- It is the last CA for its Configuration Tenant and there are certificate templates (see Certificate Templates on the next page) for that Configuration Tenant in Keyfactor Command.

## **Certificate Authority Monitoring**

The two types of monitoring which Keyfactor Command offers for certificate authorities are configured on the Alert Recipients tab of the Certificate Authorities page at Locations > Certificate Authorities. Monitoring is not supported for CAs accessed with the Keyfactor Universal Orchestrator.

## **Certificate Authority Health Monitoring**

Enable certificate authority health monitoring to receive email alerts when one or more of your CAs is not responding. Only CAs configured for synchronization will be monitored for health. To enable health monitoring, configure one or more recipients to receive the email messages and configure a health check schedule. You can choose to schedule the health checks either for daily at a specified time or at intervals of anywhere from every one minute to every 12 hours.

## **Certificate Authority Threshold Alerts**

Enable threshold alerting to receive email alerts when a CA issues more or fewer certificates or experiences more failures or denials than configured for monitoring on the CA. Setting threshold monitoring is a two-step process:

- 1. Configure monitoring on the advanced tab (see Advanced Tab on page 366) for each CA.
- 2. Set the email recipients for the alerts on the alert recipients tab of the certificate authorities page.

## Certificate Authorities 9

Certificate Authorities define the Microsoft-based certificate storage. Use the 'Import' button to automatically obtain Microsoft Certificate Authorities from your Active Directory. Certificate Authorities can also be defined manually. At least one Certificate Authority must be defined prior to creating a synchronization stedule. Data for the CA sections of the dashboard is generated from certificates retrieved during CA synchronization tasks. Any CAs that have not been configured for synchronization will not appear as available for addition on the dashboard.

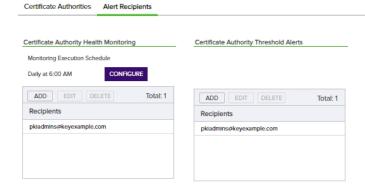

Figure 221: Certificate Authority Monitoring Recipients

## 2.1.8.2 Certificate Templates

During initial provisioning, the certificate templates in the primary Active Directory forest (the forest in which Keyfactor Command is installed) will be imported automatically by the Keyfactor Command configuration wizard. Templates for additional forests can be imported in a number of ways:

- For Microsoft CAs domain-joined to forests in a two-way trust with the primary forest, you can use the *Import Templates* option at any time.
- For Microsoft CAs domain-joined to forests in a one-way trust with the primary forest or to a
  forest having no trust with the primary forest, you can use the *Import Templates* option after you
  have configured a CA record for at least one Microsoft CA in the non-primary forest and enabled
  the *Use Explicit Credentials* option with credentials for the non-primary forest.
- For EJBCA CAs, you can use the Import Templates option after you have configured a CA record for at least one EJBCA CA.
- Templates that are associated with certificates that have been requested from a Microsoft CA in
  a forest other than the primary forest will appear in the templates grid as those certificates are
  synchronized to Keyfactor Command if you configure CA synchronization for the CA even if you
  don't use the import option.
- There's an automated process to import templates once every hour, on the hour. Templates are imported for Microsoft CAs in the primary forest, Microsoft CAs in any forests in a two-way trust with the primary forest, and any CAs that can be reached using the credentials configured in the CA record (the *Use Explicit Credentials* option for Microsoft CAs or the client certificate for EJBCA CAs). The automated template import only runs for CAs for which there is an active CA synchronization job configured. This automated sync is only enabled if the *Sync Templates* option on the **Service tab** of the Configuration Wizard is selected during installation (see *Install the Main Keyfactor Command Components on the Keyfactor Command Server(s): Service Tab* in the *Keyfactor Command Server Installation Guide*).

You will need to import templates if you add a new template or change the name or key size of a template after it has been imported into Keyfactor Command and don't want to wait for the automated import process or have not configured the automated process (see <a href="Importing Certificate">Importing Certificate</a> Templates on the next page).

**Note**: When a template is imported into Keyfactor Command, a default template policy is added. Similarly, if a template is updated and no policy exists, a default policy is saved for it. The default policies have null values for everything, and will not override the system-wide policies.

Certificate templates need to be configured to support PFX and CSR enrollment (see Configuring Template Options on page 388).

Note: When EJBCA templates are imported, they are named using a naming scheme of:

- Short Name: <end entity profile name>\_<certificate profile name>
- Display Name: <end entity profile name> (<certificate profile name>)

Only certificate profiles configured as *available* in a given end entity profile will be imported as templates associated with the given end entity profile name.

#### Certificate Templates 9 Certificate Authorities define what certificate templates are known to the system. Templates are automatically imported during the running of the configuration wizard. Use the 'Import' button to obtain Template definitions created after the running of the configuration wizard from your Configuration Tenants. Figure 222: Certificate Templates

**Tip**: Click the help icon (2) next to the page title to open the embedded web copy of the *Keyfactor Command Documentation Suite* to this section.

You can also find the help icon at the top of the page next to the **Log Out** button. From here you can choose to open either the *Keyfactor Command Documentation Suite* at the home page or the *Keyfactor API Endpoint Utility*.

## **Certificate Template Operations**

Certificate templates are imported from their source rather than created in Keyfactor Command, which means there are limited operations that need to be performed in Keyfactor Command in relation to them. Supported actions on the certificate template page include:

### • Import Templates

The certificate templates in the primary Active Directory forest (the forest in which Keyfactor Command is installed) will be imported automatically by the Keyfactor Command configuration wizard during the Keyfactor Command installation if Keyfactor Command is installed on a domain-joined server. The template import option is used for templates from other sources, new templates created or edited after the Keyfactor Command installation, or template import for non-domain-joined Keyfactor Command servers.

## Configure System-Wide Settings

The global settings option allows you to configure regular expressions, certificate subject defaults and policies that apply to all enrollments unless overridden by template-level settings.

## • Edit Template Options

Although templates are imported from their source, there are multiple Keyfactor Commandspecific settings that can be configured on the templates to allow them to be used within the product.

### View Certificates for a Template

The view certificates option takes you to the certificate search interface with the query field populated by the selected template.

## **Importing Certificate Templates**

You only need to import templates if you have EJBCA CAs, Microsoft CAs in forests other than the forest in which Keyfactor Command was installed, are running Keyfactor Command on a non-domain-joined server, or have added a new template or changed the name or key size of a template after it has been imported into Keyfactor Command and don't want to wait for the automated import process or have not configured the automated process (see Certificate Templates on page 380).

To import certificate templates:

- 1. In the Management Portal, browse to Locations > Certificate Templates.
- 2. On the Certificate Templates page, click Import Templates.
- 3. In the Select Configuration Tenant dialog, select a configuration tenant in the dropdown.

**Tip:** Previous versions of Keyfactor Command referred to the **Configuration Tenant** as the **Template Forest**.

If you have a forest in a two-way trusted relationship with the forest in which Keyfactor Command is installed or have configured a Microsoft CA with the *Use Explicit Credentials* option or an EJBCA CA, the configuration tenant for this CA will appear in the dropdown. Import once

for each configuration tenant containing templates that you want to import. The import process may take several seconds.

Note: When EJBCA templates are imported, they are named using a naming scheme of:

- Short Name: <end entity profile name> <certificate profile name>
- Display Name: <end entity profile name> (<certificate profile name>)

Only certificate profiles configured as available in a given end entity profile will be imported as templates associated with the given end entity profile name.

Tip: Out of the box, only templates for Microsoft CAs in the forest to which the Keyfactor Command server is joined and any Microsoft CAs in forests in a two-way trust with this forest can be imported using the template import. In order to import templates for other Microsoft CAs, you need to configure the Use Explicit Credentials option for each Microsoft CA for which you want to import templates and enter credentials valid for that CA with appropriate permissions to allow Keyfactor Command to query the CA for template records (see Authorization Methods Tab on page 368). Only one CA in each forest needs to be configured to allow the template import to function.

# **Configuring System-Wide Settings**

System-wide settings apply to all enrollments done through Keyfactor Command unless they are overridden by template-specific settings (see Enrollment Regexes Tab on page 397, Enrollment Defaults Tab on page 399, and Policies Tab on page 400). Although system-wide settings are configured on the templates page, they also apply to enrollments done without a template (e.g. standalone CAs).

Note: System-wide settings replaced and enhanced selected application settings for enrollment beginning in release 10.

To configure system-wide options:

- 1. In the Keyfactor Command Management Portal, browse to Locations > Certificate Templates.
- 2. On the Certificate Templates page, click System-Wide Settings at the top of the grid.
- 3. When you open the system-wide settings, you will see three tabs. Configure the system-wide setting information with the appropriate data using the following instructions.
- 4. Click Save to save the system-wide settings. Click Back to return to the certificate templates page.

#### **Enrollment RegExes Tab**

Regular expressions for enrollment are used to validate that the data entered in the certificate subject fields meets certain criteria.

Tip: To use a system-wide enrollment regular expression and allow a specific template to bypass that regular expression, you can configure a template-level regular expression for the desired subject part and set it to nothing.

To configure a system-wide regular expression:

- 1. On the Enrollment RegExes tab, double-click a subject part row in the grid, right-click the row and choose Edit from the right-click menu, or highlight the row in the grid and click Edit at the top of the grid.
- 2. On the Enrollment RegEx dialog, in the RegEx field, enter a regular expression against which to validate the subject part. See Regular Expressions on page 403 for examples.
- 3. In the Error field, enter an error message to be displayed to the user in the enrollment pages of the Keyfactor Command Management Portal or as a response to an enrollment API request when the subject part referenced in the CSR or entered for a PFX does not match the regular expression defined for the subject part field. Note that the error message already includes the subject part followed by a colon (e.g. Organization: or Invalid O provided: depending on the interface). Your custom message follows this.
- 4. Click **Save** to save the regular expression.

Figure 223: Configure System-Wide Enrollment Regular Expressions

**Tip:** To prevent users from adding a given SAN field to a certificate, create a regular expression on the field with the following value:

^\$

This will disallow entry of any data in the SAN field and thus prevent users from submitting the certificate request with this SAN.

#### **Enrollment Defaults Tab**

Enrollment defaults allow you to define default values for select certificate subject parts that will auto-populate on the PFX enrollment and CSR generation pages in the Keyfactor Command Management Portal.

To configure a system-wide enrollment default:

- 1. On the Enrollment Defaults tab, double-click a subject part row in the enrollment defaults grid, right-click the row and choose **Edit** from the right-click menu, or highlight the row in the grid and click **Edit** at the top of the grid.
- On the Enrollment Default dialog, in the Value field, enter a value to auto-populate in the PFX
  enrollment and CSR generation pages of the Keyfactor Command Management Portal. During
  PFX enrollment or CSR generation, the user can accept the value or modify it; it is not
  enforced.
- 3. Click Save to save the default.

**Note:** System-wide enrollment defaults do not apply to requests made with CSR enrollment or the Keyfactor API.

Figure 224: Configure System-Wide Enrollment Defaults

**Tip:** See also the *Subject Format* application setting, which takes precedence over enrollment defaults at both the system-wide and template level (see <u>Application Settings: Enrollment Tab on page 610</u> in the *Keyfactor Command Reference Guide*).

### Policies Tab

**Note**: When a template is imported into Keyfactor Command, a default template policy is added. Similarly, if a template is updated and no policy exists, a default policy is saved for it. The default policies have null values for everything, and will not override the system-wide policies.

Policies for templates cover the following settings:

#### **Enrollment Policies**

Allow Wildcards

Enable this option to allow certificates to be created containing wildcards (e.g.

- \*.keyexample.com). The default is enabled.
- · Allow Public Key Reuse

Enable this option to allow public keys to be reused on certificate renewals. The default is enabled.

# • Enforce RFC 2818 Compliance

Enable this option to force certificate enrollments made through Keyfactor Command to include at least one DNS SAN. In the Keyfactor Command Management Portal, this causes the CN entered in PFX enrollment to automatically be replicated as a DNS Name SAN, which will be set to *Read Only*. For CSR enrollment, if the CSR does not have a SAN that matches the CN, one will automatically be added to the certificate if this is set. The default is disabled.

**Tip:** For CA gateways, some cloud providers will automatically include SANs without you needing to enable the **Enforce RFC 2818 Compliance** option. Some cloud providers won't support submission of a SAN that matches the CN (which is the default when you enable the RFC 2818 option). Keyfactor recommends disabling this option for CA gateways.

#### **Supported Key Types**

#### · RSA Key Sizes

A list of RSA key sizes that are valid for enrollment through Keyfactor Command. If a key size is not in this list, enrollment will not be supported for requests specifying that key size. To change the selected values, in the dropdown uncheck any values you do not wish to support. The default values are:

2048, 3072, 4096

## ECC Curves

A list of elliptic curve algorithms that are valid for enrollment through Keyfactor Command. To change the selected values, in the dropdown uncheck any values you do not wish to support. The default values are:

P-256/prime256v1/secp256r1, P-384/secp384r1, P-521/secp521r1

#### Allow Ed448 / Allow Ed25519

Set global template values for allowing Ed448 and Ed25519 keys. Templates that utilize Ed448 or Ed25519 key types can be imported into Keyfactor Command. These key types are only available with EJBCA CAs. Default is disabled.

#### **Editing System-Wide Settings**

Figure 225: Configure System-Wide Policies

# **Configuring Template Options**

The options configured in templates relate to how they appear and function for PFX and CSR enrollment in the Management Portal.

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Certificates > Collections > Metadata Modify

Certificate Templates > Read

Certificate Templates > Modify

To configure template options:

- 1. In the Keyfactor Command Management Portal, browse to Locations > Certificate Templates.
- 2. On the Certificate Templates page, double-click the template, right-click the template and choose **Edit** from the right-click menu, or highlight the row in the template grid and click **Edit** at the top of the grid.
- 3. When you open the certificate template for editing, you will see several tabs. Complete the template information with the appropriate data using the following instructions.
- 4. Click **Save** to save the changes to the template record. Click **Back** to return to the main certificate templates page without saving changes.

**Details Tab** 

## Details

The information in the *Details* section is for reference and cannot be edited. This includes:

- **Template Short Name**—The common name of the template. This name typically does not contain spaces.
- Template Display Name—The display name of the template.
- **Key Size**—The minimum supported key size of the template.
- OID—For a Microsoft certificate template, the object ID of the template retrieved from Active Directory. For an EJBCA certificate template, this field is generated within Keyfactor Command as an object identifier, but does not follow official OID conventions.
- Curve—For ECC templates, the elliptic curve algorithm defined for the certificate template.

#### **Key Types and Sizes**

The Key Types and Sizes section displays all the configured key types information for the template.

#### Friendly Name

In the *Friendly Name* section, enter a **Friendly Name**, if desired. Template friendly names, if configured, appear in template selection dropdowns in place of the template short names. This can be useful in environments where the template short names are long or not very human readable. This setting is not required to enable enrollment or configure private key retention.

#### **Allowed Enrollment Types**

In the *Allowed Enrollment Types* section, click the toggle buttons to enable the options for **CSR Enrollment**, **PFX Enrollment** and/or **CSR Generation** as desired. Enabling these options causes the template to appear in dropdowns in the corresponding section of the Management Portal. In the case of CSR Enrollment and PFX Enrollment, the templates only appear in dropdowns on the enrollment pages if they are available for enrollment from a CA also configured for enrollment within Keyfactor Command (see Adding or Modifying a CA Record on page 355).

If you wish to use *One-Click Renewal* for certificates, the **Allow One-Click Renewals** option must be enabled in both the templates and CAs to which you want *One-Click Renewal* to apply (see *Certificate Template Operations* and *Certificate Authority Operations* in the *Keyfactor Command Reference Guide*). For more information about one-click renewals, see *Certificate Operations: Renew* in the *Keyfactor Command Reference Guide*.

### **Private Key Retention**

In the *Private Key Retention* section, click the toggle button to enable **Private Key Retention**, if desired, and select the retention type in the dropdown. Enter the number of days, weeks, months,

or years to keep the encrypted private key stored in the Keyfactor Command database based on the type selected, then select the desired time frame (Day(s), Week(s), Month(s), or Year(s)). You will not have the option to choose a retention timeframe if you choose **Indefinite**.

Configuring private key retention allows the private keys for certificates enrolled through Keyfactor Command to be stored, encrypted, in the Keyfactor Command database for a user-definable period of time.

Important: Any templates that are configured on the Microsoft CA Issuance Requirements tab for CA certificate manager approval cannot be used for PFX enrollment and associated pending, issued, and denied alerting in Keyfactor Command without configuring private key retention. Edit the template in Keyfactor Command, and on the Details tab check the Private Key Retention box. Set the dropdown to some value other than blank and for retention options of After Expiration or From Issuance, enter a value for the number of days, weeks, months or years to retain the private key. Without this setting, the template will not display on the template dropdown during PFX enrollment.

Figure 226: Microsoft Issuance Requirements on a Template for Manager Approval

**Note:** This does not apply to certificate requests requiring approval at a Keyfactor Command workflow level.

The private key retention configuration options are:

Blank

The private key will not be retained if the box is unchecked, or the *blank* option is selected.

Indefinite

The private key will be retained until it is explicitly deleted.

· After Expiration

The private key will be retained until the specified number of days, weeks, months or years after the certificate expires, at which point it will be scheduled for deletion.

From Issuance

The private key will be retained until the specified number of days, weeks, months or years after the date on which the certificate was issued, at which point it will be scheduled for deletion.

**Note:** When the retention period is stored in the database, weeks are converted to 7 days, months are converted to 30 days, and years are converted to 365 days.

**Tip:** Setting the retention period to 0 will cause the private keys to be purged by the private key clean up job when it next runs, after the certificate expires or after the certificate is issued.

# Certificate Templates 9

Certificate Authorities define what certificate templates are known to the system. Templates are automatically imported during the running of the configuration wizard. Use the 'import' button to obtain Template definitions created after the running of the configuration wizard from your Configuration Tenants.

Editing Template: Enterprise Web Server

Figure 227: Certificate Template: Details Tab for a Microsoft Template

#### **Enrollment Fields Tab**

On the Enrollment Fields tab, you can add custom enrollment fields. These are configured on a pertemplate basis to allow you to submit custom fields with CSR enrollments and PFX enrollments to supply custom request attributes to the CA during the enrollment process. This functionality offers such benefits as:

 Preventing users from requesting invalid certificates, based on your specific certificate requirements per template. · Providing additional information to the CA with the request.

Figure 228: Configure Template: Enrollment Fields Tab

Once created on the template, these values are shown in Keyfactor Command on the PFX and CSR enrollment pages in the *Additional Enrollment Fields* section. The fields are mandatory during enrollment. The data will appear on the CA / Issued Certificates attribute tab for certificates enrolled with a template configured with Keyfactor Command enrollment fields.

**Note**: These are not metadata fields, so they are not stored in the Keyfactor Command database, but simply passed through to the CA. The CA in turn could, via a gateway or policy module, use this data to perform required actions.

On the Enrollment Fields tab you can add, edit and delete enrollment fields.

To add a new enrollment field:

- 1. On the **Enrollment Fields** tab of the selected template click **Add**. If there are existing fields configured they will appear in a list on this tab.
- 2. Enter a Field Name for the new custom field. This name will appear on the enrollment pages.

- 3. Select a Parameter Type. The options are:
  - String: A free-form data entry field.
  - Multiple Choice: Provides a list of acceptable values for the field. A text box will open up below this choice for you to enter the list of acceptable values. Add each value on a separate line. Click OK to close the box.
- 4. Click Save to save and close the add window.

#### **Authorization Methods Tab**

The **Restrict Allowed Requesters** option is used to select Keyfactor Command security roles that a user must belong to in order to successfully enroll for certificates in Keyfactor Command using this template. This is typically used for EJBCA templates and Microsoft templates that are not in the local Active Directory forest, since in these cases, Keyfactor Command cannot make use of the access control model of the CA itself to determine which users can enroll for certificates; this setting replaces that functionality. This setting is similar to setting *request certificates* for the selected security roles at the template level on a Microsoft CA. For multi-forest environments, this setting should be used on any templates from forests other than the Keyfactor Command forest that will be used for enrollment regardless of the type of trust between the forests, including two-way trusts.

**Tip:** In addition to granting permissions at the template level, you may need to enable the **Restrict Allowed Requesters** option to grant permissions at the CA level (see <u>Adding or Modifying a CA Record on page 355</u>). This is generally only required for untrusted CAs (including CAs in a forest with a one-way trust with the forest in which the Keyfactor Command server is located), but may be needed for CAs in a forest with a two-way trust with the Keyfactor Command forest depending on the security configuration in the environment.

On the Authorization Methods tab you can add, edit and delete allowed requesters.

Figure 229: Certificate Template: Authorization Methods Tab

To add a new allowed requester, click to toggle the **Restrict Allowed Requesters** button and:

- 1. On the **Authorization Methods** tab of the selected template click **Add**. If there are existing requesters configured, they will appear in a list on this tab.
- 2. In the Security Role dropdown, select a Keyfactor Command security role (see <u>Security Roles</u> and <u>Claims on page 623</u>) to grant enrollment permissions on the template.
- 3. Click **Save** to save and close the add window.

#### Metadata Tab

From the **Metadata** tab you can:

- View the metadata field settings for that specific template.
- Configure how (or whether) the metadata fields will appear during enrollment for that specific template.

# **System-Wide Settings**

System-wide metadata fields are defined in System Settings (see <u>Certificate Metadata on</u> page 712) and displayed here.

#### **Template Settings**

Once the system-wide metadata has been defined, the **Enrollment Handling** setting can be configured on a template-specific basis, potentially overriding a system-wide *required*, *hidden or optional* setting for *that metadata field* on *that template*, causing only the set of fields configured for the template to appear on the PFX and CSR enrollment pages when the template is selected, and determining if they are required or optional.

**Tip:** This allows an administrator to apply *required*, *hidden or optional* settings to a metadata field on a per-template basis so that only certain metadata fields appear on certain templates. For example, if metadata fields A and B are set to *required* or *optional* and Metadata field C is set to *hidden* for the WebServer template, only A and B will appear during enrollment with that template.

A default value for a metadata field can also be configured that is different from, and overrides, the default value entered for the system-wide metadata field. For string metadata fields, a regular expression validation and error message can also be configured on a template-specific basis. The order in which the metadata fields appear can be changed globally (see <u>Sorting Metadata Fields on page 717</u>).

Figure 230: Certificate Template: Metadata Tab

The Metadata grid columns can be sorted by clicking the column heading (except Default Value). The columns are:

- Name: The name of the metadata field.
- Data Type: The metadata field type: String, Integer, Date, Boolean, Multiple Choice, or Big Text.
- **Enrollment Handling**: The handling of the metadata field during enrollment: *Optional, Required or Hidden*.
- Default Value: The default value during enrollment, if there is one, will be displayed.
- **Uses System-Wide Settings**: Displays *Yes* if system-wide settings are in effect for this template, or *No* if template-specifc settings are in effect.

To configure metadata fields for a template:

- On the Metadata tab, double-click a row in the metadata grid, right-click the row and choose
   Edit from the right-click menu, or highlight the row in the grid and click Edit at the top of the
   grid.
- 2. In the Metadata dialog in the *System-Wide Settings* section, review the existing system-wide settings for the metadata field.
- 3. In the *Template Settings* section, click to toggle the **Override system-wide settings** button. Configure the template-level settings for the metadata field. The available fields will vary depending on the type of the metadata field and may include:
  - Choose the Enrollment Options for this template by selecting the appropriate radio button:
    - a. **Optional**: The metadata field will appear during enrollment with this template, but it will not be required to complete enrollment.
    - b. **Required**: This field will be required in order to complete enrollment with this template.
    - c. **Hidden**: This field will not be displayed during enrollment with this template.
  - Set the *Default Value* if desired. If no default value is desired, the field may be left blank. For Multiple Choice type metadata fields, this field will appear as a dropdown where you can select from the existing values configured for the metadata field.
  - If desired, set a RegEx Message and RegEx Validation string specific to the template used to validate the value upon enrollment entry, and any error message to display if the entry does not match the regex definition. For more information, see <a href="Adding or Modifying">Adding or Modifying</a> a Metadata Field on page 712. This option is supported for string type metadata fields.
- 4. Click Save on the Metadata dialog to save changes for each metadata field.

#### **Enrollment Regexes Tab**

Enrollment Regexes can be applied at either the template-specifc level or system-wide level. Template-level regular expressions are used to validate that the certificate subject data entered on the CSR enrollment, CSR generation, and PFX enrollment pages meets certain criteria. Template-level regular expressions differ from system-wide regular expressions (see <a href="Configuring System-Wide Settings on page 383">Configuring System-Wide Settings on page 383</a>) as they apply on a per-template basis, rather than system-wide. In the case of a conflict in a regular expression between system-wide and template-level definitions, the template-level regular expression takes precedence.

**Tip:** To use a system-wide enrollment regular expression for a subject part and allow a specific template to bypass that regular expression, you can configure a template-level regular expression for the desired subject part and set it to no value.

Figure 231: Certificate Template: Enrollment RegExesTab

The Enrollment Regexes grid columns can be sorted by clicking the column heading (except Regex and Error). The columns are:

- Subject Part Full Name: The descriptive name of the certificate subject part (e.g. Common Name).
- **Subject Part**: The code for the certificate subject information part. For instance, CN=Common Name.
- RegEx: The regular expression to apply to the subject part.
- **Error**: The error message to display (upon **Save** when enrolling), when the entry does not meet the specified criteria.

• Uses System-Wide Settings: Displays Yes if system-wide settings are in effect for this template, or No if template-specific settings are in effect.

To configure template regular expression fields for a template:

- 1. On the Template Regexes tab, double-click a row in the regular expression grid, right-click the row and choose **Edit** from the right-click menu, or highlight the row in the grid and click **Edit** at the top of the grid.
- 2. In the Enrollment RegEx dialog in the *System-Wide Settings* section, review the existing system-wide settings for the subject part.
- 3. In the *Template Settings* section, click to toggle the **Override system-wide settings** button. Enter a regular expression in the **RegEx** field. See <u>Regular Expressions on page 403</u> for examples.
- 4. In the **Error** field enter the error message to display during enrollment if the data entered for the subject part does not meet the validation rule.
- 5. Click Save on the Enrollment RegEx dialog to save each template-level regular expression.

The regular expressions will be applied at the time of enrollment. Entries which do not match the regular expression requirements will be flagged with an error message during enrollment entry when you click **Enroll** (or **Generate** for CSR generation).

# PFX Enrollment 9

Complete the fields below and submit the form to enroll for a certificate and private key.

Figure 232: Certificate Template: Template Regular Expression Error on Enrollment

**Tip:** To prevent users from adding a given SAN field to a certificate, create a regular expression on the field with the following value:

^\$

This will disallow entry of any data in the SAN field and thus prevent users from submitting the certificate request with this SAN.

#### **Enrollment Defaults Tab**

Template-level enrollment defaults allow you to define default values for certificate subject parts that will auto-populate on the PFX enrollment and CSR generation pages in the Keyfactor Command Management Portal. Template-level default values differ from system-wide default values (see <a href="Configuring System-Wide Settings">Configuring System-Wide Settings</a> on page 383) as they apply on a per-template basis, rather than system-wide. In the case of a conflict in a default value between system-wide and template-level definitions, the template-level default values takes precedence.

**Note:** These default values will not be applied to the additional SANs fields in CSR Enrollment.

**Tip:** To use a system-wide enrollment default value in a subject part and allow a specific template to bypass that default value, you can configure a template-level default value for the desired subject part and set it to no value.

Figure 233: Certificate Template: Enrollment Defaults Tab

The Enrollment Defaults grid columns can be sorted by clicking the column heading (except Value). The columns are:

- Subject Part Full Name: The descriptive name of the certificate subject part (e.g. Common Name).
- **Subject Part**: The code for the certificate subject information part. For instance, CN=Common Name.
- Value: The default value to apply to the subject part.
- Uses System-Wide Settings: Displays Yes if system-wide settings are in effect for this template, or No if template-specific settings are in effect.

To configure template-level default values for a template:

- On the Enrollment Defaults tab, double-click a row in the defaults grid, right-click the row and choose Edit from the right-click menu, or highlight the row in the grid and click Edit at the top of the grid.
- 2. In the Enrollment Default dialog in the *System-Wide Settings* section, review the existing system-wide default value for the subject part.
- 3. In the *Template Settings* section, click to toggle the **Override system-wide settings** button. Enter a template-level default value for the subject part in the **Value** field.
- 4. Click Save on the Enrollment Default dialog to save each template-level default.

**Note**: Enrollment defaults do not apply to requests made with CSR enrollment or the Keyfactor API.

**Tip:** See also the *Subject Format* application setting, which takes precedence over enrollment defaults at both the system-wide and template level (see <u>Application Settings: Enrollment Tab on page 610</u> in the *Keyfactor Command Reference Guide*).

#### Policies Tab

The Policies Tab allows you to set template-level policy definitions which take precedence over system-wide settings (see Configuring System-Wide Settings on page 383).

**Note**: When a template is imported into Keyfactor Command, a default template policy is added. Similarly, if a template is updated and no policy exists, a default policy is saved for it. The default policies have null values for everything, and will not override the system-wide policies.

#### **Enrollment Policies**

The **Enrollment Policies** section displays the *System-Wide Setting* (*Yes* or *No*) for each of the template enrollment policies and allows you to **Override System-Wide Setting** for the specific template. Enabling **Override System-Wide Setting** will cause the system setting is to be disregarded and allow you to enable or disable the setting for that policy on the template. **Override System-Wide Setting** does not automatically set the policy to the opposite, the selection on the policy (enabled/disabled) will supersede any other settings.

Allow Wildcards

Enable this option to allow certificates to be created containing wildcards (e.g.

- \*.keyexample.com) using this template.
- · Allow Public Key Reuse

Enable this option to allow private keys to be reused on certificate renewals made using this template.

Enforce RFC 2818 Compliance

Enable this option to force certificate enrollments made through Keyfactor Command for this template to include at least one DNS SAN. In the Keyfactor Command Management Portal, this causes the CN entered in PFX enrollment to automatically be replicated as a SAN, which the user can either change or accept. For CSR enrollment, if the CSR does not have a SAN that matches the CN, one will automatically be added to the certificate if this is set.

**Tip:** For CA gateways, some cloud providers will automatically include SANs without you needing to enable the **Enforce RFC 2818 Compliance** option. Some cloud providers won't support submission of a SAN that matches the CN (which is the default when you enable the RFC 2818 option). Keyfactor recommends disabling this option for CA gateways.

#### **Supported Key Types**

The **Supported Key Types** section displays the *System-Wide Setting* (*value* or *Yes/No*) for the supported key type and allows you to Override System-Wide Setting for the specific template. Enabling **Override System-Wide Setting** will cause the system-wide setting to be disregarded, enable the settings field, and allow you to select the setting for that policy on the template. **Override System-Wide Setting** does not automatically set the policy to the opposite, the selection on the policy (values or enabled/disabled) will supersede any other settings.

**Note:** The supported key algorithms for a certificate template are determined based on the key size(s), type(s), and curve(s) returned for the template from the CA and the Keyfactor Command template policy settings at both the system-wide and template-specific levels.

Evaluation using both the CA configurations and the Keyfactor Command policy allows for a key size to be set on a template in Keyfactor Command for validation purposes that can be different than the CA template key size setting (perhaps the CA supports RSA 2048, RSA 4096, and ECC 256 for the template but the Keyfactor Command template-specific policy is set to disallow RSA and allow only ECC 256).

When configuring template-level policies for key information, only algorithms, sizes, and curves supported for the template by the CA will appear as options for configuration.

Depending on the template selected, one or more of these settings will be available for configuration:

# **RSA Key Sizes**

A list of RSA key sizes that are valid for enrollment through Keyfactor Command for this template. If a key size is not in this list, enrollment will not be supported for requests specifying that key size. To change the selected values, in the dropdown check any values you wish to support. The values supported by Keyfactor Command are: 2048, 3072, 4096, 6144, 8192, and 16384. Only values that are valid for the template on the CA will appear as available for selection.

# **ECC Curves**

A list of elliptic curve algorithms that are valid for enrollment through Keyfactor Command for this template. To change the selected values, in the dropdown check any values you wish to support. The values supported by Keyfactor Command are: P-256/prime256v1/secp256r1, P-384/secp384r1, and P-521/secp521r1. Only values that are valid for the template on the CA will appear as available for selection.

# Allow Ed448 for Template / Allow Ed25515 for Template

Enable or disable support for Ed448 or Ed25519 keys on the template.

Figure 234: Certificate Template: Policies Tab

**Tip:** Templates that are configured for CA-level key archiving are not supported for enrollment done through Keyfactor Command. For a Microsoft CA, this is the "Archive subject's encryption private key" setting on the template. For an EJBCA CA, this is the "Key Recoverable" setting on the end entity profile, which only appears if key recovery has been enabled in system configuration. An error similar to the following on enrollment is an indication that a Microsoft template is configured to archive the private key:

The request is missing a required private key for archival by the server.

For enrollments done through Keyfactor Command for either Microsoft or EJBCA CAs, use Keyfactor Command private key retention (see <u>Details Tab on page 388</u>).

# Viewing Template Certificates

To view the certificates in the Keyfactor Command database for a given template, highlight the template in the grid and click **View Certificates** at the top of the grid or right-click the template and choose **View Certificates** from the right-click menu. This will take you to the certificate search page with the query field populated by the selected template (see <u>Certificate Search Page on page 35</u>). You can save the search as a certificate collection at that point if desired (see <u>Saving Search Criteria</u> as a Collection on page 43).

# **Regular Expressions**

Several fields on the CSR enrollment, CSR generation, and PFX enrollment pages support using regular expressions to validate that the data entered in the fields meets certain criteria. Both

certificate subject fields and metadata string fields can be configured with regular expressions. The certificate subject fields that support regular expressions are shown in <u>Table 13: Supported Regular Expressions for Enrollment with Examples.</u>

Regular expressions for enrollment can be defined at a global level to apply to all enrollments and at a template level to apply only to enrollments done with that template. Template-level definitions take precedence over global definitions.

Both the regular expressions that do the validation and the error message that the user receives when the validation fails are user definable. For example, for the common name field you could define a regular expression similar to the following:

$$[a-zA-Z0-9'_\.-]*\.keyexample\.com$$$

This regular expression specifies that the data entered in the field must consist of some number of characters in the first portion of the field made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly .keyexample.com. Using this regular expression would prevent users from requesting certificates with common names such as myserver.contoso.com, forcing them to request certificates for domain names that are valid for your organization. Your error message to the user in this case might be something like:

Common names must end with keyexample.com.

The error message to the user appears immediately once the user leaves the field being validated after entering data that doesn't meet the regular expression requirements.

Table 13: Supported Regular Expressions for Enrollment with Examples

Subject Part	Example	
CN (Common Name)	This regular expression specifies that the data entered in the field must consist of some number of characters in the first portion of the field made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly .keyexample.com:	
	^[a-zA-Z0-9'_\.\-]*\.keyexample\.com\$	
	The default value for the Common Name regular expression is:	
	.+	
	This requires entry of at least one character in the Common Name field in the enrollment pages.	
O (Organization)	This regular expression requires that the organization name entered in the field be one of "Key Example Inc", "Key Example" or "Key Example Inc.":	
	^(?:Key Example Inc Key Example Key Example, Inc\.)\$	

Subject Part	Example
	The period in the final company name (Key Example, Inc.) needs to be escaped in the regular expression with a slash ("\") but the comma does not.
OU (Organization Unit)	This regular expression requires that the organizational unit entered in the field be one of these four departments:
	^(?:IT HR Accounting E-Commerce)\$
L (City/Locality)	This regular expression requires that the city entered in the field be one of these five cities:
	^(?:Boston Chicago New York London Dallas)\$
ST (State/Province)	This regular expression requires that the state entered in the field be one of these eight states:
	^(?:Massachusetts Illinois New York Ontario Texas)\$
C (Country)	This regular expression requires that the country entered in the field be either US or CA:
	^(?:US CA)\$
E (Email)	This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly "@keyexample.com":
	^[a-zA-Z0-9'_\.\-]*@keyexample\.com\$
DNS (Subject Alternative Name: DNS Name)	This regular expression specifies that the data entered in the field must consist of some number of characters in the first portion of the field made up only of lower-case letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly either ".keyexample1.com" or ".keyexample2.com":
	^[a-zA-Z0-9'_\.\-]*\.(?:keyexample1\.com keyexample2\.com)\$
IPv4 (Subject Alternative Name: IPv4 Address)	This regular expression specifies that the data entered in the field must be exactly "130.101." followed by anywhere between 1 and 3 numbers followed by exactly "." followed by anywhere between 1 and 3 numbers:
	^130\.101\.(?:[0-9]{1,3})\.(?:[0-9]{1,3})\$
	This regular expression specifies only that the IPv4 address is made up of 4 sets of between 1 and 3 numbers separated by periods:

Subject Part	Example
	^(?:[0-9]{1,3}\.){3}[0-9]{1,3}\$
IPv6 (Subject Alternative Name: IPv6 Address)	This regular expression specifies that the data entered in the field must be made up of eight sets of between one and four numbers and/or uppercase letters separated by colons:
	^(?:[A-F0-9]{1,4}:){7}[A-F0-9]{1,4}\$
MAIL (Subject Alternative Name: Email)	This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly "@keyexample.com":  ^[a-zA-Z0-9'_\.\-]*@keyexample\.com\$
UPN (Subject Alternative Name: User Principal Name)	This regular expression specifies that the data entered in the field must consist of some number of characters prior to the "@" made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly "@keyexample.com":
	^[a-zA-Z0-9'_\.\-]*@keyexample\.com\$

# PFX Enrollment 9

Complete the fields below and submit the form to enroll for a certificate and private key.

Certificate Subject Information:

Common Name: Common name must end with keyxample.com.

Organizational Unit: OU must be one of IT, HR, Accounting, or E-Commerce.

Organization: Organization must be Key Example, Inc or Key Example Company.

City/Locality: City must be one of Los Angeles, San Francisco, Seattle, Dallas, New York, Chicago, Vancouver or Toronto.

State/Province: State must be one of California (CA), Washington (WA), Texas (TX), New York (NY), Illinois (IL), British Columbia (BC) or Ontario (ON).

Country/Region: Country must be CA or US.

Email: Email must end with keyxample.com and can only contain letters, numbers, apostrophes, underscores, periods and dashes.

Certificate Metadata:

AppOwnerEmailAddress: Email addresses must be of the form user@keyexample.com or fname.lname@keyexample.com.

Figure 235: PFX Enrollment Regular Expression Validation Error

For more information about configuring regular expressions on metadata fields, see <u>Certificate Metadata on page 712</u>.

# Using the Template Search Feature

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an is null or is not null comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

Each query consists of three parts:

# **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

course to accu. On this page, the queries can be done on the following bank in holds.		
DisplayName	ShortName	
Complete or partial matches with the name of the template Display Name.	Complete or partial matches with the template Short Name.	
AllowedEnrollmentType	HasPrivateKeyRetention	
Complete or partial matches with allowed enrollment types on the template.	Private Key Retention is selected for this template (true/false).	
IsDefaultTemplate	ForestRoot	
The template is one of the Microsoft default templates (true/false). This is helpful to filter out the templates that you did/didn't create.	Complete or partial matches with the forest location.	
ConfigurationTenant	Note: This will be deprecated in a future release and replaced with Config-	

urationTenant.

Complete or partial matches with the Configuration Tenant name.

#### FriendlyName

Complete or partial matches with the Keyfactor Command friendly name of the template.

# Comparison Operator

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Contains (-contains)
- Does not contain (-notcontains)

## Most date and integer fields support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Is less than (-It)
- Is less than or equal to (-le)

# Most Boolean (true/false) fields support:

- Is equal to (-eq)
- Is not equal to (-ne)

- Starts with (-startswith)
- Ends with (-endswith)
- Is null (-eq NULL)
- Is not null (-ne NULL)
- Is greater than (-gt)
- Is greater than or equal to (-ge)
- Is null (-eq NULL)
- Is not null (-ne NULL)
- Is null (-eq NULL)
- Is not null (-ne NULL)

# Comparison Value

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

- Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.
- Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

# **Advanced Searches**

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

#### **Multiple Criteria**

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click **Insert** to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

#### 2.1.8.3 Certificate Stores

The certificate store feature in Keyfactor Command allows you to search for and inventory certificates from multiple types of certificate stores, import the certificates found in them into the Keyfactor Command database, add new certificates to the stores, and remove certificates from them. This feature uses Keyfactor orchestrators to communicate with the Keyfactor Command server. This section of the documentation describes the management tasks that can be done through the Management Portal. For information about installing and configuring the Keyfactor Universal Orchestrator, see the *Keyfactor Orchestrators Installation and Configuration Guide*.

Certificate stores are managed by configuring the store locations through the Management Portal, assigning an inventory schedule, and optionally assigning stores to containers (groups) for ease of management. You can create records for stores in the Management Portal manually or by using the discovery feature. Not all certificate store types support discovery; check the details of the certificate store types or any custom-built extensions you're using to determine whether discovery is supported.

Managing certificate stores requires that an appropriate instance of a Keyfactor orchestrator is running in the environment and has been approved in the Management Portal (see Orchestrator Management on page 497). Java and PEM certificate stores can be managed with an instance of the Keyfactor Java Agent running on the machine where the Java and PEM certificate stores are located or with the Keyfactor Universal Orchestrator and the Keyfactor Remote File extension. Amazon Web Services (AWS), F5, Citrix/NetScaler, Windows (IIS) certificate stores and more can be managed with the Keyfactor Universal Orchestrator and an appropriate Keyfactor custom-built extension. Keyfactor offers many custom-built extensions for the Keyfactor Universal Orchestrator on GitHub:

https://keyfactor.github.io/integrations-catalog/content/orchestrator

Some packages that may be of special interest to long-term users of Keyfactor Command are:

- AWS Certificate Store Manager
- Citrix NetScaler Certificate Store Manager
- F5 Certificate Store Manager
- IIS Certificate Store Manager
- Remote File Certificate Store Management (Java Keystores, PKCS12 files, PEM files, DER files, IBM Key Database files)

Once your certificate stores have been inventoried and their certificates imported into Keyfactor Command, you can use the standard Management Portal features for managing certificates—such as Expiration Alerts (see Expiration Alerts on page 167)—to manage the certificates from the certificate store locations even if the certificates were not generated by your Keyfactor Command configured CAs.

Most certificate store types can use **Privileged Access Management (PAM)** or **Keyfactor Secrets** to manage passwords for the servers or devices on which the certificates stores are located and on the certificate stores themselves, where applicable.

# F5 and IIS Certificate Store Terminology

This section uses the following terminology for F5 and IIS certificate stores:

#### F5 CA Bundles REST

Certificates and keys for the F5 CA Bundles REST are those found within F5 Bundles. Note that the ca-bundle cannot be managed with Keyfactor Command, as it is protected and managed directly by F5. Only the Include Bundles may be managed with this option. This option uses the F5 iControl REST API. It is intended to be used with BIG-IP versions 13 and later. The F5 CA Bundles REST option supports certificate discovery on the F5 device and F5 high availability.

# F5 SSL Profiles

Certificates and keys for the F5 SSL Profiles are those used by any applications configured for use by the F5 device. These are certificates that are available in the F5 interface as the SSL certificate list. This option uses the F5 SOAP API. It is intended to be used with BIG-IP version 12.

#### F5 SSL Profiles REST

Certificates and keys for the F5 SSL Profiles REST are those used by any applications configured for use by the F5 device. These are certificates that are available in the F5 interface as the SSL certificate list. This option uses the F5 iControl REST API. It is intended to be used with BIG-IP versions 13 and later. The REST version of F5 SSL Profiles supports certificate discovery on the F5 device and F5 high availability.

### F5 Web Server

#### F5 Web Server REST

Certificates and keys for the F5 Web Server REST are those used by the device itself for the F5 portal and the API. This certificate is referred to as the device certificate within the F5 interface. This option uses the F5 iControl REST API. It is intended to be used with BIG-IP versions 13 and later. The F5 Web Server REST option supports F5 high availability.

#### **IIS Revoked**

The Untrusted Certificates store of the local computer.

#### **IIS Trusted Roots**

The Trusted Root Certification Authorities store of the local computer.

#### IIS Personal

The Personal store of the local computer.

Certificates and keys for the *F5 Web Server* are those used by the device itself for the F5 portal and the SOAP API. This certificate is referred to as the *device certificate* within the F5 interface. This option uses the F5 SOAP API. It is intended to be used with BIG-IP version 12.

**Tip:** Click the help icon (②) next to the page title to open the embedded web copy of the *Keyfactor Command Documentation Suite* to this section.

You can also find the help icon at the top of the page next to the **Log Out** button. From here you can choose to open either the *Keyfactor Command Documentation Suite* at the home page or the *Keyfactor API Endpoint Utility*.

# **Using the Certificate Store Search Feature**

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an *is null* or *is not null* comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

Each query consists of three parts:

# **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

AgentAvailable	Container
Orchestrator has been approved and made available to manage certificate store jobs (true/false).	Complete or partial matches with one or more certificate store containers.
AgentID	HasInventoryScheduled
Orchestrator Id matches or doesn't match the entered GUID (primarily used for internally generated searches when the user is redirected here	Certificate store has an inventory job scheduled (true/false).
from another page).	StorePath
Category	Complete or partial matches with the full path to a certificate store—e.g. /opt/application/mystore.crt
Certificate store matches or doesn't match the referenced category. Categories include (plus categories from custom certificate store types	or c:\program files\application\mystore.jks.

you've entered):

- · Amazon Web Services
- F5 CA Bundles REST
- F5 SSL Profiles
- F5 SSL Profiles REST
- F5 Web Server
- F5 Web Server REST
- File Transfer Protocol
- IIS Personal
- IIS Revoked
- IIS Roots
- Java Keystore
- NetScaler
- PEM File

#### ClientMachine

Complete or partial matches with the client machine(s) on which a store or stores may be found.

# **Comparison Operator**

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Contains (-contains)
- Does not contain (-notcontains)

- Starts with (-startswith)
- Ends with (-endswith)
- Is null (-eq NULL)
- Is not null (-ne NULL)

Most date and integer fields support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Is less than (-It)
- Is less than or equal to (-le)

- Is greater than (-gt)
- Is greater than or equal to (-ge)
- Is null (-eq NULL)
- Is not null (-ne NULL)

Most Boolean (true/false) fields support:

- Is equal to (-eq)
- Is not equal to (-ne)

- Is null (-eq NULL)
- Is not null (-ne NULL)

# Comparison Value

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

- Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.
- Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

Figure 236: Simple Certificate Store Search

The search results can be sorted by clicking on a column header in the results grid for every column except Inventory Schedule and Orchestrator Available. Click the column header again to reverse the sort order. The grid columns can be arranged in any order desired by click-holding and dragging the header of the column you wish to move. The column widths may be adjusted by click-holding and dragging the line separating two column headers.

#### **Advanced Searches**

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

# Multiple Criteria

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click Insert to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND
TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template referencing web. When you have entered all the desired search criteria, click Search to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

# **Certificate Store Operations**

To select a single row in the certificate store grid, click to highlight it and then select an operation from either the top of the grid or the right-click menu. The delete, schedule inventory and assign container operations can be done on multiple certificate stores at once. To select multiple rows, click the checkbox for each row on which you would like to perform an operation. Then select an operation from the top of the grid. The selected stores must all be of the same category (e.g. PEM or Java) to perform the assign container operation. The right-click menu supports operations on only one store at a time.

# Adding or Modifying a Certificate Store

Before creating a certificate store in Keyfactor Command, you must approve an orchestrator to handle the store (see Approving or Disapproving Orchestrators on page 501).

Tip: The following permissions (see Security Roles and Claims in the Keyfactor Command Reference Guide) are required to use this feature:

Agents > Management > Read Certificate Stores > Read Certificate Stores > Modify

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions in the Keyfactor Command Reference Guide for more information about global vs container permissions.

Certificate stores can be added manually or, for some types of stores, automatically using a discover process (see Certificate Store Discovery on page 438).

**Note**: A user with the appropriate permissions may create more than one certificate store in a given location provided the stores are of different categories/types. Stores of the same type should still fail to be saved using the same target.

To define a new certificate store location manually or edit an existing one:

- 1. In the Management Portal, browse to *Locations > Certificate Stores*.
- 2. On the Certificate Stores page, select the Certificate Stores tab (the default when you first visit the page).
- 3. On the Certificate Stores tab, click **Add** to create a new store location, or click **Edit** from either the top or right-click menu to modify an existing one.
- 4. In the Certificate Stores dialog, select the type of certificate store in the **Category** dropdown. The values that appear here are the display names for the built-in certificate store types and any custom certificate store types you entered to match your custom extensions. Examples of Keyfactor-provided custom-built extensions on GitHub include:
  - AWS Certificate Store Manager
  - Citrix NetScaler Certificate Store Manager
  - F5 Certificate Store Manager
  - IIS Certificate Store Manager
  - Remote File Certificate Store Management (Java Keystores, PKCS12 files, PEM files, DER files, IBM Key Database files)

Note: This field cannot be modified on an edit.

Figure 237: Add a Remote JKS Certificate Store

- 5. In the **Container** field, select a container into which to place the store for organization from your previously defined list, if desired. This field is optional. If no container matching the type of certificate store you are adding exists, no containers will be available in the dropdown (see <u>Certificate Store Container Operations on page 436</u>). Leave blank if you do not wish the certificate store to be associated with a specific store container.
- 6. The remaining fields on the dialog will vary depending on the configuration of your custom certificate store type. Common fields include:

#### • Client Machine

Typically the fully qualified domain name or IP address of the target server or device on which the certificate store is located.

Important: In some cases, it's necessary to use the actual hostname of the target server in the Client Machine field rather than a DNS alias (either "A" or CNAME records). This is necessary when the orchestrator uses PowerShell remoting (WinRM) for some of the machine certificate store functions, which relies on Kerberos authentication. Kerberos authentication requires that the target machine has a service principal name (SPN) in the HTTP/ format assigned to the target's machine account. This will be present by default (as part of the HOST/ format record) as long as the HTTP/ format SPN has not been manually assigned elsewhere. Using an alias gets into complexities of setting up appropriate SPNs and assuring that there are not duplicate SPNs in the environment. If you wish to manage the target server hosting Keyfactor Command, you will need to use a DNS alias for either your Keyfactor Command server or the IIS store access. Contact Keyfactor for design assistance.

Note: This field cannot be modified on an edit.

#### Store Path

The path to the certificate store, sometimes including the store file name, on the target server or device.

For Java keystores, for example, this would be a file system path and file name (e.g. /opt/app/mystore.jks or C:\My App\mystore.jks). Paths and filenames entered for Linux/UNIX machines are case sensitive.

For CA bundles on F5 devices, this is the bundle into which you want to install the certificate (e.g. /Common/myca-bundle). The Store Path name is case sensitive for some targets and devices, so, for example, if the partition name on the F5 is *Common* it must be entered in the Store Path field as *Common* rather than *common*.

For IIS bound certificate stores, this is the name of the Windows certificate store (My = Local Computer *Personal* store, Web Hosting = Local Computer *Web Hosting* store).

Check the details of the documentation for your custom-built extension to determine the data to enter here.

Note: This field cannot be modified on an edit.

#### Orchestrator

The name that the Keyfactor Universal Orchestrator used when registering with Keyfactor Command. The orchestrator must be approved in order to appear here (see <u>Approving or Disapproving Orchestrators on page 501</u>).

#### • Server Username

The source from which to load a user valid on the target server or device with sufficient permissions to read the store location and open the file(s) and the name of that user, if applicable. In the Server Username dialog, the options are Load From Keyfactor Secrets or Load From PAM Provider. The *No Value* option is typically not supported for server authentication.

For F5, this as a user with Administrator permissions. Although a user with Resource Administrator permissions is sufficient when using the F5 methods that use the SOAP API, the F5 methods that use the REST API require full Administrator permissions.

For AWS using IAM authentication, this is the API access key for your web service.

This field only appears if your custom certificate store type indicates that it Needs Server.

#### Server Password

The source from which to load a valid password for the user used to access the server and the password for that user, if applicable. In the Server Password dialog, the options are Load From Keyfactor Secrets or Load From PAM Provider. The *No Value* option is typically not supported for server authentication.

This field only appears if your custom certificate store type indicates that it Needs Server.

Figure 238: Set Password Dialog

A Keyfactor secret is a user-defined password or other information that is encrypted and stored securely in the Keyfactor Command database. Although Keyfactor recommends

using Privileged Access Management (see <u>Privileged Access Management (PAM) on page 744</u>) as a more secure solution to secure information, Keyfactor Secret is an option for customers that do not already have a relationship with a PAM provider such as CyberArk or Delinea.

Important: Keyfactor highly recommends that you use strong passwords for any accounts or certificates related to Keyfactor Command and associated products, especially when these have elevated or administrative access. A strong password has at least 12 characters (more is better) and multiple character classes (lower-case letters, uppercase letters, numeral, and symbols). Ideally, each password would be randomly generated. Avoid password re-use.

Select the **Load From Keyfactor Secrets** radio button as the *Secret Source* if you want Keyfactor Command to encrypt and store the password in the Keyfactor Command database. Enter and confirm a password.

Select the **Load from PAM Provider** radio button as the *Secret Source* if you want to store the password in a supported third-party PAM solution (see <u>Privileged Access Management (PAM) on page 744</u>). The remaining fields on the dialog will vary depending on the PAM provider. For example:

## CyberArk

Select your CyberArk provider in the **Providers** dropdown if your PAM provider is CyberArk (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining fields in the dialog will then be:

- Safe—The name of the safe the credential resides in.
- Object—The name of the username or password object in the safe.
- Folder—The path and name of the folder that stores the object (e.g. Root or Root\MyDir).

#### Delinea

Select your Delinea provider in the **Providers** dropdown if your PAM provider is Delinea (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining field in the dialog will then be:

- Secret Server Secret ID—The numeric ID of the secret to retrieve from Secret Server
- Secret Field Name—The name of the field to use when retrieving a secret form Secret Server.

## Hashicorp

Select your Hashicorp Vault provider in the **Providers** dropdown if your PAM provider is Hashicorp Vault (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining field in the dialog will then be:

- ° KV Secret Key—The key of the secret to retrieve from the Hashicorp Vault.
- KV Secret Name—The name of the secret to retrieve from the Hashicorp Vault.

#### Use SSL

Use SSL to communicate to the remote target or device.

If the remote target is an F5 device and you're using the F5 extension, the device must trust the CA that issued the certificate used to protect the Keyfactor Command server or you must set the *Ignore Server SSL Warnings* application setting to *True* (see <u>Application Settings</u>: Agents Tab on page 615).

If the remote target is a Windows server and you're using the Remote File or IIS extension, WinRM on the target must be configured to support HTTPS and have been configured with an SSL certificate (see *Configure Windows Targets for Remote Management* in the *Keyfactor Orchestrators Installation and Configuration Guide*).

This field only appears if your custom certificate store type has been configured with the *Use SSL* custom field. Your field name may vary depending on the configuration of your custom certificate store type.

#### Create Certificate Store

If this box is checked, a new certificate store will be created on the target with the specified configuration. This option only appears if your custom certificate store type has been configured with Create for *Supported Job Types*.

#### Store Password.

The source from which to load a valid password for the certificate store itself rather than the server as a whole. In the Store Password dialog, the options are No Value, Load From Keyfactor Secrets, and Load From PAM Provider.

Select No Value if your certificate store does not have a password configured.

A Keyfactor secret is a user-defined password or other information that is encrypted and stored securely in the Keyfactor Command database. Although Keyfactor recommends using Privileged Access Management (see <a href="Privileged Access Management (PAM)">Privileged Access Management (PAM)</a> on <a href="Page 744">Page 744</a>) as a more secure solution to secure information, Keyfactor Secret is an option for customers that do not already have a relationship with a PAM provider such as CyberArk or Delinea.

**Important:** Keyfactor highly recommends that you use strong passwords for any accounts or certificates related to Keyfactor Command and associated products, especially when these have elevated or administrative access. A strong password

has at least 12 characters (more is better) and multiple character classes (lower-case letters, uppercase letters, numeral, and symbols). Ideally, each password would be randomly generated. Avoid password re-use.

Select the **Load From Keyfactor Secrets** radio button as the *Secret Source* if you want Keyfactor Command to encrypt and store the password in the Keyfactor Command database. Enter and confirm a password.

Select the **Load from PAM Provider** radio button as the *Secret Source* if you want to store the password in a supported third-party PAM solution (see <u>Privileged Access Management (PAM) on page 744</u>). The remaining fields on the dialog will vary depending on the PAM provider. For example:

## CyberArk

Select your CyberArk provider in the **Providers** dropdown if your PAM provider is CyberArk (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining fields in the dialog will then be:

- ° Safe—The name of the safe the credential resides in.
- Object—The name of the username or password object in the safe.
- Folder—The path and name of the folder that stores the object (e.g. Root or Root\MyDir).

#### Delinea

Select your Delinea provider in the **Providers** dropdown if your PAM provider is Delinea (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining field in the dialog will then be:

- Secret Server Secret ID—The numeric ID of the secret to retrieve from Secret Server.
- Secret Field Name—The name of the field to use when retrieving a secret form Secret Server.

### Hashicorp

Select your Hashicorp Vault provider in the **Providers** dropdown if your PAM provider is Hashicorp Vault (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining field in the dialog will then be:

- KV Secret Key—The key of the secret to retrieve from the Hashicorp Vault.
- ° KV Secret Name—The name of the secret to retrieve from the Hashicorp Vault.
- Type

For Java keystores using the Keyfactor Java Agent, select the Type from the dropdown. The available types are:

JKS

Standard Java keystore.

° PKCS12

PKCS12 type files (e.g. P12 or PFX), which are discoverable with the Keyfactor Java Agent using compatibility mode introduced in Java version 1.8.

Windows-My

Windows local machine personal certificate store. This option is only supported with a custom extension based on the AnyAgent framework. The Keyfactor Java Agent does not include functionality to manage this type of store.

The dialog may present additional fields depending on the configuration of the Custom Fields for the certificate store type. Some additional fields that you may find for common Keyfactor custom-built extensions include:

• For F5 certificates stores, in the **Primary Node** field, enter the fully qualified domain name of the F5 device that acts as the primary node in a highly available F5 implementation. If you're using a single F5 device, this will often be the same value you entered in the Client Machine field.

**Tip:** Configuration of the primary node is necessary to allow management jobs that update certificates on the F5 device to wait until the primary node is available before making their update. Inventory jobs are carried out against any available node.

- For F5 certificates stores, in the Primary Node Check Retry Wait Seconds field, either
  accept the default value of 120 seconds or enter a new value. This value represents the
  number of seconds the orchestrator will wait after a pending management job cannot be
  completed because the primary node cannot be contacted before trying to contact the
  primary node again to retry the job.
- For F5 certificates stores, in the **Primary Node Check Retry Maximum** field, either accept the default value of 3 retry attempts or enter a new value. This value represents the number of times the orchestrator will retry a pending management job that is failing because the primary node cannot be contacted before declaring the job failed.
- For F5 certificates stores, in the **Version of F5** dropdown, select the version of F5 this server is running. The F5 REST API is supported on version 13 and up.

**Tip:** Select v15 for version 15 and above.

 For IIS bound and Windows certificate stores, in the WinRm Protocol field, select http to communicate between the orchestrator and the target over a non-secured WinRM channel or https to communicate over a secured channel WinRM channel. Using HTTPS for WinRM requires that the target has been configured to support HTTPS and has been configured with an SSL certificate for WinRM. For example:

https://learn.microsoft.com/en-us/troubleshoot/windows-client/system-manage-ment-components/configure-winrm-for-https

- For IIS bound and Windows certificate stores, in the **WinRm Port** field, accept the default of port 5986 for HTTPS, enter port 5985 for the default HTTP WinRM port, or enter an alternate port if your WinRM configuration is using an alternate port.
- For IIS bound and Windows certificate stores, in the **SPN with Port field**, accept the default of false unless you're aware that the -IncludePortwithSPN switch is required for remote PowerShell connections in your environment.
- For Java keystores, PEM stores, and PKCS12 stores on Linux targets when creating a
  new certificate store (see *Create Certificate Store*) using the Remote File extension, in
  the Linux File Permissions on Store Creation field, set the file permissions that should be
  granted to the new certificate store given in numeric format (e.g. 644). The default is
  600.
- For Java keystores, PEM stores, and PKCS12 stores on Linux targets when creating a
  new certificate store (see Create Certificate Store) using the Remote File extension, in
  the Linux File Owner on Store Creation field, set the file ownership that should be
  granted to the new certificate store given as a Linux username. The default is the user
  configured to authenticate to the server (see Server Username).
- For PEM stores, in the **Separate Private Key File Location** field, enter the full path to the private key on the machine, including the file name. Paths and filenames entered for Linux/UNIX machines are case sensitive.
- For PEM stores using the Remote File extension, in the **Trust Store** field, a value of True indicates the target store is a trust store and as such should only contain public keys. If a store is marked as a trust store and a job is run that attempts to add a private key for a certificate to the store, an error will occur indicating a problem. A value of False indicates the store can contain a single certificate with private key and chain. The default is False.
- For PEM stores using the Remote File extension, in the **Store Includes Chain** field, a value of True causes the full chain for the certificate to be delivered to the store. A value of False indicates that only the certificate and private key should be delivered to the store. The certificates are always placed in the store in the order of: End Entity, Issuing CA, Root CA. The default is False. The field is ignored if *Trust Store* is True.
- For PEM stores using the Remote File extension, in the Is RSA Private Key field, a value of
  True indicates the private key for the certificate store is a PKCS#1 RSA formatted key (it
  will be headed with a line that reads "BEGIN RSA PRIVATE KEY"). A value of False indicates the private key for the certificate store is either an encrypted or non-encrypted
  PKCS#8 formatted key (it will be headed with a line that reads either
  "BEGIN PRIVATE KEY" or "BEGIN ENCRYPTED PRIVATE KEY"). If set to True, the Store

Password must be set to No Value. The default is False. The field is ignored if Trust Store is True.

- 7. In the Inventory Schedule fields, select an inventory schedule for the store, if desired. You can choose to run the inventory Daily, on an Interval, Immediately, Exactly Once, or set inventorying to Off.
  - If you select Daily, you can set the time of day when the inventory should begin every day.
  - If you select Interval, you can select a scan frequency of anywhere from every 1 minute to every 12 hours.
  - If you select Immediate, the inventory will run within a few minutes of saving the record and will run only once. After this, the inventory schedule will be cleared.
  - · If you select Exactly Once, you can select a date and time at which to run the inventory job. After the job has run, the inventory schedule will be cleared.
  - · Select Off to disable the inventory job.

If you are using Certificate Store Containers (see Certificate Store Containers on page 433) to manage your stores and their schedules you do not need to set an inventory schedule here.

8. Click **Save** to save the new or edited certificate store location.

## **Deleting a Certificate Store**

Tip: The following permissions (see Security Roles and Claims in the Keyfactor Command Reference Guide) are required to use this feature:

Certificate Stores > Read Certificate Stores > Modify

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions in the Keyfactor Command Reference Guide for more information about global vs container permissions.

To delete a certificate store:

- 1. In the Management Portal, browse to *Locations > Certificate Stores*.
- 2. On the Certificate Stores page, select the Certificate Stores tab (the default when you first visit the page).
- 3. On the Certificate Stores tab, highlight the row(s) in the certificate store grid of the store(s) to delete and click Delete at the top of the grid or right-click the store location in the grid and choose **Delete** from the right-click menu. The right-click menu supports operations on only one store at a time.
- 4. On the Confirm Operation alert, click **OK** to confirm or **Cancel** to cancel the operation.

Note: This doesn't delete the actual certificate store on the target server, just the Keyfactor Command definition of it.

## **Viewing a Certificate Store**

Users without modify permissions to certificate stores will see a *View* option instead of an *Edit* option on the Certificate Stores page to allow them to see a read-only view of the certificate store configuration details.

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Agents > Management > Read Certificate Stores > Read

Permissions for certificate stores can be set at either the global or certificate store container level. See *Container Permissions* in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

To view the details of a certificate store:

- 1. In the Management Portal, browse to Locations > Certificate Stores.
- 2. On the Certificate Stores page, select the Certificate Stores tab (the default when you first visit the page).
- 3. On the Certificate Stores tab, highlight the row in the certificate store grid of the store for which to view certificate store details and click **View** at the top of the grid or right-click the store location in the grid and choose **View** from the right-click menu.

The fields are the same as those described for adding or editing a certificate store (see <u>Adding or Modifying a Certificate Store on page 414</u>), but none of the fields are editable when using the *View* option.

Figure 239: View Details for a Certificate Store

### **Certificate Store Reenrollment**

The Reenrollment option is available for select built-in and custom-built extensions provided by Keyfactor on GitHub or can be included in your fully custom extension. Examples of built-in and Keyfactor custom-built extensions that support reenrollment include:

- Akamai Certificate Provisioning System (CPS) on GitHub for use with the Keyfactor Universal Orchestrator
- IIS Certificate Store Manager on GitHub for use with the Keyfactor Universal Orchestrator
- PEM and Java certificate stores managed by the Keyfactor Java Agent.

Tip: The following permissions (see Security Roles and Claims in the Keyfactor Command Reference Guide) are required to use this feature:

Certificates > Enrollment > CSR

Certificate Stores > Read

Certificate Stores > Modify

Permissions for certificate stores can be set at either the global or certificate store container level. See Container Permissions in the Keyfactor Command Reference Guide for more information about global vs container permissions.

In addition, either the user scheduling the reenrollment job or the user configured to provide authentication to the CA (see Authorization Methods Tab on page 368) must have enrollment permissions configured on the CA and template.

### To begin a reenrollment:

- 1. In the Management Portal, browse to *Locations > Certificate Stores*.
- 2. On the Certificate Stores page, select the Certificate Stores tab (the default when you first visit the page).
- 3. On the Certificate Stores tab, highlight the row in the certificate store grid of the store to reenroll and click Reenrollment at the top of the grid or right-click the store location in the grid and choose Reenrollment from the right-click menu.
- 4. On the Reenrollment dialog, enter a Subject Name for the new certificate using X.500 format and populate any additional fields as required by the certificate store type (on the Entry Parameters tab; see Adding or Editing a Certificate Store Type on page 703).
- 5. If desired, select a Certificate Authority to direct the enrollment request to and/or Template for the request. In the Template dropdown, only templates that are available for enrollment from the selected certificate authority will appear.

Note: If you don't select a template or CA for reenrollment, the values configured for the Template For Submitted CSRs and/or Certificate Authority For Submitted CSRs application setting(s) (see Application Settings: Agents Tab on page 615) will be used.

Tip: If an expected template does not appear in the Template dropdown, confirm that it is available for enrollment from the selected CA, has been configured for CSR enrollment in Keyfactor Command, and has appropriate enrollment permissions at the Keyfactor Command, CA and template level for the user making the reenrollment request or relevant service account depending on the authorization method for enrollment (see Grant the Keyfactor Command Users and Service Account(s) Permissions on the CAs in the Keyfactor Command Server Installation Guide).

6. Click Done to submit the request.

The reenrollment job will be scheduled to run immediately. Visit the Orchestrator Jobs page to check on the progress of the job (see Orchestrator Job Status on page 511).

Figure 240: Enter a Information for Reenrollment

### Setting a New Password on a Certificate Store

The option to reset the password on a certificate store updates the data for the certificate store as stored in the Keyfactor Command database but does not make any modifications to the certificate store itself. This option is available from the right-click menu only.

**Tip**: The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Certificate Stores > Read Certificate Stores > Modify

Permissions for certificate stores can be set at either the global or certificate store container level. See *Container Permissions* in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

To reset the password for a certificate store:

- 1. In the Management Portal, browse to Locations > Certificate Stores.
- 2. On the Certificate Stores page, select the Certificate Stores tab (the default when you first visit the page).

- 3. On the Certificate Stores tab, highlight the row in the certificate store grid of the store to update and choose **Set New Password** from the right-click menu.
- 4. Enter and confirm the new password and click Save.

## Assigning a Certificate Store to a Container

Before assigning a certificate store to a container, you need to create the container (see <u>Certificate Store Containers on page 433</u>). If you select multiple certificate stores to assign to a container at once, they must all be stores of the same type (e.g. PEM).

**Tip**: The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Certificate Stores > Read Certificate Stores > Modify

Permissions for certificate stores can be set at either the global or certificate store container level. See *Container Permissions* in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

To assign a certificate store to a container:

- 1. In the Management Portal, browse to *Locations > Certificate Stores*.
- 2. On the Certificate Stores page, select the Certificate Stores tab (the default when you first visit the page).
- 3. On the Certificate Stores tab, highlight the row(s) in the certificate store grid of the store(s) to be assigned to the container and click **Assign Container** at the top of the grid or right-click the store location in the grid and choose **Assign Container** from the right-click menu. The right-click menu supports operations on only one store at a time.
- 4. Select a certificate store container in the Container Name field and click Save.

## Viewing Inventory for a Certificate Store

Once at least one inventory job has been completed for a given certificate store, you can view the certificates imported from the store.

**Tip**: The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

PAM > Read Certificate Stores > Read Certificate > Collections > Read

Permissions for certificate stores can be set at either the global or certificate store container level. See *Container Permissions* in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

To view the inventoried certificates for a store:

- 1. In the Management Portal, browse to *Locations > Certificate Stores*.
- 2. On the Certificate Stores page, select the Certificate Stores tab (the default when you first visit the page).
- 3. On the Certificate Stores tab, highlight the row in the certificate store grid of the store for which to view inventory and click **View Inventory** at the top of the grid or right-click the store location in the grid and choose **View Inventory** from the right-click menu.

On the left of the inventory viewing dialog you can select a certificate from the store to view. On the right of the dialog you can see details about that certificate, including the metadata associated with the certificate. In the Certificate Selection area of the screen, you can select between the chain certificates for the selected certificate and the end entity certificate, for certificates stored with a chain.

At the bottom of the inventory viewing dialog, click **Query Certificate**, after selecting the certificate to view, to open a new browser tab to the certificate search page with the search criteria specifying only the certificate you selected. The *Revoked* and *Expired* check boxes will automatically be included if either condition is true for that certificate.

Figure 241: View Inventoried Certificates for a Certificate Store

## Scheduling Inventory for a Certificate Store

Scheduling inventory for a certificate store allows Keyfactor Command to inspect the certificates inside a given store and add them to the Keyfactor Command database.

**Tip**: The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Certificate Stores > Read Certificate Stores > Schedule

Permissions for certificate stores can be set at either the global or certificate store container level. See *Container Permissions* in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

### To schedule inventory:

- 1. In the Management Portal, browse to Locations > Certificate Stores.
- 2. On the Certificate Stores page, select the Certificate Stores tab (the default when you first visit the page).

- 3. On the Certificate Stores tab, highlight the row(s) in the certificate store grid of the store(s) for which you want to schedule inventory and click **Schedule Inventory** at the top of the grid, or choose **Schedule Inventory** from the right-click menu. The right-click menu supports operations on only one store at a time.
- 4. In the Certificate Store Inventory Schedule dialog, select a schedule for the store(s). You can choose to run the inventory *Daily*, on an *Interval*, *Immediately*, *Exactly Once*, or set inventorying to *Off*.
  - If you select Daily, you can set the time of day when the inventory should begin every day.
  - If you select **Interval**, you can select a scan frequency of anywhere from every 1 minute to every 12 hours.
  - If you select **Immediate**, the inventory will run within a few minutes of saving the record and will run only once. After this, the inventory schedule will be cleared.
  - If you select **Exactly Once**, you can select a date and time at which to run the inventory job. After the job has run, the inventory schedule will be cleared.
  - · Select Off to disable the inventory job.

You have the option to not schedule inventory on a store-by-store basis and instead create containers and set inventory schedules that will apply to all the stores added to each container. See Certificate Store Containers on the next page for information on creating containers.

Figure 242: Schedule Inventory for a Certificate Store Location

# **Querying Certificates for a Certificate Store**

The **Query Certificate Store** option allows you to open a new browser tab with an instance of the Management Portal open to the certificate search page pre-populated with search criteria to locate the certificates found in that certificate store.

**Tip**: The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Certificate Stores > Modify Certificate Stores > Read

Permissions for certificates and certificate stores can be set at either the global or certificate collection and certificate store container level. You can use a mixture with, for example, global certificate permissions and container-level certificate store permissions. See

Certificate Permissions and Container Permissions in the Keyfactor Command Reference Guide for more information about global vs collection and container permissions.

To use the query certificate store option:

- 1. In the Management Portal, browse to *Locations > Certificate Stores*.
- 2. On the Certificate Stores page, select the Certificate Stores tab (the default when you first visit the page).
- 3. On the Certificate Stores tab, highlight the row in the certificate store grid of the store for which you want to query certificates and click **Query Certificate Store** at the top of the grid, or choose **Query Certificate Store** from the right-click menu.

#### **Certificate Store Containers**

Certificate store containers allow you to collect similar stores together to provide organization, allow for simplified bulk operations and control access.

### **Using the Containers Search Feature**

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an *is null* or *is not null* comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

Each query consists of three parts:

### **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

Name	CertStoreType
Complete or partial matches with the name of the certificate store container.  Schedule	The certificate store type of the container.
Whether the certificate store container has a schedule defined, true/false.	

## **Comparison Operator**

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Contains (-contains)
- Does not contain (-notcontains)
  - •
- Most date and integer fields support:
- Is equal to (-eq)
- Is not equal to (-ne)
- Is less than (-It)
- Is less than or equal to (-le)
- Is greater than (-gt)
  - Is greater than or equal to (-ge)
  - Is null (-eq NULL)

• Is null (-eq NULL)

• Is not null (-ne NULL)

• Is not null (-ne NULL)

Starts with (-startswith)Ends with (-endswith)

- Most Boolean (true/false) fields support:
- Is equal to (-eq)
- Is not equal to (-ne)

- Is null (-eq NULL)
- Is not null (-ne NULL)

# Comparison Value

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

- Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.
- Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

Figure 243: Certificate Store Container Search

The search results can be sorted by clicking on a column header in the results grid for most columns. Click the column header again to reverse the sort order. The grid columns can be arranged in any order desired by click-holding and dragging the header of the column you wish to move. The column widths may be adjusted by click-holding and dragging the line separating two column headers.

#### Advanced Searches

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

#### **Multiple Criteria**

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click **Insert** to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

## **Certificate Store Container Operations**

Certificate store container operations include creating or editing containers—including scheduling inventory for the container-and deleting containers.

## Adding or Modifying a Certificate Store Container

Tip: The following permissions (see Security Roles and Claims in the Keyfactor Command Reference Guide) are required to use this feature:

Certificate Stores > Modify Certificate Stores > Read

To add or edit a certificate store container:

- 1. In the Management Portal, browse to Locations > Certificate Stores.
- 2. On the Certificate Stores page, select the Containers tab.

Figure 244: Certificate Store Containers

- 3. On the Containers tab, click Add to create a new container, or click Edit from either the top or right-click menu to modify an existing one.
- 4. In the Schedule Container dialog, select the appropriate Type for the container from the dropdown. This field cannot be modified on an edit.

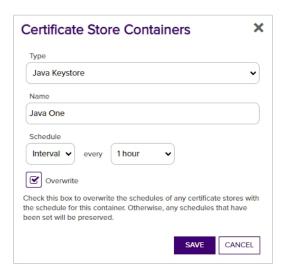

Figure 245: Define a Certificate Store Container

- 5. Enter a name for the container in the Name field.
- 6. In the **Inventory Schedule** fields, select an inventory frequency to apply as a default to certificate stores added to the container. The choices are:
  - · Daily at a selected time
  - At intervals of anywhere from every one minute to every 12 hours
  - Off
- 7. If desired, check the **Overwrite Existing Schedules** box. This option will apply the schedule from the container to any stores in the container, including those that already have a schedule, whenever the container schedule is updated.
- 8. Click Save to save the container.

# **Deleting a Container**

Deleting a container that contains certificate stores does not delete the associated certificate stores. The certificate stores will remain and be disassociated from the container.

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Certificate Stores > Modify

Certificate Stores > Read

To delete a certificate store container:

- 1. In the Management Portal, browse to Locations > Certificate Stores.
- 2. On the Certificate Stores page, select the Containers tab.

- 3. On the Containers tab, highlight the row in the certificate store containers grid of the container to delete and click **Delete** at the top of the grid or right-click the container in the grid and choose Delete from the right-click menu. Only one container may be deleted at a time.
- 4. On the Confirm Operation alert, click **OK** to confirm or **Cancel** to cancel the operation.

#### **Container Permissions**

Although permissions for a container can be viewed or modified using the permission option on the certificate store containers tab, Keyfactor recommends best practice is to manage permissions as part of the overall permission configuration on the Security Roles and Claims on page 623 page, as additional system-wide configuration settings are available there that cannot be viewed or modified from this page. For more information, see Container Permissions on page 630 and Security Roles and Claims on page 623.

## **Certificate Store Discovery**

The certificate store discovery feature is used to scan machines and devices for existing certificates and certificate stores, which can then be configured for management in Keyfactor Command. Certificate store discovery is supported for the following built-in certificate stores and Keyfactorprovided custom-built extensions on GitHub:

- · PEM and Java certificate stores discovered by the Keyfactor Java Agent. Only stores on which the service account running the Keyfactor Java Agent has at least read permissions will be returned on a discover job.
- F5 CA bundles and F5 SSL certificates discovered using the F5 Certificate Store Manager extension from Keyfactor GitHub and the Keyfactor Universal Orchestrator.
- Java Keystores, PKCS12 files, PEM files, DER files, and IBM Key Database files discovered using the Remote File Certificate Store Management extension from Keyfactor GitHub and the Keyfactor Universal Orchestrator.

The small number that appears on the tab to the right of the word Discover indicates how many discovered stores there are, if any. This acts as a reminder to check the discover tab for stores after a discovery job is complete.

## Scheduling a Certificate Store Discovery Job

Tip: The following permissions (see Security Roles and Claims in the Keyfactor Command Reference Guide) are required to use this feature:

Certificate Stores > Modify Certificate Stores > Read Certificate Stores > Schedule PAM > Read

To use the certificate store discovery feature:

- 1. In the Management Portal, browse to *Locations > Certificate Stores*.
- 2. On the Certificate Store page, select the Discover tab.
- 3. On the Discover tab, click Schedule.
- 4. In the Schedule Discovery dialog, select the type of certificate store job in the **Category** drop-down. The values that appear here are the display names for the built-in certificate store types and any custom certificate store types you entered to match your custom extensions.

Figure 246: Schedule Java Keystore Discover Job for Remote File Extension

Figure 247: Schedule F5 SSL Discover Job for F5 Extension

- 5. In the **Orchestrator** field, select the fully qualified domain name of the approved Keyfactor Universal Orchestrator managing the scanning. This field is required.
- 6. In the **Schedule** dropdown, select either *Immediate*, to run the discover job within a few minutes of saving it, or *Exactly Once*, to select a date and time for the job. The default is Immediate.
- 7. In the **Client Machine** field, enter the fully qualified domain name or IP address of the target server or device to be scanned.
- 8. Click **Set Server Username** and, in the Server Username dialog, choose the source from which to load a user valid on the target server or device with sufficient permissions to read the store locations and open files (for F5 this should be Administrator permissions). In the Server Username dialog, the options are Load From Keyfactor Secrets or Load From PAM Provider. The *No Value* option is typically not supported for remote file targets and F5 devices.

**Note**: Although a user with Resource Administrator permissions is sufficient when using the F5 methods that use the SOAP API, the F5 methods that use the REST API require full Administrator permissions.

A Keyfactor secret is a user-defined password or other information that is encrypted and stored securely in the Keyfactor Command database. Although Keyfactor recommends using Privileged Access Management (see <a href="Privileged Access Management">Privileged Access Management (PAM) on page 744</a>) as a more secure solution to secure information, Keyfactor Secret is an option for customers that do not already have a relationship with a PAM provider such as CyberArk or Delinea.

**Important:** Keyfactor highly recommends that you use strong passwords for any accounts or certificates related to Keyfactor Command and associated products, especially when these have elevated or administrative access. A strong password has at least 12 characters (more is better) and multiple character classes (lowercase letters, uppercase letters, numeral, and symbols). Ideally, each password would be randomly generated. Avoid password re-use.

Select the **Load From Keyfactor Secrets** radio button as the *Secret Source* if you want Keyfactor Command to encrypt and store the password in the Keyfactor Command database. Enter and confirm a password.

Select the **Load from PAM Provider** radio button as the *Secret Source* if you want to store the password in a supported third-party PAM solution (see <u>Privileged Access Management (PAM) on page 744</u>). The remaining fields on the dialog will vary depending on the PAM provider. For example:

## CyberArk

Select your CyberArk provider in the **Providers** dropdown if your PAM provider is CyberArk (see Adding or Modifying a PAM Provider on page 752). The remaining fields in the dialog will then be:

- Safe—The name of the safe the credential resides in.
- Object—The name of the username or password object in the safe.
- Folder—The path and name of the folder that stores the object (e.g. Root or Root\MyDir).

#### Delinea

Select your Delinea provider in the **Providers** dropdown if your PAM provider is Delinea (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining field in the dialog will then be:

- Secret Server Secret ID-The numeric ID of the secret to retrieve from Secret Server.
- Secret Field Name—The name of the field to use when retrieving a secret form Secret Server.

### Hashicorp

Select your Hashicorp Vault provider in the **Providers** dropdown if your PAM provider is Hashicorp Vault (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining field in the dialog will then be:

- KV Secret Key-The key of the secret to retrieve from the Hashicorp Vault.
- KV Secret Name—The name of the secret to retrieve from the Hashicorp Vault.
- 9. Click Set Server Password and, in the Server Password dialog, choose the source from which to load the password for the user specified with Set Server Username. In the Server Password dialog, the options are Load From Keyfactor Secrets or Load From PAM Provider. The No Value option is typically not supported for remote file targets and F5 devices.

A Keyfactor secret is a user-defined password or other information that is encrypted and stored securely in the Keyfactor Command database. Although Keyfactor recommends using Privileged Access Management (see <a href="Privileged Access Management (PAM)">Privileged Access Management (PAM)</a> on page 744) as a more secure solution to secure information, Keyfactor Secret is an option for customers that do not already have a relationship with a PAM provider such as CyberArk or Delinea.

**Important:** Keyfactor highly recommends that you use strong passwords for any accounts or certificates related to Keyfactor Command and associated products, especially when these have elevated or administrative access. A strong password has at least 12 characters (more is better) and multiple character classes (lowercase letters, uppercase letters, numeral, and symbols). Ideally, each password would be randomly generated. Avoid password re-use.

Select the **Load From Keyfactor Secrets** radio button as the *Secret Source* if you want Keyfactor Command to encrypt and store the password in the Keyfactor Command database. Enter and confirm a password.

Select the **Load from PAM Provider** radio button as the *Secret Source* if you want to store the password in a supported third-party PAM solution (see <u>Privileged Access Management (PAM) on page 744</u>). The remaining fields on the dialog will vary depending on the PAM provider. For example:

### CyberArk

Select your CyberArk provider in the **Providers** dropdown if your PAM provider is CyberArk (see Adding or Modifying a PAM Provider on page 752). The remaining fields in the dialog will then be:

- Safe—The name of the safe the credential resides in.
- Object—The name of the username or password object in the safe.
- Folder—The path and name of the folder that stores the object (e.g. Root or Root\MyDir).

### Delinea

Select your Delinea provider in the **Providers** dropdown if your PAM provider is Delinea (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining field in the dialog will then be:

- Secret Server Secret ID—The numeric ID of the secret to retrieve from Secret Server.
- Secret Field Name—The name of the field to use when retrieving a secret form Secret Server.

## Hashicorp

Select your Hashicorp Vault provider in the **Providers** dropdown if your PAM provider is Hashicorp Vault (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining field in the dialog will then be:

- KV Secret Key-The key of the secret to retrieve from the Hashicorp Vault.
- KV Secret Name—The name of the secret to retrieve from the Hashicorp Vault.
- 10. In the **Directories to search** field, specify the directory or directories to search. Multiple directories should be separated by commas. The data to enter here will vary depending on the certificate store(s) being discovered. For Keyfactor GitHub extensions, check the extension documentation for more information. This field is required.

### In general:

- Java, PEM, PKCS12, DER, IMB
   Enter at a minimum either "/" for a Linux server or "c:\" for a Windows server (without the quotation marks).
- F5
   Enter "/" (without the quotation marks). (This field is required but ignored by the discovery job for F5, so any value entered here will do.)
- 11. Populate the remaining optional fields as needed. See <u>Table 14: Discovery Options</u>.
- 12. Click **Save** to schedule the discovery task. Once the scan begins, it may take several minutes to complete.
- 13. Return to the Discover tab for the results of the scan. Check the Orchestrator Jobs page (see Orchestrator Job Status on page 511) to review jobs in progress.

## **Managing Discovered Certificate Stores**

**Tip**: The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Certificate Stores > Modify Certificate Stores > Read PAM > Read

To manage discovered certificate stores:

- 1. In the Management Portal, browse to *Locations > Certificate Stores*.
- 2. On the Certificate Stores page, select the Discover tab.

3. On the Discover tab, highlight one or more store row(s) in the grid and click **Manage** at the top of the grid or right-click the store in the grid and choose **Manage** from the right-click menu. Discovered certificate stores that require entry of either a server username and password or store password (or PAM credential access information) during the approval process must all share the same password or PAM information if you select more than one for approval at the same time. The right-click menu supports operations on only one store at a time. Certificate Stores <sup>9</sup>

Certificate stores exist on remote machines and contain certificates used by various applications. Certificate stores may be Java Keystores, PEM files, application-specific locations on remote devices or services such as AWS, or other formats.

Figure 248: Discovered Certificate Stores

4. The fields that appear on the Manage Certificate Stores dialog will vary depending on the certificate store type. If you're using a Keyfactor custom-built extension from GitHub, be sure to consult the documentation on GitHub for the specific extension. The following are some examples.

## Java Keystore with the Remote File Extension

- If desired, select a **Container** from the dropdown.
- Click the Set Password button to enter the password for the keystore. In the Password dialog, the options are No Value, Load From Keyfactor Secrets, and Load From PAM Provider.

Figure 249: Java Keystore Set Password

Select No Value if your keystore does not have a password configured.

A Keyfactor secret is a user-defined password or other information that is encrypted and stored securely in the Keyfactor Command database. Although Keyfactor recommends using Privileged Access Management (see <a href="Privileged Access Management (PAM)">Privileged Access Management (PAM)</a> on <a href="Page 744">Page 744</a>) as a more secure solution to secure information, Keyfactor Secret is an option for customers that do not already have a relationship with a PAM provider such as CyberArk or Delinea.

**Important:** Keyfactor highly recommends that you use strong passwords for any accounts or certificates related to Keyfactor Command and associated products, especially when these have elevated or administrative access. A strong password has at least 12 characters (more is better) and multiple character classes (lowercase letters, uppercase letters, numeral, and symbols). Ideally, each password would be randomly generated. Avoid password re-use.

Select the **Load From Keyfactor Secrets** radio button as the *Secret Source* if you want Keyfactor Command to encrypt and store the password in the Keyfactor Command database. Enter and confirm a password.

Select the **Load from PAM Provider** radio button as the *Secret Source* if you want to store the password in a supported third-party PAM solution (see <u>Privileged Access</u> <u>Management (PAM) on page 744</u>). The remaining fields on the dialog will vary depending on the PAM provider. For example:

## CyberArk

Select your CyberArk provider in the **Providers** dropdown if your PAM provider is CyberArk (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining fields in the dialog will then be:

- Safe—The name of the safe the credential resides in.
- Object—The name of the username or password object in the safe.
- Folder—The path and name of the folder that stores the object (e.g. Root or Root\MyDir).

### Delinea

Select your Delinea provider in the **Providers** dropdown if your PAM provider is Delinea (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining field in the dialog will then be:

- Secret Server Secret ID—The numeric ID of the secret to retrieve from Secret Server.
- Secret Field Name—The name of the field to use when retrieving a secret form Secret Server.

## Hashicorp

Select your Hashicorp Vault provider in the **Providers** dropdown if your PAM provider is Hashicorp Vault (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining field in the dialog will then be:

- KV Secret Key—The key of the secret to retrieve from the Hashicorp Vault.
- ° KV Secret Name—The name of the secret to retrieve from the Hashicorp Vault.
- The Linux File Permissions on Store Creation and Linux File Owner on Store Creation
  fields apply to the creation of new certificate stores on the target, and do not apply to
  discovered stores. These fields may be left blank.
- Click Set Server Username and, in the Server Username dialog, choose the source from
  which to load a user valid on the target server or device with sufficient permissions to
  read the store locations and open files (for F5 this should be Administrator permissions).
  In the Server Username dialog, the options are Load From Keyfactor Secrets or Load
  From PAM Provider. The No Value option is typically not supported for remote file targets.

**Note**: Although a user with Resource Administrator permissions is sufficient when using the F5 methods that use the SOAP API, the F5 methods that use the REST API require full Administrator permissions.

Click Set Server Password and, in the Server Password dialog, choose the source from
which to load the password for the user specified with Set Server Username. In the
Server Password dialog, the options are Load From Keyfactor Secrets or Load From
PAM Provider. The No Value option is typically not supported for remote file targets.

Figure 250: F5 SSL Profiles Set Password

A Keyfactor secret is a user-defined password or other information that is encrypted and stored securely in the Keyfactor Command database. Although Keyfactor recommends using Privileged Access Management (see <a href="Privileged Access Management (PAM)">Privileged Access Management (PAM)</a> on <a href="Page 744">Page 744</a>) as a more secure solution to secure information, Keyfactor Secret is an option for customers that do not already have a relationship with a PAM provider such as CyberArk or Delinea.

**Important:** Keyfactor highly recommends that you use strong passwords for any accounts or certificates related to Keyfactor Command and associated products, especially when these have elevated or administrative access. A strong password has at least 12 characters (more is better) and multiple character classes (lowercase letters, uppercase letters, numeral, and symbols). Ideally, each password would be randomly generated. Avoid password re-use.

Select the **Load From Keyfactor Secrets** radio button as the *Secret Source* if you want Keyfactor Command to encrypt and store the password in the Keyfactor Command database. Enter and confirm a password.

Select the **Load from PAM Provider** radio button as the *Secret Source* if you want to store the password in a supported third-party PAM solution (see <u>Privileged Access</u>

<u>Management (PAM) on page 744</u>). The remaining fields on the dialog will vary depending on the PAM provider. For example:

## CyberArk

Select your CyberArk provider in the **Providers** dropdown if your PAM provider is CyberArk (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining fields in the dialog will then be:

- ° Safe—The name of the safe the credential resides in.
- Object—The name of the username or password object in the safe.
- Folder—The path and name of the folder that stores the object (e.g. Root or Root\MyDir).

### Delinea

Select your Delinea provider in the **Providers** dropdown if your PAM provider is Delinea (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining field in the dialog will then be:

- Secret Server Secret ID—The numeric ID of the secret to retrieve from Secret Server.
- Secret Field Name—The name of the field to use when retrieving a secret form Secret Server.

## Hashicorp

Select your Hashicorp Vault provider in the **Providers** dropdown if your PAM provider is Hashicorp Vault (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining field in the dialog will then be:

- KV Secret Key—The key of the secret to retrieve from the Hashicorp Vault.
- KV Secret Name—The name of the secret to retrieve from the Hashicorp Vault.
- In the **Use SSL** section, select *True* to use SSL to communicate with the remote target, if desired. For more information, see <u>Table 14</u>: <u>Discovery Options</u>.

Figure 251: Manage a Discovered Java Certificate Store

#### F5 SSL Profile Certificate with the F5 Extension

- If desired, select a Container from the dropdown.
- In the **Primary Node** field, enter the fully qualified domain name of the F5 device that acts as the primary node in a highly available F5 implementation. If you're using a single F5 device, this will often be the same value you entered in the Client Machine field.

**Tip:** Configuration of the primary node is necessary to allow management jobs that update certificates on the F5 device to wait until the primary node is available before making their update. Inventory jobs are carried out against any available node.

 In the Primary Node Check Retry Wait Seconds field, either accept the default value of 120 seconds or enter a new value. This value represents the number of seconds the orchestrator will wait after a pending management job cannot be completed because the primary node cannot be contacted before trying to contact the primary node again to retry the job.

- In the Primary Node Check Retry Maximum field, either accept the default value of 3 retry
  attempts or enter a new value. This value represents the number of times the orchestrator will retry a pending management job that is failing because the primary node cannot
  be contacted before declaring the job failed.
- In the **Version of F5** dropdown, select the version of F5 this server is running. The F5 REST API is supported on version 13 and up.

**Tip:** Select v15 for version 15 and above.

Click Set Server Username to choose the source from which to load a user valid on the F5 device with Administrator permissions. In the Server Username dialog, the options are Load From Keyfactor Secrets or Load From PAM Provider. The No Value option is typically not supported for F5 stores.

**Note**: Although a user with Resource Administrator permissions is sufficient when using the F5 methods that use the SOAP API, the F5 methods that use the REST API require full Administrator permissions.

Click Set Server Password to choose the source to load a valid password for the server.
 In the Server Password dialog, the options are Load From Keyfactor Secrets or Load
 From PAM Provider. The No Value option is typically not supported for F5 stores.

Figure 252: F5 SSL Profiles Set Password

A Keyfactor secret is a user-defined password or other information that is encrypted and stored securely in the Keyfactor Command database. Although Keyfactor recommends using Privileged Access Management (see <a href="Privileged Access Management (PAM)">Privileged Access Management (PAM)</a> on <a href="page 744">page 744</a>) as a more secure solution to secure information, Keyfactor Secret is an option for customers that do not already have a relationship with a PAM provider such as CyberArk or Delinea.

**Important:** Keyfactor highly recommends that you use strong passwords for any accounts or certificates related to Keyfactor Command and associated products, especially when these have elevated or administrative access. A strong password has at least 12 characters (more is better) and multiple character classes (lowercase letters, uppercase letters, numeral, and symbols). Ideally, each password would be randomly generated. Avoid password re-use.

Select the **Load From Keyfactor Secrets** radio button as the *Secret Source* if you want Keyfactor Command to encrypt and store the password in the Keyfactor Command database. Enter and confirm a password.

Select the **Load from PAM Provider** radio button as the *Secret Source* if you want to store the password in a supported third-party PAM solution (see <u>Privileged Access</u> <u>Management (PAM) on page 744</u>). The remaining fields on the dialog will vary depending on the PAM provider. For example:

## CyberArk

Select your CyberArk provider in the **Providers** dropdown if your PAM provider is CyberArk (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining fields in the dialog will then be:

- ° Safe—The name of the safe the credential resides in.
- Object—The name of the username or password object in the safe.
- Folder—The path and name of the folder that stores the object (e.g. Root or Root\MyDir).

## Delinea

Select your Delinea provider in the **Providers** dropdown if your PAM provider is Delinea (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining field in the dialog will then be:

- Secret Server Secret ID—The numeric ID of the secret to retrieve from Secret Server.
- Secret Field Name—The name of the field to use when retrieving a secret form Secret Server.

## Hashicorp

Select your Hashicorp Vault provider in the **Providers** dropdown if your PAM provider is Hashicorp Vault (see <u>Adding or Modifying a PAM Provider on page 752</u>). The remaining field in the dialog will then be:

- ° KV Secret Key-The key of the secret to retrieve from the Hashicorp Vault.
- ° KV Secret Name—The name of the secret to retrieve from the Hashicorp Vault.
- In the **Use SSL** section, select *True* to use SSL to communicate with the F5 device or cluster, if desired. For more information, see <u>Table 14</u>: <u>Discovery Options</u>.

Figure 253: Manage a Discovered F5 SSL Profile Certificate

# **Deleting a Discovered Certificate Store**

Discovered certificate stores can be deleted one at a time or in multiples.

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

# Certificate Stores > Modify Certificate Stores > Read

To delete a discovered certificate store:

- 1. In the Management Portal, browse to *Locations > Certificate Stores*.
- 2. On the Certificate Stores page, select the Discover tab.
- 3. On the Discover tab, highlight the row(s) in the discover grid of the store(s) to delete and click **Delete** at the top of the grid or right-click the store location in the grid and choose **Delete** from the right-click menu. The right-click menu supports operations on only one store at a time.
- 4. On the Confirm Operation alert, click **OK** to confirm or **Cancel** to cancel the operation.

The following table includes only default fields for discovery jobs, not any custom fields specific to a certain certificate store type.

Table 14: Discovery Options

Option	Description
Category	Select the type of certificate store to scan.
Orchestrator	Select the fully qualified domain name of the Keyfactor Universal Orchestrator managing the scanning. This field is required.
Schedule	Specify the schedule for the scan—Immediate or Exactly Once. If you select Exactly Once, select a date and time for the scan. The default is Immediate.
Client Machine	Specify the fully qualified domain name or IP address of the remote target, device or cluster to be scanned for certificates. This field is required.
Server User- name	Set the username used to authenticate to the remote target, device or cluster.
Server Pass- word	Set the password used to authenticate to the remote target, device or cluster.
Directories to search	Specify the directory or directories to be searched. Multiple directories should be separated by commas. All directories specified to which the specified user (see <i>Server Username</i> ) has read rights will be searched other than the excluded directories specified using the <i>Directories to ignore</i> option. It is not necessary to use quotation marks around directory paths containing spaces. For F5, the path should be specified as "/" (without the quotation marks). This field is required.
Directories to ignore	Specify any directories that should not be included in the search. Multiple directories should be separated by commas. It is not necessary to use quotation marks around directory paths containing spaces.

Option	Description
Extensions	Specify file extensions for which to search. For example, search for files with the extension <i>jks</i> but not <i>txt</i> . The dot should not be included when specifying extensions. To include files without extensions, include <i>noext</i> in the extension list. For example:  jks, noext
File name patterns to match	Specify all or part of a string against which to compare the file names of certificate store files and return only those that contain the specified string. It is not necessary to use quotation marks around strings containing spaces.
Follow SymLinks	If this option is specified, the tool will follow symbolic links on Linux and UNIX operating systems and report both the actual location of a found certificate store file in addition to the symbolic link pointing to the file. This option is ignored for searches of Windows-based targets.
Include PKCS12 Files	If this option is specified, the tool will use the compatibility mode introduced in Java version 1.8 to locate both JKS and PKCS12 type files if supported by the extension. This option applies only to Java keystore discover jobs.
Use SSL	Use SSL to communicate to the remote target, device or cluster.  If the remote target is an F5 device and you're using the F5 extension, the device must trust the CA that issued the certificate used to protect the Keyfactor Command server or you must set the <i>Ignore Server SSL Warnings</i> application setting to <i>True</i> (see Application Settings on page 602).  If the remote target is a Windows server and you're using the Remote File or IIS extension, WinRM on the target must be configured to support HTTPS and have been configured with an SSL certificate (see <i>Configure Windows Targets for Remote Management</i> in the <i>Keyfactor Orchestrators Installation and Configuration Guide</i> ).

### 2.1.8.4 SSL Discovery

SSL network discovery and monitoring is used to survey designated internet-facing or internal IP addresses and ports to locate and import certificates, as well as alert certificate owners when the certificates are nearing expiration or are not found. Discovery jobs scan network segments to locate certificates at TLS endpoints; whereas, monitoring jobs inspect certificates for health and expiration and notify recipients regarding the status of the certificates. With the introduction of the Keyfactor Universal Orchestrator, SSL discovery can scan TLS 1.3 endpoints using any of the 5 ciphersuites referenced in appendix B.4 of RFC 8446.

SSL network discovery and monitoring scanning is performed by orchestrators that are assigned to orchestrator pools. An orchestrator pool contains orchestrators that support SSL discovery and monitoring capabilities for its networks. Orchestrator architecture allows for a pool of orchestrators to work in parallel to execute scan jobs. Based on defined schedules, Keyfactor Command creates discovery or monitoring scan jobs. Several scan jobs may be created from one large request. Orchestrators poll the Keyfactor Command Service to determine if scan jobs are available. Scan

jobs are then executed by available orchestrators. Keyfactor Command automatically distributes the scanning load across the orchestrators in the pool by generating and managing individual scan jobs. Additionally, the orchestrator that discovers the certificate can be different than the orchestrator that monitors the certificate.

The orchestrator SSL scanning process will attempt to scan with and without server name indication (SNI) for endpoints specified by host name during discovery scans and only use SNI during a monitoring scan if the endpoint has an SNI name from the discovery scan. Whenever an endpoint is defined to scan by its host name, the orchestrator will try to scan that endpoint twice, one normal scan against the endpoint and one using the supplied host name as the SNI extension.

Keyfactor Command is installed with a *Default Orchestrator Pool* that holds all the orchestrators that have been configured for SSL network discovery and monitoring. Custom orchestrator pools can be created as needed.

**Note**: The orchestrators in the network's orchestrator pool must have access to the network the pool is assigned to scan. Ideally, orchestrators are placed in close network proximity to the addresses they are configured to scan. Scanning across WAN or slow network links can impact performance and potentially miss certificates due to timeouts or network congestion. Additionally, firewalls between the orchestrators and their target networks need to be configured to allow connections to the scanned addresses and ports.

SSL network discovery and monitoring is divided into three areas:

#### Network Definitions

Network definitions are used to define a collection of networks that will be scanned by the designated orchestrator pool. Networks are defined using IP addresses, ports and hostnames. Within this option, you can schedule discovery and/or monitoring tasks. You can also configure networks to automatically tag a discovered endpoint with a certificate for monitoring.

# • Orchestrator Pools Definition

On the orchestrator pools definition tab you define a group of available orchestrators that support the SSL discovery and monitoring capabilities. For each orchestrator added to the orchestrator pool, you can select discover and/or monitor option(s).

### Results

The results tab shows the results of endpoints that have been scanned, including both positive (true, a certificate was found) or negative (false, a certificate was not found) results. If a response was received from an endpoint during a scan, it is included in the results; negative results are hidden by default. The *Monitor Status* (True/False) and *Reviewed Status* (True/False) of an endpoint are included in the results tab.

The SSL network discovery and monitoring features can only be used if at least one compatible (see Compatibility Matrix) instance of the Keyfactor Universal Orchestrator is running in the environment and the orchestrator has been approved in the Management Portal. Keyfactor recommends that the orchestrator(s) used for SSL network discovery and monitoring be installed on a server other than the primary Keyfactor Command server(s) due to the resource requirements of the scanning process when scanning large network segments.

Tip: Click the help icon (3) next to the page title to open the embedded web copy of the Keyfactor Command Documentation Suite to this section.

You can also find the help icon at the top of the page next to the Log Out button. From here you can choose to open either the Keyfactor Command Documentation Suite at the home page or the Keyfactor API Endpoint Utility.

### **Network Definitions**

On the Network Definitions tab you can create, edit and delete networks, and run and view scans. This section is also used to view the results of the discovery and monitoring jobs by linking directly to the Results tab for a selected network.

Discovery jobs attempt to initiate TLS connections to specified IP addresses and ports or ranges of IP addresses and ports. If a TLS connection is successful, the certificates provided by the target server as part of the TLS handshake are downloaded for further inspection and importation into the Keyfactor Command database. Locations that provide any level of response during the connection attempt (don't time out) are shown in the results grid when the discovery scan finishes regardless of whether a certificate was successfully downloaded. If a TCP connection is established, but a TLS connection is not, an SSL connection will be attempted. Any certificate obtained via SSL connection will be imported into the Keyfactor Command database. If a TLS connection is successful, an SSL connection will not be attempted.

Monitoring jobs scan a chosen set of locations that have already been discovered by a discovery job scan. Like discovery jobs, monitoring jobs attempt to initiate TLS connections with the locations specified. In the case of monitoring jobs, however, a certificate is expected at the endpoint since endpoints are generally identified for monitoring if they have certificates that need monitoring. As a result, monitoring jobs report on timeouts as well as connection failures and successes.

The network definitions grid includes these fields:

### Name

The name of the network.

### **Orchestrator Pool**

The name of the orchestrator pool (see Orchestrator Pools Definition on page 471).

### **Discovery Status**

The current status of the discovery job for the network, if configured. The possible statuses are:

- · Scheduled indicates a job has been scheduled but has never run.
- Last Scanned indicates a job has run to completion. The date indicates when the job finished.

### **Monitor Status**

The current status of the monitoring job for the network, if configured. The possible statuses are the same as those for discovery.

# Description

The description entered in the network definition.

- Running indicates a job is currently in progress.
   The percentage complete shown will be zero for small jobs for the entire duration of the job because this value is updated upon completion of each segment of a scan job (and small jobs generally consist of only one segment).
- In Quiet Hours indicates that a quiet hours time window for the job is currently in effect and no jobs can be run (see <u>SSL Network Operations</u> below).
- Disabled indicates that the Scanning Enabled box has been unchecked in the network definition (see <u>SSL Network Operations below</u>). No scanning jobs will be run when the network is in this state.

### **SSL Network Operations**

SSL Network Operations include adding, editing and deleting SSL network definitions, initiating a manual scan and monitoring scheduled network scan jobs.

**Tip:** SSL scan jobs use priority rules to determine which job segments run first if there are multiple job segments to be run (large jobs are divided into multiple job segments—see Monitoring Network Scan Jobs with View Scan Details on page 466). Job segments are run with the following priority rules:

- Job segments for Scan Now jobs (see <u>Initiating a Manual Scan on page 467</u>) are run ahead of those for scheduled jobs.
- New job segments for in-progress jobs with multiple segments are prioritized based on job age—segments for jobs that have been running the longest move to the front of the line.
- New job segments for in progress jobs with multiple segments start ahead of job segments for jobs that have not yet started.

# SSL Discovery • Keyfactor can be configured to scan SSL endpoints within your organization to discover certificates that you might wish to monitor and synchronize. Configure and run these scans below

Figure 254: SSL Network Discovery

# Adding or Modifying an SSL Network

To define a new network or edit an existing one:

- 1. In the Management Portal, browse to Locations > SSL Discovery.
- 2. On the SSL Network Discovery page, select the Network Definitions tab (the default when you first visit the page).
- 3. On the Network Definitions tab, click **New Network** to setup a network to scan, or select an existing network from the grid and click **Edit**.
- 4. The SSL Network Definition dialog is divided into four tabs: Basic, Advanced, Network Ranges, and Quiet Hours. Enter the network information for each tab, as required. Each tab is described in detail below.

### **Basic Tab**

In the SSL Network Definition dialog on the Basic tab, enter the following information:

Name: Enter a name for the network. The network name can be anything; however, it is
recommended that the name reflect the subnet or location that you will be discovering
with the network.

**Tip:** The SSL network name is searchable with certificate search and also appears in the location details grid of the certificate details, if the certificate was found during an SSL scan.

- Description: Enter a description for the network.
- Orchestrator Pool: From the dropdown, select an orchestrator pool that contains orchestrators with SSL discovery and monitoring capabilities.

**Note**: Keyfactor Command is installed with a Default Orchestrator Pool and orchestrators with SSL discovery and monitoring capabilities created in Keyfactor Command are automatically assigned to that pool.

- **Discovery/Monitoring Schedule**: Select the discovery and monitoring job frequency. Possible options are:
  - ∘ Off—No jobs will run.
  - Daily—Enter selected time.
  - o Interval—Enter an interval from every 10 minutes to every 12 hours.
  - Weekly—Enter a selected day or days of the week at a selected time.
  - ° Monthly—Enter a selected day of the month (1st through 27th) at a selected time.

**Note**: The configured schedule determines when the scan is requested to start. The actual start of the scan is dependent on the orchestrator heartbeat Interval, which is defined by the *Heartbeat Interval (minutes)* application setting (see <a href="Application Settings">Application Settings</a> on page 602). The default is 5 minutes.

• **Notification Recipients**: Enter one or more email address(es) of the recipients who should receive monitoring results (newline separated).

Figure 255: Define a New Network—Basic Tab

### **Advanced Tab**

In the SSL Network Definition dialog on the Advanced tab, enter the following information:

Scanning Enabled: Click to enable scanning for the network. If unchecked, no new
network scans will be scheduled, but the current scan will finish, if this setting is changed
during a scan also, the network will appear as *Disabled* on the SSL Network Discovery
page.

- Automatically monitor network endpoints during discovery: Enable this option to instruct the orchestrator to tag endpoint certificates, found during discovery scanning, for monitoring. It is recommended to enable this option.
- Request robots.txt: Each network definition contains an option to do a GET on robots.txt
   on endpoints. Orchestrators perform a GET /robots.txt request to behave like a
   webcrawler and provide an explanation of network activity.
- **Discover Timeout (in ms)**: Enter the amount of time (in milliseconds) the scan will wait (before timing out) to discover the endpoint. Shorter timeout periods will increase the overall scanning throughput, however will also increase the chance of missing a certificate on a slow or congested network
- Monitor Timeout (in ms): Enter the amount of time (in milliseconds) the scan will wait (before timing out) to receive the discovered endpoint certificate expiration details.
- Expiration Alert (in days): Enter the number of days within which to begin warning regarding upcoming expiration in notification email messages.

Figure 256: Define a New Network—Advanced Tab

### **Network Ranges Tab**

There are two sections to the Network Ranges Tab: **Add Range** and **Ranges**. For each named network defined, multiple ranges are allowed. New networks can be added by using either the *add range tool*, or pasting the IP address, hostname, or network notation into the Network Ranges box.

### The Add Range section

The **Add Range** section is for adding new networks via the *add range tool*. When you open the Network Ranges tab, the **Add Range** section shows default values of:

• Type: Network Notation

CIDR Block: 0.0.0.0/24:443

Notice that the details grid reflects the default value and the default type—network notation. As you begin entry of a new network range of the type network notation, the details section

will reflect your entries as you type, allowing you to verify your entry. The details grid will not show if you chose another type of notation.

Define new network locations, using the add range tool, as follows:

- a. In the **Add Range** section of the page, select your desired method for adding a location in the **Type** dropdown. The available options are:
  - Network Notation: Enter an IP address range using CIDR notation by populating the CIDR Block field and selecting the desired subnet in the dropdown. The default subnet is /24, which is one full octet of variability, or 254 locations.
  - IP Address: Enter a single IP address by populating the IP Address field and adding one port.
  - Host Name: Add a single location using a host machine name by filling in the Host
    Name field in the host name section and adding one port. During scans, host names
    are converted to IP addresses and scans are conducted via IP address. Keyfactor
    Command will do two scans against that address, one using the hostname as the SNI
    (server name indication) and one not using SNI. This is because different servers
    can be hosted on the same IP address but are accessed via different SNIs (or
    without one at all).

**Note:** All methods support adding multiple ports, either comma separated (433,450), or as a range (433-450).

- b. Enter the desired network notation, IP address, or host name, and click the **Add** action button.
- c. Repeat this step for multiple IP addresses or host names. Each entry will be added as a newline in the Network Ranges box at the bottom of the dialog.
- d. Click Save.

Figure 257: Define a New Network—Network Ranges Tab

The details grid displays only for the type *network notation* and will only display the value being typed in the CIDR block, or the last value entered. The fields in the details grid are defined as follows:

- Range: This is the range of addresses reflected by the CIDR notation entered.
- Mask: Defined by the bitmask (between 1-30) applied to the address in the CIDR block
  to identify the IP addresses included. The bigger the mask the fewer IP addresses will
  fall under the defined range. For example, with a "/24", the first 3 sections of the IP
  address must match exactly, while the last section can be any value from 0 to 255.
- **Hosts**: This is the number of useable IP addresses in a given CIDR. (This is always two less than the number of endpoints. This is because the smallest address is reserved as

the address of the overall network the CIDR represents, while the largest is used as the broadcast address).

- Ports: This is the number of ports the given CIDR will have.
- Endpoints: The endpoints number reflects the number of endpoints based on the network size (/24, /25, etc) times the number of ports defined. Each time you go up in network size the network number will double ("/24" has 256, "/23" has 512, "/22" has 1,024 etc). So if you have just one port defined, the number of endpoints will be 256 for a "/24" network, but if you had 3 ports (like say 443-445) that number would jump to 768. The same scenario for a "/23" network would be 512 for one port and 1,536 for three ports.

### The Ranges section

You can see any existing network definitions in the Network Ranges box in the **Ranges** section of the dialog. The **Ranges** section:

- Displays existing defined network ranges.
- Allows you to edit or delete existing network ranges. To delete a network range, highlight the selected range and click **Delete** on your keyboard. To edit a network range, highlight the selection to change and type over with the desired value(s).
- Accepts typed or pasted ranges, bypassing the add range tool. To add a network range, click inside the network ranges text box and type the desired value(s) or paste from your local clipboard. Ranges added this way must also contain the ports notation (e.g, :443).
- Validates network ranges as defined. To validate the list of ranges defined for the
  network, click the Validate action button. Based on the result, either a green Network
  ranges are valid message will display, or an alert will pop up with the list of invalid
  ranges.

### **Ouiet Hours Tab**

Quiet hours are ranges of hours or days during which scanning will not take place. Any scans in progress when the quiet hour window is reached will pause for the duration of the window and resume when the window is complete. SSL scans will show a status of **In Quiet Hours** if scanning is currently in that status.

In the SSL Network Definition dialog on the Quiet Hours tab, define quiet hour periods as follows:

- a. In the Add Quiet Hours section of the page, select a day and time to begin a quiet hour period in the *Start* section.
- b. Select a day of the week and time to end the quiet hour period in the End section.

- c. Click Add to add the quiet hour period to the Quiet Hours section of the page.
- d. Repeat the above steps for any additional quiet hour periods.

**Note**: Quiet hours replace and expand upon the blackout period option that existed in previous versions of Keyfactor Command.

Figure 258: Define a New Network—Quiet Hours Tab

5. Click Save to save the new network definition or changes.

# **Deleting an SSL Network**

- 1. In the Management Portal, browse to *Locations > SSL Discovery*.
- 2. On the SSL Network Discovery page, select the Network Definitions tab (the default when you first visit the page).

- 3. On the Network Definitions tab, highlight the row in the SSL network grid of the network to delete and click **Delete** at the top of the grid or right-click the network in the grid and choose **Delete** from the right-click menu.
- 4. On the Confirm Operation alert, click **OK** to confirm or **Cancel** to cancel the operation.

# Monitoring Network Scan Jobs with View Scan Details

At any time, you can view the status of the latest scan jobs by viewing scan details from the *SSL Discovery* page. Right-click the network location in the grid and choose **View Scan Details** from the right-click menu or highlight the row in the network grid and click **View Scan Details** at the top of the grid.

This takes you to a separate page with separate tabs for Discovery and Monitoring jobs (see Figure 259: SSL Network Scan Details Page). Details for the last scanned job display above the grid in each tab and the scanned segments for the latest scan populate the grid. You will only see more than one row in the grid if the SSL management job was broken into segments due to having a large number of endpoints. The number of endpoints per segment is configurable (see the SSL Maximum Scan Job Size setting in Application Settings: Agents Tab on page 615). The grid will display the latest completed job and will be refreshed with new scan details when the next scan begins.

Figure 259: SSL Network Scan Details Page

To view details for a segment, double-click the segment, right-click the segment and choose **Details** from the right-click menu, or highlight the row in the scan details grid and click **Details** at the top of the grid (see SSL Network Scan Detail Segment Details on the next page).

Figure 260: SSL Network Scan Detail Segment Details

**Tip:** If jobs are taking longer to complete than expected, see <u>Slow SSL Jobs on page 828</u>.

### **Initiating a Manual Scan**

In addition to SSL scanning jobs that can be run as scheduled, the Network Definitions tab includes a feature that allows you to manually initiate a scan for a configured network at any time that a scan is not already running for the network or the network is not in quiet hours. When you initiate a scan using the scan now feature, you can choose whether to run a discovery scan, a monitoring scan, or both.

To initiate a manual scan for a network:

- 1. In the Management Portal, browse to *Locations > SSL Discovery*.
- 2. On the SSL Network Discovery page, select the Network Definitions tab (the default when you first visit the page).
- 3. On the Network Definitions tab, highlight the row in the SSL network grid of the network to scan and click **Scan Now** at the top of the grid or right-click the network in the grid and choose **Scan Now** from the right-click menu. The scan will begin immediately.

**Tip:** If a scan is already in progress for the network, the option to start a scan of that type will be grayed out and cannot be selected.

Figure 261: SSL Network ScanNow

### **Reset Scan**

Resetting an SSL scan deletes all scan jobs, scan job parts, logical scan jobs, and current schedules associated with the selected network. The agent job status relating to the SSL scans is set to failed and completed, and the agent is forced to register for a new session. Afterward, *Scan Now* is enabled to allow you to initiate a manual scan. When you select *Reset Scan*, you will receive a **Confirm Operation** message. Click **OK** to proceed or **Cancel** to quit.

**Tip:** If you have an SSL scan job that appears stuck or crashed without a failure result, you can use the reset scan option to cancel the dysfunctional scan job.

# **View Network Endpoints and View Discovered Endpoints**

See the Results on page 473 documentation for more information on these action buttons.

### Using the Network Scan Details Search

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an *is null* or *is not null* comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

Each query consists of three parts:

### **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

#### Agent

Complete or partial matches with the orchestrator name as listed in the Orchestrator field.

#### **Status**

Status matches or doesn't match the selected category—Not Started, In Progress, Complete The SSL scan will show a status of *In Quiet Hours* if scanning is currently in that status. See <u>SSL</u> Network Operations on page 457.

#### Start Time

The time at which scanning of the segment began. Supports the %TODAY% token (see Advanced Searches on the next page).

#### **EndTime**

The time at which scanning of the segment began. Supports the %TODAY% token (see Advanced Searches on the next page).

#### **EndpointCount**

The number of endpoints scanned in the segment. The maximum number of endpoints per segment is configurable (see the SSL Maximum Scan Job Size setting in Application Settings: Agents Tab on page 615).

# **Comparison Operator**

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

- Is equal to (-eq)
- Is not equal to (-ne)
- · Contains (-contains)
- Does not contain (-notcontains)
- Most date and integer fields support:
- Is equal to (-eq)
- Is not equal to (-ne)
- Is less than (-lt)
- Is less than or equal to (-le)
- Most Boolean (true/false) fields support:
- Is equal to (-eq)
- Is not equal to (-ne)

- Starts with (-startswith)
- Ends with (-endswith)
- Is null (-eq NULL)
- Is not null (-ne NULL)
- Is greater than (-gt)
- Is greater than or equal to (-ge)
- Is null (-eq NULL)
- Is not null (-ne NULL)
- Is null (-eq NULL)
- Is not null (-ne NULL)

# **Comparison Value**

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

- Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.
- Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

### **Advanced Searches**

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

### **Multiple Criteria**

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click **Insert** to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

In addition to the options available in the query builder, three special values can be used in selected searches by typing them in directly:

- %TODAY%
   Use the TODAY special value in place of a specific date in date queries. This option supports math operations, so you can use TODAY-10 or TODAY+30. The built-in *Certificates Expiring in 7 Days* collection uses this special value (see Certificate Collection Manager on page 85).
- %ME%
  Use the ME special value in place of a specific domain\user name in queries that match a

domain\user name. The built-in *My Certificates* collection uses this special value (see <u>Certificates</u> Collection Manager on page 85).

• %ME-AN%

Use the ME-AN special value in place of a specific user name excluding the domain. This is beneficial in environments with multiple domains where there is a desire to query for a user's certificates even if they were requested across multiple domains.

**Important**: The special query options of %TODAY%, %ME%, and %ME-AN% are only supported in uppercase. Lowercase equivalents (e.g. %me%) cannot be substituted.

### **Orchestrator Pools Definition**

SSL network discovery and monitoring scanning is performed by assigning an orchestrator pool, containing orchestrators with discovery and monitoring capabilities, to a network. An orchestrator pool contains one to many orchestrators that support the SSL discovery and monitoring capabilities. Network scanning using orchestrator pools allows the work to be dispersed among the orchestrators in the pool.

Out of the box, all approved Windows orchestrators and Keyfactor Universal Orchestrators with the SSL capability are assigned to a default orchestrator pool. For scanning of larger and more complicated networks, orchestrator pools can be configured with multiple orchestrators running concurrently to perform the scanning operation.

**Note**: Approved orchestrators assigned to a custom pool will be removed from the default orchestrator pool. If a custom pool is removed, the orchestrator will be re-assigned to the default orchestrator pool.

# SSL Discovery 9

Keyfactor can be configured to scan SSL endpoints within your organization to discover certificates that you might wish to monitor and synchronize. Configure and run these scans below

Network Definitions Orchestrator Pools Definition	Results			
ADD EDIT DELETE			Total: 2	REFRESH
Pool Name	Discover Orchestrators	Monitor Orchestrators		
Default Agent Pool	0	0		
SouthWest Orchestrator Pool	1	1		

Figure 262: SSL Orchestrator Pools

### **Orchestrator Pool Operations**

Orchestrator pool operations include: creating, editing or deleting pools.

# Adding or Modifying an Orchestrator Pool

- 1. In the Management Portal, browse to Locations > SSL Discovery.
- 2. On the SSL Network Discovery page, select the Orchestrator Pools Definition tab.
- 3. On the Orchestrator Pools Definition tab, click **Add** from the top menu to create a new pool, or **Edit** from either the top or right click menu, to modify an existing one.

**Note:** The available edit options include edit the name of the pool or select/de-select the discover/monitor options.

4. In the SSL Orchestrator Pool Definition dialog, enter a unique Orchestrator Pool name in the **Name** field.

Figure 263: Add an Orchestrator Pool

5. From the **Orchestrators** dropdown, select eligible orchestrators—those orchestrators that support monitor and discovery capabilities—to add to the orchestrator pool and click **Add**.

**Tip:** Orchestrators are added with discover and monitor responsibilities. You can deselect one of these options, if needed.

6. Highlight a row and click **Remove** to remove the orchestrator from the orchestrator pool. The orchestrator will be returned to the default orchestrator pool.

**Note**: You are not able to remove orchestrators from the default orchestrator pool; they are automatically removed if assigned to a custom orchestrator pool.

7. Click **Save** to save the orchestrator pool.

# **Deleting an Orchestrator Pool**

You may delete one expiration record at a time.

- 1. In the Management Portal, browse to Locations > SSL Discovery.
- 2. On the SSL Network Discovery page, select the **Orchestrator Pools Definition** tab and select the row you wish to delete.
- 3. Click **Delete** at the top of the grid, or from the right click menu.
- 4. On the Confirm Operation alert, click **OK** to confirm or **Cancel** to cancel the operation.

Note: You are not able to remove the default orchestrator pool.

### Results

The SSL network discovery and monitoring results include endpoints that returned certificates as well as endpoints that resulted in some level of response (did not time out) but did not return certificates.

Figure 264: SSL Discovery Results

For each endpoint discovered during the scan, the results grid includes the following:

### **DNS Name**

The host name converted to an IP address, or the IP address scanned. The DNS name is resolved by the orchestrator performing the scan, based on the DNS settings of the server running the orchestrator.

### SNI

The server name indication (SNI), if one is found.

### **IP Address**

The IP address scanned.

### **Port**

The port scanned.

### **Certificate Found**

Whether a certificate was found at the endpoint on the most recent scan (true/false).

### **Certificate CN**

Common name discovered on the certificate.

### **Orchestrator Pool**

The orchestrator pool name that contains the orchestrator that discovered and/or monitored the endpoint.

### **Network**

The name of the network.

### Monitored

Whether the discovered endpoint is configured for monitoring (true/false). If the *Automatically monitor endpoints found during discovery* option is enabled in the network definition, the orchestrator will, upon initial discovery, monitor the discovered certificate. You can change the monitoring status of a discovered endpoint in the results grid.

### Reviewed

The discovered endpoint has been reviewed (true/false). To denote an endpoint as reviewed, highlight the row in the results grid and click **Mark as Reviewed** at the top of the grid or right-click the endpoint and choose **Mark as Reviewed**.

# Using the Discovery Results Search Feature

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an *is null* or *is not null* comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

Each query consists of three parts:

# **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

AgentPoolName	NetworkName
Complete or partial matches with the orchestrator pool that contains orchestrators used to discover and monitor the results.	Complete or partial matches with the network name.
	Port
CertificateCN	Numeric matches with the port number for the
Complete or partial matches with the certificate common name.	discovered endpoint.

#### CertificateFound

Certificate was found at the endpoint on the most recent scan (true/false).

#### ReverseDNS

Complete or partial matches with the DNS name resolved based on the discovered IP address. If a host name could not be resolved, this will be the IP address.

### **IPAddress**

Complete or partial matches with the IP address.

#### IsMonitored

Endpoint has been marked as monitored (true/-false). By default, only endpoints that are marked as monitored equals true are displayed.

#### Issuer DN

Complete or partial matches with the issuer distinguished name.

#### Reviewed

Whether it is true or false that the scan has been reviewed.

#### SelfSigned

Certificate is self-signed (true/false).

### SNIName

The server name indication (SNI) of the endpoint.

#### **Status**

The status of the scan. Options include:

- · Certificate Found
- Timed Out Connecting
- · Exception Connecting
- Timed Out Downloading
- · Exception Downloading
- Not SSL
- · Exception in Sql
- · Invalid or Unreachable Host
- · Connection Refused
- Bad SSL Handshake
- · Client Authentication Failed
- · No Certificate
- · SSL Refused
- Not Probed
- Unknown

# **Comparison Operator**

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Contains (-contains)
- Does not contain (-notcontains)

- Starts with (-startswith)
- Ends with (-endswith)
- Is null (-eq NULL)
- Is not null (-ne NULL)

Most date and integer fields support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Is less than (-It)
- Is less than or equal to (-le)

- Is greater than (-gt)
- Is greater than or equal to (-ge)
- Is null (-eq NULL)
- Is not null (-ne NULL)

Most Boolean (true/false) fields support:

- Is equal to (-eq)
- Is not equal to (-ne)

- Is null (-eq NULL)
- Is not null (-ne NULL)

# **Comparison Value**

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

- Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.
- Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

### **Advanced Searches**

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

# **Multiple Criteria**

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click **Insert** to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template

referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

### **SSL Results Action Options**

The following options are available on the results tab:

- To view the details for a discovered endpoint, double-click the result, right-click the result and choose View Endpoint Details from the right-click menu, or highlight the row in the results grid and click View Endpoint Details at the top of the grid (see Viewing Endpoint Details below).
- To add a discovered endpoint to a monitoring job, right-click the result and choose **Monitor** from the right-click menu, or highlight the row in the results grid and click **Monitor** at the top of the grid.
- To remove an endpoint from a monitoring job, right-click a result that has a Monitor Status of *true* and choose **Do Not Monitor** from the right-click menu, or highlight the row in the results grid and click **Do Not Monitor** at the top of the grid.
- To change endpoints to reviewed, right-click the result and choose **Mark as Reviewed** from the right-click menu, or highlight the row in the results grid and click **Mark as Reviewed** at the top of the grid. Newly found endpoints default to a reviewed state of *false*.
- To change reviewed endpoints to not reviewed, right-click the result and choose **Mark as New** from the right-click menu, or highlight the row in the results grid and click **Mark as New** at the top of the grid.
- To add all discovered endpoints to a monitoring job, click Monitor All at the top of the grid.
- To change all endpoints to reviewed, click Mark All as Reviewed at the top of the grid.
- You can click the **Include Endpoints without Certificates** button at the top of the results grid to toggle inclusion of endpoints without certificates in the results. By default they are excluded.

To select a single row in the grid, click to highlight it and then select an operation from either the top of the grid or the right-click menu. Some of the operations support action on multiple results at once. To select multiple rows, hold down the CTRL key and click each row on which you would like to perform an operation. Then select an operation from the top of the grid. The right-click menu supports operations on only one certificate at a time.

### **Viewing Endpoint Details**

To view details of the scan history and certificates found for an SSL job, in the SSL discovery results grid, double-click the result, right-click the result and choose **View Endpoint Details** from the right-click menu, or highlight the row in the results grid and click **View Endpoint Details** at the top of the grid. The endpoint history dialog includes this information:

• The **SSL/TLS Endpoint Details** section of the dialog includes details of the selected certificate including the IP address, port, DNS name, SNI (if available), endpoint network name, orchestrator pool name that contained the orchestrator which performed the scan, and monitoring status of the certificate (true/false).

- The **Chain Level** dropdown allows you to view details of certificates chained to the selected certificate. The default is the end entity certificate.
- The Certificate Details section provides details of the certificate selected in the chain level dropdown.
- The Endpoint History section on the right side of the endpoint history dialog details each individual scan including the date of the scan, source (monitoring or discovery), the IP address and the certificate status.

The details menu can also provide information on why a certificate was not found if one was expected.

Endpoint history records on the endpoint details page older than 30 days, by default, are automatically purged daily. You can change the length of time for which records are retained by updating the *Retain SSL Endpoint History (days)* in the application settings.

Figure 265: SSL Discovery and Monitoring Result Details

### Tracking the Expiration on SSL Certificates

At the conclusion of a of a network monitoring scan, an email is sent to the configured recipients indicating which, if any, certificates associated with that network are nearing expiration. *Near* expir-

ation is determined based on the *Expiration Alert (in days)* setting in the network definition, which defaults to 7 days (see SSL Network Operations on page 457).

This is one method of tracking expiration on SSL certificates, but since the certificates are synchronized to the Keyfactor Command database, you can also use regular expiration alerts (see <a href="Expiration">Expiration</a> Alerts on page 167) and reports (see <a href="Reports on page 91">Reports on page 91</a>) to track expiration for these certificates as you would for certificates issued from internal CAs.

### **Understanding Notification Emails**

The discovery and monitoring notification emails that are delivered at the conclusion of discovery and monitoring scans both include information about the status of the endpoints scanned, but they present this information slightly differently. The discovery email breaks down what happened when the job attempted to find a certificate at each of the endpoints it attempted to communicate with. The monitoring email, on the other hand, focuses on monitoring the status of the certificate that is expected to be at the endpoint. Although the monitoring email can be used for identifying certificates that are coming up for expiration, other solutions, such as expiration alerts (see <a href="Expiration Alerts on page 167">Expiration</a>. May be more useful for this. What the expiration alerts can't do for you, however, and the monitoring email can, is identify servers that may have gone offline or whose certificate may have disappeared. In other words, expiration alerts monitor certificate status and monitoring alerts monitor endpoint status. See the example in <a href="Figure 267">Figure 267</a>: SSL Monitoring Email. This shows three servers that previously had been discovered to have a certificate now being unresponsive. In some cases, the servers or certificates may still be there and the requests for them have just timed out due to slow network connections or other issues, but this provides you with an opportunity to investigate these servers to determine what the problem might be.

The various numbers that are reported in the Discovery and Monitoring emails are:

- The number in the subject: The total number of endpoints that have expired/expiring certificates plus the total number of endpoints that did not return a certificate.
- Expired/Expiring certificates number: The total number of certificates that are expired or will expire within the next X number of days. The value of X is a configurable setting in Keyfactor Command and is set in the network definition for each network (see the Expiration Alert setting in SSL Network Operations on page 457).
- Number of endpoints that did not return a certificate: The total number of endpoints that did not return a certificate.
- Number of rows in each grid: A configurable setting in Keyfactor Command (see the SSL Maximum Email Results application setting in Application Settings: Agents Tab on page 615). The number of rows in the grids is not reflected in the total counts.

Keyfactor <keyfactor@keyexample.com>

± staf

SSL Discovery Scan for Network 'External Addresses' Has Completed

The SSL Discovery scan for network 'External Addresses' has completed.

The scan tested 3,048 endpoint(s) and generated the following probe statistics:

- · 44 endpoints served up a certificate
- 2,995 endpoints timed out while attempting a connection
- 0 endpoint probes timed out while attempting to download a certificate
- · 9 endpoint probes refused connections
- 8 endpoint probes did not support SSL, despite accepting a connection
- 0 endpoint probes refused SSL, despite accepting a connection
- · 0 endpoint probes started SSL but did not provide a certificate
- 1 endpoint probes experienced some other error

Note that multiple probes may be performed on an endpoint. Probe statistics totals may not equal the number of endpoints tested.

Figure 266: SSL Discovery Email

Keyfactor < keyfactor@keyexample.com>

SSL Monitoring Scan for Network 'External Addresses' Has Completed (6 endpoints require attention)

The SSL Monitoring scan for network 'External Addresses' has completed successfully.

The scan tested 39 endpoint(s) and found 36 endpoint(s) containing a certificate.

The scan found 3 endpoint(s) that were within 7 days of expiration or have expired:

<b>Expiration Date</b>	Subject	DNS Name	IP Address	Port
3/31/2020	appsrvr76.keyexample.com	srv39.west.int	10.4.3.183	443
4/22/2020	appsrvr77.keyexample.com	10.4.3.76	10.4.3.76	443
4/23/2020	appsrvr78.keyexample.com	10.4.3.245	10.4.3.245	443

The scan found 3 endpoint(s) that did not return a certificate:

DNS Name	IP Address	Port	Expiration Date
10.4.3.1	10.4.3.1	22	Not SSL
appsr6.keyexample.com	10.4.3.37	8443	Connection Timeout
webs7.keyexample.com	10.4.3.88	443	Connection Refused

Figure 267: SSL Monitoring Email

Table 15: SSL Email Notification Values Defined

Value	Meaning
Timed out while	A timeout occurred when attempting to establish a TCP connection. The timeout

Value	Meaning
connecting	interval is defined on the Advanced tab of the SSL network definition page, see <u>SSL Network Operations on page 457</u> . The shorter the timeout, the faster the scan goes, but the higher chance that if there is actually something listening at the port, a connection won't be established causing a timeout. If the orchestrator is overloaded (too many parallel tasks), it can add to the time needed to make a connection and increase the chance of a timeout. Network transit time affects timeouts as does the load and speed of the target system in the ability to establish a TCP handshake.
Timed out while downloading	A TCP connection was made and a TLS connection was started, but it took too long to actually receive the certificate. This is a rare condition. This is a parameter that is locally configurable on the orchestrator and defaults to 15 seconds. This value is displayed in the debug trace.
Connection refused	The target IP and Port are listening, but the TCP connection was actively refused.
Not SSL	A TCP connection was established, but when the first packet of the TLS handshake was sent, it did not get a TLS response, implying that some protocol other than TLS is listening on the target.
Bad SSL hand- shake	A TCP connection was established and a proper response to the first TLS packet was returned, but something failed in the rest of the TLS handshake. Several of the internal reasons for why a TLS handshake may have failed have been combined along with other counters in the email response.
Certificate found	A TCP connection and a TLS handshake were completed and the TLS handshake returned a certificate (all within the connection and download timeout periods)

# 2.1.9 Orchestrators

Keyfactor Command uses orchestrators (a.k.a. agents) to manage a wide variety of certificate store types. As of this writing, Keyfactor offers these orchestrators:

# **Keyfactor Universal Orchestrator**

This orchestrator runs on Windows servers or Linux servers and is used to run jobs at the request of the Keyfactor Command server. Jobs primarily perform certificate management tasks, but other types of operations are also supported. Jobs are provided to the orchestrator as extensions; both built-in and custom extensions are supported. The orchestrator includes built-in extensions to run SSL discovery and management tasks, manage synchronization of certificate authorities in remote forests, and retrieve the orchestrator logs for analysis with the Keyfactor API.

# **Keyfactor Java Agent**

This orchestrator runs on Windows or Linux servers and is used to perform discovery of Java keystores and PEM certificate stores, to inventory discovered stores, and to push certificates out to stores as needed.

**Important:** The Keyfactor Java Agent will be deprecated in a future version of Keyfactor Command. Customers are encouraged to begin planning a migration to the Keyfactor Universal Orchestrator with the Remote File custom extension publicly available at:

https://github.com/Keyfactor/remote-file-orchestrator

For more information, see Installing Custom-Built Extensions.

# **Keyfactor Mac Auto-Enrollment Agent**

This orchestrator runs on Apple Macintosh computers and allows users to auto-enroll for certificates.

# **Keyfactor Android Agent**

This orchestrator runs on Android OS Devices and is used to manage PEM and Java keystores. The orchestrator is distributed as part of the Keyfactor Integration SDK (software development kit). Contact Keyfactor for more information.

# **Keyfactor Native Agent**

This orchestrator is a reference implementation intended for customers wanting to include Keyfactor Command certificate store management functionality in embedded or other platforms. The orchestrator is distributed as part of the Keyfactor Integration SDK (software development kit). Contact Keyfactor for more information.

### **Keyfactor AnyAgent**

The Keyfactor AnyAgent runs on Windows or Linux servers and is used to allow management of certificates regardless of source or location by allowing customers to implement custom agent functionality. Custom store types and/or job capabilities, on which agents operate, are created by adding commands and leveraging extendable code to communicate through an API with Keyfactor Command. Because of the custom nature of the functionality of the AnyAgent, it is not included in the table below, as it could be designed to do one or more of the capacities below, or additional capacities not included below. Contact Keyfactor for more information.

# **Keyfactor Bash Orchestrator**

This orchestrator runs on Linux servers and is used to perform discovery of SSH keys, generation of SSH keys, and management of SSH keys and Linux logons.

Table 16: Orchestrator Capabilities

	Universal	Java	Android	Native	Mac	Bash
Amazon Web Services Add/Re- move	<b>√</b> 1

The options available in the Orchestrator Management section of the Management Portal are:

# **Auto-Registration**

Configure Keyfactor Command to allow orchestrators to auto-register.

# Management

View and configure orchestrators.

### **Jobs**

View active orchestrator jobs and review job errors.

# **Blueprints**

Snapshot the certificate stores and scheduled jobs of one machine and apply them to multiple other similar machines.

### Mac Auto-Enrollment

Configure settings for Mac auto-enrollment.

### 2.1.9.1 Orchestrator Auto-Registration

Orchestrator auto-registration allows you to automatically approve or deny new orchestrators without administrator input, if desired. This is useful in environments hosting a large number of orchestrators. On the Orchestrator Auto-Registration Settings page you define the conditions under which an orchestrator (e.g. Keyfactor Universal Orchestrator or Keyfactor Java Agent) can automatically be approved using the built-in auto-registration system. This is one of two ways that Keyfactor Command supports orchestrator auto-registration. Keyfactor Command also offers an enhanced orchestrator auto-registration system that allows the construction of custom orchestrator auto-approval handler modules. Any custom auto-registration handlers are processed first before the built-in auto-registration system runs. For more information about custom auto-registration handlers, see Custom Auto-Registration Handlers on page 496.

The configurable settings for the built-in auto-registration system are:

· Auto-Register

Should orchestrators be allowed to auto register? If the *Auto-Register* box is checked but the *Validate Users* setting is not checked, any orchestrator that appears in your environment will automatically be approved regardless of origin.

### Validate Users

Do the user accounts under which the orchestrators are running need to be a member of a specific group in order to auto-register (aka validation)?

User Groups

If the user accounts must be a member of a group to auto-register (Validate Users is checked), which group or groups is that (or which user account if all orchestrators will be registering as the same user)? If the Auto-Register setting and the Validate Users settings are both enabled, then this field will be considered. If Validate Users is not checked, this setting will not be displayed.

The default auto-registration settings are to allow no orchestrators to auto-register.

Important: Orchestrator auto-registration in Keyfactor Command is only supported when using Active Directory as an identity provider (see Selecting an Identity Provider for Keyfactor Command in the Keyfactor Command Server Installation Guide). If you need autoregistration with Keyfactor Identity Provider authentication, see Custom Auto-Registration Handlers on page 496.

Tip: Click the help icon (2) next to the page title to open the embedded web copy of the Keyfactor Command Documentation Suite to this section.

You can also find the help icon at the top of the page next to the Log Out button. From here you can choose to open either the Keyfactor Command Documentation Suite at the home page or the Keyfactor API Endpoint Utility.

## **Orchestrator Auto-Registration Settings**

Important: Orchestrator auto-registration in Keyfactor Command is only supported when using Active Directory as an identity provider (see Selecting an Identity Provider for Keyfactor Command in the Keyfactor Command Server Installation Guide). If you need autoregistration with Keyfactor Identity Provider authentication, see Custom Auto-Registration Handlers on page 496.

The Orchestrator Auto-Registration Settings grid shows the current auto-registration settings for any defined certificate store job types, including those for Keyfactor custom-built extensions. The list you will see in your implementation will vary and may include:

# Amazon Web Services Inventory

Auto-register the Keyfactor Windows Orchestrator to allow it to synchronize certificates from AWS locations.

This certificate store type has been deprecated and is no longer in use.

# **Amazon Web Services Management**

Auto-register the Keyfactor Windows Orchestrator to allow it to manage certificates on and deliver certificates to AWS locations.

This certificate store type has been deprecated and is no longer in use.

# CitrixAdc Inventory

Auto-register the Keyfactor Universal Orchestrator to allow it to synchronize certificates from Citrix NetScaler devices.

This type is user-defined for a Keyfactor custom-built extension publicly available on GitHub (see Installing Custom-Built Extensions).

# CitrixAdc Management

Auto-register the Keyfactor Universal Orchestrator to allow it to manage certificates on and deliver certificates to Citrix NetScaler devices.

This type is user-defined for a Keyfactor custom-built extension publicly available on GitHub (see Installing Custom-Built Extensions).

# **F5 CA Bundles REST Discovery**

Auto-register the Keyfactor Universal Orchestrator to allow it to run discovery tasks to locate CA bundles on the F5 device(s).

This type is user-defined for a Keyfactor custom-built extension publicly available on GitHub (see Installing Custom-Built Extensions).

### **F5 CA Bundles REST Inventory**

Auto-register the Keyfactor Universal Orchestrator to allow it to synchronize CA bundles from the F5 device(s).

This type is user-defined for a Keyfactor custom-built extension publicly available on GitHub (see <a href="Installing Custom-Built Extensions">Installing Custom-Built Extensions</a>).

### F5 CA Bundles REST Management

Auto-register the Keyfactor Universal Orchestrator to allow it to manage CA bundles on and deliver certificates to CA bundles on the F5 device(s).

This type is user-defined for a Keyfactor custom-built extension publicly available on GitHub (see Installing Custom-Built Extensions).

# **F5 Certificate Store Inventory**

Auto-register the Keyfactor Windows Orchestrator to allow it to synchronize certificates from the F5 device(s).

This certificate store type has been deprecated and is no longer in use.

# F5 Certificate Store Management

Auto-register the Keyfactor Windows Orchestrator to allow it to manage certificates on and deliver certificates to the F5 device(s).

This certificate store type has been deprecated and is no longer in use.

# F5 Keygen/re-enrollment

Setting reserved for future use.

This certificate store type has been deprecated and is no longer in use.

# **F5 SSL Profiles REST Discovery**

Auto-register the Keyfactor Universal Orchestrator to allow it to run discovery tasks to locate SSL certificates on the F5 device(s).

This type is user-defined for a Keyfactor custom-built extension publicly available on GitHub (see Installing Custom-Built Extensions).

# F5 SSL Profiles REST Inventory

Auto-register the Keyfactor Universal Orchestrator to allow it to synchronize SSL certificates from the F5 device(s).

This type is user-defined for a Keyfactor custom-built extension publicly available on GitHub (see Installing Custom-Built Extensions).

### F5 SSL Profiles REST Management

Auto-register the Keyfactor Universal Orchestrator to allow it to manage SSL certificates on and deliver certificates to the F5 device(s).

This type is user-defined for a Keyfactor custom-built extension publicly available on GitHub (see <a href="Installing Custom-Built Extensions">Installing Custom-Built Extensions</a>).

# **F5 Web Server REST Inventory**

Auto-register the Keyfactor Universal Orchestrator to allow it to synchronize device certificates from the F5 device(s).

This type is user-defined for a Keyfactor custom-built extension publicly available on GitHub (see Installing Custom-Built Extensions).

# F5 Web Server REST Management

Auto-register the Keyfactor Universal Orchestrator to allow it to manage device certificates on and deliver certificates to the F5 device(s).

This type is user-defined for a Keyfactor custom-built extension publicly available on GitHub (see Installing Custom-Built Extensions).

# **File Transfer Protocol Inventory**

Auto-register the Keyfactor Windows Orchestrator or Keyfactor Universal Orchestrator to allow it to synchronize certificates from PEM certificate stores on FTP capable devices.

This certificate store type has been deprecated and is no longer in use.

# File Transfer Protocol Management

Auto-register the Keyfactor Windows Orchestrator or Keyfactor Universal Orchestrator to allow it to manage certificates on and deliver certificates to PEM certificate stores on FTP capable devices.

This certificate store type has been deprecated and is no longer in use.

# **IIS Bound Certificate Inventory**

Auto-register the Keyfactor Universal Orchestrator to allow it to synchronize certificates from the machine certificate stores of Windows servers.

This type is user-defined for a Keyfactor custom-built extension publicly available on GitHub (see Installing Custom-Built Extensions).

### **IIS Bound Certificate Management**

Auto-register the Keyfactor Universal Orchestrator to allow it to manage certificates in and deliver certificates to the machine certificate stores of Windows servers and optionally bind the certificates to Internet Information Services (IIS) web sites.

This type is user-defined for a Keyfactor custom-built extension publicly available on GitHub (see Installing Custom-Built Extensions).

### **IIS Bound Certificate Reenrollment**

Auto-register the Keyfactor Universal Orchestrator to allow it to re-enroll for certificates in and deliver certificates to the machine certificate stores of Windows servers and optionally bind the certificates to Internet Information Services (IIS) web sites.

This type is user-defined for a Keyfactor custom-built extension publicly available on GitHub (see Installing Custom-Built Extensions).

# **IIS Certificate Store Inventory**

Auto-register the Keyfactor Windows Orchestrator or Keyfactor Universal Orchestrator to allow it to synchronize certificates from the machine certificate stores of Windows servers.

This certificate store type has been deprecated and is no longer in use.

# **IIS Certificate Store Management**

Auto-register the Keyfactor Windows Orchestrator or Keyfactor Universal Orchestrator to allow it to manage certificates in and deliver certificates to the machine certificate stores of Windows servers and optionally bind the certificates to Internet Information Services (IIS) web sites.

This certificate store type has been deprecated and is no longer in use.

# IIS Keygen/re-enrollment

This certificate store type has been deprecated and is no longer in use.

# Java Keystore Discovery

Auto-register the Keyfactor Java Agent to allow it to run discovery tasks to locate Java keystores.

# Java Keystore Inventory

Auto-register the Keyfactor Java Agent to allow it to inventory certificates in Java keystores.

# Java Keystore Keygen/re-enrollment

This certificate store type has been deprecated and is no longer in use.

### Java Keystore Management

Auto-register the Keyfactor Java Agent to allow it to manage (add/remove) certificates in Java keystores.

#### Mac Auto-Enrollment

Auto-register users on Apple Macintosh computers running the Keyfactor Mac Auto-Enrollment Agent for auto-enrollment for certificates.

### **NetScaler Certificate Store Inventory**

Auto-register the Keyfactor Windows Orchestrator to allow it to synchronize certificates from NetScaler devices.

This certificate store type has been deprecated and is no longer in use.

# **NetScaler Certificate Store Management**

Auto-register the Keyfactor Windows Orchestrator to allow it to manage certificates on and deliver certificates to NetScaler devices.

This certificate store type has been deprecated and is no longer in use.

# NetScaler Keygen/re-enrollment

This certificate store type has been deprecated and is no longer in use.

# Orchestrator Log Retrieval

Auto-register the Keyfactor Universal Orchestrator or Native Agent to allow it to perform the fetch logs function.

# **PEM Certificate Store Discovery**

Auto-register the Keyfactor Java Agent to allow it to run discovery tasks to locate PEM certificate stores. Apache servers typically use PEM certificate stores.

# **PEM Certificate Store Inventory**

Auto-register the Keyfactor Java Agent to allow it to inventory certificates in PEM certificate stores.

# **PEM Certificate Store Management**

Auto-register the Keyfactor Java Agent to allow it to manage (add/remove) certificates in PEM certificate stores.

# PEM Keygen/re-enrollment

This certificate store type has been deprecated and is no longer in use.

# **Remote Certificate Authority**

Auto-register the Keyfactor Universal Orchestrator to allow it to synchronize certificates from the remote CA(s) to the Keyfactor Command database.

### Remote File DER Discovery

Auto-register the Keyfactor Universal Orchestrator to allow it to run discovery tasks to locate DER certificate stores.

### Remote File DER Inventory

Auto-register the Keyfactor Universal Orchestrator to allow it to inventory certificates in DER certificate stores.

# Remote File DER Management

Auto-register the Keyfactor Universal Orchestrator to allow it to manage (add/remove) certificates in DER certificate stores.

# Remote File JKS Discovery

Auto-register the Keyfactor Universal Orchestrator to allow it to run discovery tasks to locate JKS certificate stores.

# Remote File JKS Inventory

Auto-register the Keyfactor Universal Orchestrator to allow it to inventory certificates in JKS certificate stores.

# Remote File JKS Management

Auto-register the Keyfactor Universal Orchestrator to allow it to manage (add/remove) certificates in JKS certificate stores.

### Remote File PEM Discovery

Auto-register the Keyfactor Universal Orchestrator to allow it to run discovery tasks to locate PEM certificate stores.

# **Remote File PEM Inventory**

Auto-register the Keyfactor Universal Orchestrator to allow it to inventory certificates in PEM certificate stores.

### Remote File PEM Management

Auto-register the Keyfactor Universal Orchestrator to allow it to manage (add/remove) certificates in PEM certificate stores.

### Remote File PKCS#12 Discovery

Auto-register the Keyfactor Universal Orchestrator to allow it to run discovery tasks to locate PKCS#12 certificate stores.

### Remote File PKCS#12 Inventory

Auto-register the Keyfactor Universal Orchestrator to allow it to inventory certificates in PKCS#12 certificate stores.

### Remote File PKCS#12 Management

Auto-register the Keyfactor Universal Orchestrator to allow it to manage (add/remove) certificates in PKCS#12 certificate stores.

### Remote Template Sync

Auto-register the Keyfactor Universal Orchestrator to allow it to synchronize templates from the remote CA(s) to the Keyfactor Command database.

# Secure Shell Management

Auto-register the Keyfactor Bash Orchestrator to allow it to run SSH tasks.

# **SSL Endpoint Compliance**

Auto-register the Keyfactor Universal Orchestrator to allow it to run SSL compliance tasks.

### **SSL Endpoint Discovery**

Auto-register the Keyfactor Universal Orchestrator to allow it to run SSL discovery tasks.

### **SSL Endpoint Monitoring**

Auto-register the Keyfactor Universal Orchestrator to allow it to run SSL monitoring tasks.

### Orchestrator Auto-Registration Settings •

Orchestrator Auto-Registration settings can be used to allow orchestrators to be 'auto-approved' if they meet the defined criteria

Figure 268: Orchestrator Auto-Registration Settings Page

# **Editing Orchestrator Auto-Registration Jobs**

To edit one of the orchestrator job types:

- 1. In the Management Portal, browse to *Orchestrators > Auto-Registration*.
- On the Orchestrator Auto-Registration Settings page, highlight the row in the grid of the job you
  want to edit and click Edit at the top of the grid or right-click the job in the grid and choose Edit
  from the right-click menu.

Figure 269: Orchestrator Auto-Registration Edit

- 3. In the Orchestrator Auto-Registration Settings dialog, check the Auto-Register box if you want orchestrators to be able to auto-register. If you do not enable this, an administrator will need to visit the Orchestrator Management page in the Management Portal and manually approve each orchestrator.
- 4. Check the **Validate Users** box if you want the users under which the orchestrators are running to be a member of a specific Active Directory group in order to auto-register. If you do not enable this but you do enable auto-registration, all orchestrators will auto-register.
  - a. In the **User Groups** field, enter the AD group or groups against which to validate the user accounts in *DOMAIN\group name* format. Multiple groups should be separated by a comma and no space. User accounts may be used if desired.
  - b. Click the **Validate** button to validate the entered group(s).

Note: Validation is only supported on domain-joined Keyfactor Command servers.

5. Click Save.

Important: The same Active Directory group or groups in the primary Keyfactor Command forest must be used for all roles serviced by a given orchestrator type (e.g. Keyfactor Java Agent or Keyfactor Universal Orchestrator). All auto-registration settings must be populated if any are to be used even if all features are not planned for use. For example, if you plan to use, for example, Java keystores but not PEM certificate stores managed by the Keyfactor Java Agent, you still need to populate both the Java keystore and the PEM auto-registration settings to enable auto-registration for the Java Agent to function correctly. Similarly, all auto-registration settings for capabilities supported by your Keyfactor Universal Orchestrator must be populated even if you won't be using all features. Settings reserved for future use do not need to be populated, though doing so will not hurt anything.

### **Custom Auto-Registration Handlers**

With the custom handler system of auto-registration, a handler module is written and compiled into a DLL, which is then registered in the Keyfactor Command configuration and called whenever a new orchestrator performs an initial registration request, provided there are sufficient licenses available to support the orchestrator. The handler then has the flexibility to call out to an external system such as a database or web service or use any other means to determine whether the orchestrator should be approved and what values should be applied for the blueprint, metadata, and orchestrator ClientID.

When an orchestrator first connects to Keyfactor Command, available registration handlers run in sequence to determine if the orchestrator can be automatically approved. A handler will return one of three results: Allow, Deny, and Defer. Handlers are executed in order of registration until one returns Allow or Deny or until all handlers have been executed. Whenever an executed handler returns a response of Defer, the next registered handler will be executed. If any executed handler returns a response of Deny, further processing will cease and the orchestrator will be moved into a Disapproved state. In both of these cases, values returned by the output parameters will be ignored by Keyfactor Command.

### In the event of an Allow response, the following actions will occur:

- The orchestrator will be set to an Approved state.
- If the value for blueprintName corresponds to a valid orchestrator blueprint that can be applied
  to this orchestrator, it is applied. Otherwise, the response is rejected, the orchestrator is left
  with a state of New, and an error is logged.
- If the value for ClientID is non-null, it will be permanently associated with this orchestrator approval. The orchestrator will be expected to provide this value for the ClientMachine field on all future calls.
- If the CSR attribute was provided to the handler, it will be submitted for issuance and the resulting certificate will be returned to the orchestrator.
- If the request results in an issued certificate and the metadata output parameter has values, the valid metadata field values will be associated with the issued certificate.
- If ClientParameters has a value, the parameters will be returned to the orchestrator (but will not be used by Keyfactor Command).

If no handler returns a response aside from Defer, the process will continue to the built-in auto-registration system, and if the orchestrator is not approved at the conclusion of that, the orchestrator will be left in the New state for manual approval.

Figure 270: Orchestrator Auto-Registration Flow

**Tip:** Sample handler source is available as a starting point for creating a custom auto-registration handler. Contact Keyfactor support for assistance.

# 2.1.9.2 Orchestrator Management

Orchestrators (e.g. Keyfactor Universal Orchestrator and Keyfactor Bash Orchestrator) are managed through the Orchestrator Management page. The orchestrator management grid shows every orchestrator that is actively or has historically been in communication with the Keyfactor Command server.

The orchestrator management grid can be sorted in ascending order by clicking on a column header, with the exception of the *Capabilities* column. Click the column header again to reverse the sort order. The grid columns can be arranged in any order desired by click-holding and dragging the header of the column you wish to move. The column widths may also be adjusted by click-holding and dragging the line separating two column headers. By default, disapproved orchestrators are not included in the display. To include them, click the **Include Disapproved** box.

For a description of the columns shown in the orchestrator management grid, see <u>Viewing Orches</u>-trator Details on the next page.

**Tip:** Click the help icon (2) next to the page title to open the embedded web copy of the *Keyfactor Command Documentation Suite* to this section.

You can also find the help icon at the top of the page next to the **Log Out** button. From here you can choose to open either the *Keyfactor Command Documentation Suite* at the home page or the *Keyfactor API Endpoint Utility*.

### **Orchestrator Management Operations**

To select a single row in the orchestrator management grid, click to highlight it and then select an operation from either the top of the grid or the right-click menu. The approve, disapprove, apply blue-print, reset, and request renewal operations can be done on multiple orchestrators at once. To select multiple rows, click the checkbox for each row on which you would like to perform an operation. Then select an operation from the top of the grid. The right-click menu supports operations on only one orchestrator at a time.

# **Viewing Orchestrator Details**

To view details of an orchestrator, double-click the orchestrator, right-click the orchestrator and choose **View Details** from the right-click menu, or highlight the row in the grid and click **View Details** at the top of the grid. The orchestrator details dialog includes this information:

#### Id

The GUID of the orchestrator.

#### **Client Machine**

The host name of the orchestrator machine, either short or fully qualified depending upon how the machine reports itself.

### Identity

The account the orchestrator is using to authenticate to Keyfactor Command, which may or may not be the same as the account under which the orchestrator is running. For example, the Keyfactor Universal Orchestrator service runs as a service account on the orchestrator machine that may be a local account on the machine, the Windows built-in Network Service account, or an Active Directory domain account. If it's an Active Directory account, it will be an account in the forest to which the orchestrator server is joined. The orchestrator's identity to make the connection to the Keyfactor Command server will be a service account for the identity provider configured for Keyfactor Command, which may be Keyfactor Identity Provider, Active Directory, or a federated identity provider. If it's Active Directory, it will be an identity from the forest in which Keyfactor Command is installed, which may be a different forest from the forest in which the orchestrator is installed.

### **Platform**

The platform of the orchestrator—Java for the Java Agent, .NET Core for the Keyfactor Universal Orchestrator, Bash for the Keyfactor Bash Orchestrator, and ObjectiveC for the Mac agent, for example.

### Version

The version number that the orchestrator has reported.

### **Status**

Whether the orchestrator has been approved for operations with the Keyfactor Command server. Newly registered orchestrators show New in this column. Disapproved orchestrators show Disapproved.

### Last Seen

The date and time when the orchestrator last contacted the Keyfactor Command server.

# Capabilities

The target capabilities that are supported by that orchestrator as appropriate for the type of orchestrator. This includes custom capabilities. Some of the follow capabilities have been deprecated and will only be found on upgraded systems. For example:

- AWSCerManA
- CA
- CitrixAdc
- F5-WS-REST
- F5-SL-REST
- F5-CA-REST
- IISU
- JKS
- LOGS
- MacAutoEnrollment
- PEM
- RFJKS
- RFPkcs12
- RFPEM
- SSH
- SSL
- TemplateSync
- WinCert

### **Cert Store Type Short Names**

The column displays a comma-separated list of the certificate stores types associated with each orchestrator. In many cases, the short name matches the capability.

# **Orchestrator Blueprints**

The last blueprint applied to the orchestrator, if any (see Orchestrator Blueprints on page 522).

# **Legacy Thumbprint**

The thumbprint of the certificate previously used by the orchestrator for client certificate authentication before a certificate renewal operation took place (rotating the current thumbprint into the legacy thumbprint). The legacy thumbprint is cleared once the orchestrator successfully registers with a new thumbprint.

### **Current Thumbprint**

The thumbprint of the certificate that Keyfactor Command is expecting the orchestrator to use for client certificate authentication.

### **Authentication Certificate Renewal Request Status**

The last error code, if any, reported from the orchestrator when trying to register a session. This code is cleared on successful session registration.

# **Last Thumbprint Used**

The thumbprint of the certificate that the orchestrator most recently used for client certificate authentication. In most cases, this will match the *Current Thumbprint*.

#### **Last Error Code**

The last error code, if any, reported from the orchestrator when trying to register a session. This code is cleared on successful session registration.

# **Last Error Message**

The last error code, if any, reported from the orchestrator when trying to register a session. This message is cleared on successful session registration.

Figure 271: View Details for an Orchestrator

# **Approving or Disapproving Orchestrators**

When orchestrators first appear in Keyfactor Command, they have a status of New. The orchestrator cannot perform any jobs while it has this status. To approve an orchestrator, highlight the row in the orchestrator management grid and click **Approve** at the top of the grid or right-click the orchestrator in the grid and choose **Approve** from the right-click menu. Once you have approved a Keyfactor Universal Orchestrator or Keyfactor Java Agent, you can schedule jobs for the orchestrator. Once you have approved an SSH Orchestrator, you can configure server groups and servers for that orchestrator and begin scanning servers. Once you have approved a Mac enroll agent, users can enroll for certificates from that Mac. Some orchestrators may be configured for autoapproval via auto-registration (see Orchestrator Auto-Registration on page 486).

To disapprove an orchestrator, highlight the row in the orchestrator management grid and click **Disapprove** at the top of the grid or right-click the orchestrator in the grid and choose **Disapprove** from the right-click menu. When an orchestrator is disapproved, operations with Keyfactor Command can no longer be carried out by this orchestrator.

**Tip:** An orchestrator that has been disapproved can be re-approved. Click the **Include Disapproved** check box at the top of the grid to locate the orchestrator and then approve it again. If an orchestrator that has previously been disapproved in Keyfactor Command reconnects—after an update or corrections of an issue that took it offline, for example—it will not automatically appear as New again. You will need to locate it in the disapproved orchestrators list and Approve it again.

# Generating and Applying Blueprints

To generate a blueprint from an orchestrator, highlight the row in the orchestrator management grid and click **Generate Blueprint** at the top of the grid or right-click the orchestrator in the grid and choose **Generate Blueprint** from the right-click menu. For more information about blueprints, see Orchestrator Blueprints on page 522.

Figure 272: Generate a Blueprint from an Existing Orchestrator

To apply a blueprint to an orchestrator, highlight the row in the orchestrator management grid and click **Apply Blueprint** at the top of the grid or right-click the orchestrator in the grid and choose **Apply Blueprint** from the right-click menu. For more information about blueprints, see <u>Orchestrator Blueprints</u> on page 522.

Figure 273: Apply a Blueprint from a New Orchestrator

### **Orchestrator Reset**

The orchestrator reset and renewal functions are both useful for orchestrator maintenance. The reset function can be used when an orchestrator is in an error state or if you've made some changes on the orchestrator side that necessitate a refresh. The orchestrator reset function:

- Removes all current orchestrator jobs for the selected orchestrator.
- Deletes all associated certificate stores.
- · Sets the orchestrator status to new.
- For orchestrators configured to use client certificate authentication, clears the certificate thumbrints stored for the orchestrator to allow it to be reconfigured with a new certificate.

To reset an orchestrator, highlight the row in the orchestrator management grid and click **Reset** at the top of the grid or right-click the agent in the grid and choose **Reset** from the right-click menu.

Figure 274: Reset an Orchestrator

### **Orchestrator Renewal**

The renewal function is used for orchestrators that are authenticating via client certificate to initiate a client certificate renewal before this would occur automatically based on approaching certificate expiration. The renewal function requests or requires that the orchestrator enroll for a new client authentication certificate on the orchestrator's next session registration. It is used in conjunction with a custom renewal extension on the orchestrator to force the orchestrator to enroll for a new certificate before it would normally do so based on the warning and expiry windows. See *Register a Client Certificate Renewal Extension* in the *Keyfactor Orchestrators Installation and Configuration Guide* for more information and custom renewal extensions on the renewal process.

To request certificate renewal for an orchestrator, highlight the row in the orchestrator management grid and click **Request Renewal** at the top of the grid or right-click the agent in the grid and choose **Request Renewal** from the right-click menu. In the Renewal Status dropdown, select one of the available options:

- None
   Unset the value so that the orchestrator will not request a new client authentication certificate (based on this value).
- Request
   The orchestrator will request a new client authentication certificate when it next registers for a session. Orchestrator activity will be allowed to continue as usual.
- Require
   The orchestrator will request a new client authentication certificate when it next registers for a session. A new session will not be granted and orchestrator activity will not be allowed to continue until the orchestrator acquires a new certificate.

Figure 275: Request Renewal for an Orchestrator

### Viewing Active Jobs for an Orchestrator

To view all the active jobs for an orchestrator, highlight the row in the orchestrator management grid and click **View Jobs** at the top of the grid or right-click the orchestrator in the grid and choose **View Jobs** from the right-click menu. This will take you to the scheduled jobs tab of the orchestrator job status page with the guery field populated by the selected orchestrator.

Figure 276: View Active Jobs for an Orchestrator

# Viewing the Job History for an Orchestrator

To view job history for an orchestrator, highlight the row in the orchestrator management grid and click **View Job Histories** at the top of the grid or right-click the orchestrator in the grid and choose **View Job Histories** from the right-click menu. This will take you to the job history tab of the orchestrator job status page with the query field populated by the selected orchestrator.

#### Orchestrator Job Status 9 Scheduled certificate store orchestrator jobs and all failed orchestrator jobs are displayed in the grids below. Currently scheduled jobs may be cancelled, and failed jobs may be rescheduled from this Note: Certificate Authority schedules can be viewed via the Certificate Authorities page within the PKI Management tab. Scheduled Jobs Job History 1 Comparison Agentid AgentId -eq "45c290d4-9cb5-4311-bc48-926976914c32" EXPAND MESSAGE | RESCHEDULE | ACKNOWLEDGE | ACKNOWLEDGE ALL Total: 1,132 REFRESH Orchestrator Target Schedule Job Type Operation Start Result Status Message KYFAGNT31.keyexample.com bigip14.kevexample.com - Common Every 4 hours F5-SL-RESTInventory 6/15/2021 9:00:00 AM Success Completed KYFAGNT31.keyexample.com bigip14.keyexample.com - Common F5-SL-RESTManagement 6/15/2021 8:52:00 AM Success Completed KYFAGNT31.keyexample.com bigip14.keyexample.com - Common Every 4 hours F5-SL-RESTInventory 6/15/2021 8:52:00 AM Success Completed KYFAGNT31.keyexample.com KYFAGNT31.keyexample.com - US West 2 Every 3 hours AWSInventory 6/15/2021 8:00:00 AM Success Completed KYFAGNT31.keyexample.com websrvr54.keyexample.com - IIS Personal Daily at 7:00 AM IISInventory 6/15/2021 7:00:00 AM Success Completed KYFAGNT31.keyexample.com websrvr83.keyexample.com - IIS Personal Daily at 7:00 AM IISInventory 6/15/2021 7:00:00 AM Success Completed KYFAGNT31.keyexample.com websrvr87.keyexample.com - IIS Personal Daily at 7:00 AM IISInventory 6/15/2021 7:00:00 AM Success Completed KYFAGNT31.kevexample.com ns3.kevexample.com - /nsconfig/ssl Daily at 6:30 AM NetscalerInventory 6/15/2021 6:30:00 AM Success Completed

# Viewing Certificate Stores Associated with an Orchestrator

Daily at 6:30 AM

To view the certificate stores associated with an orchestrator, highlight the row in the orchestrator management grid and click **View Certificate Stores** at the top of the grid or right-click the orchestrator in the grid and choose **View Certificate Stores** from the right-click menu. This will take you to the certificate stores page with the query field populated by the selected orchestrator.

NetscalerInventory

6/15/2021 6:30:00 AM

Success

Completed

Figure 278: View Certificate Stores for an Orchestrator

**Tip:** This option is only useful for orchestrators that have a capability that makes use of certificate stores (e.g. JKS, PEM, IIS, etc. not SSL or SSH).

# **Fetch Logs**

The fetch logs function is designed to retrieve a portion of the tail end of the orchestrator log for easy review. It is supported for both the Keyfactor Universal Orchestrator and the Native Agent.

To schedule a job to fetch the logs, click **Fetch Logs** from the actions buttons at the top of the Orchestrator Management grid or from the right-click menu. The job will be scheduled to run immediately, which means it should complete within a few minutes depending on other activity occurring at the same time. The fetch logs job will appear in Scheduled Jobs under Orchestrator Job Status with a job type of *Fetch Logs* and when complete will appear in Job History (see <u>Job History on page 517</u>).

For Native Agent fetch log jobs, when the job is complete, locate the completed job on the Job History tab and double-click or click **Expand Message** from the right-click menu or at the top of the grid. The job status message details show 4000 characters of the tail end of the log.

To review the log data for logs fetched from a Keyfactor Universal Orchestrator, use the *GET /OrchestratorJobs/JobStatus/Data* Keyfactor API method. See *Get Orchestrator Jobs Job Status Data* in the *Keyfactor API Reference Guide* for more information.

**Tip**: The orchestrator must be approved and have the LOGS capability in order for the *Fetch Logs* function to be enabled.

**Note**: The orchestrator must be configured to write log entries to a file in order for the *Fetch Logs* function to be able to retrieve logs. The Keyfactor Universal Orchestrator does this by default, but the Native Agent needs to be configured appropriately to write to a file in order to support this feature.

To set up logging on the Native Agent, see the Native Agent configuration instructions to configure logging and start the orchestrator with the appropriate logging level to allow for the use of the **Fetch Logs** feature:

https://github.com/Keyfactor/Keyfactor-CAgent

Figure 279: Sample Native Agent Fetch Log Results

**Tip:** If jobs for the Keyfactor Universal Orchestrator fail with messages similar to the following:

2021-08-05 10:47:23.1940

Keyfactor.Orchestrators.JobExecutors.OrchestratorJobExecutor [Debug] - Response status code does not indicate success: 413 (Request Entity Too Large).

at System.Net.Http.HttpResponseMessage.EnsureSuccessStatusCode() in /\_ /src/System.Net.Http/src/System/Net/Http/HttpResponseMessage.cs:line 172

at Keyfactor.Orchestrators.Services.HttpService.SendPostAsync[T](String uri, Object requestData, Dictionary`2 headers) in F:\BuildAgents\Default1\\_ work\24\s\src\OrchestratorServices\HttpService.cs:line 38

This indicates that the amount of data being returned on the job is greater than IIS on the Keyfactor Command server is configured to accept. You will need to make modifications to the IIS settings on your Keyfactor Command server to allow it to accept larger incoming pieces of content. You can do this using the configuration editor built into the IIS management console. Make the setting changes at the Default Web Site level (or other web site, if you installed your Keyfactor Command in an alternate web site). There are three settings that may need modification:

- system.webServer/security/requestFiltering/requestLimits/maxAllowedContentLength
- system.webServer/serverRuntime/uploadReadAheadSize

system.web/httpRuntime/maxRequestLength

The most important of these is <code>maxAllowedContentLength</code>. Set this value to at least 2,500,000 bytes to support the maximum returned data size for the Keyfactor Universal Orchestrator. The default values of 4096 KB for the <code>maxRequestLength</code> and 49,152 for <code>uploadReadAheadSize</code> will probably be sufficient in most environments, unless you are also using SSL scanning (see <code>Monitoring Network Scan Jobs with View Scan Details on page 466)</code>. (The system.webServer values are set in bytes while the system.web values are set in kilobytes.)

Figure 280: Modify IIS Settings for Keyfactor Universal Orchestrator Custom Jobs: maxAllowedContentLength

### Using the Orchestrator Management Search Feature

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an *is null* or *is not null* comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

Each query consists of three parts:

# **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

### ClientMachine

Complete or partial matches with the orchestrator name as listed in the Client Machine field.

#### LastSeen

Orchestrator last contacted the Keyfactor Command server before, after or on a specified date.

#### Platform

Platform matches or doesn't match the referenced platform. Supported platforms are:

- Java (JKS and PEM)
- NET (e.g. F5, Remote File JKS, IIS, Citrix/NetScaler, Remote File PEM, Remote File PKCS#12, and SSL)
- Mac
- Android
- Native
- Bash (SSH)
- Unknown

#### Status

Status matches the selected category—New, Approved or Disapproved.

#### Identity

Complete or partial matches with the account the orchestrator used when registering with the Keyfactor Command server.

#### Capabilities

Capability matches the referenced capability. Supported capabilities, including common Keyfactor custom-built extensions with default capability names, include (plus any custom types you've created):

- AWSCerManA
- CA
- CitrixAdc
- F5-WS-REST
- F5-SL-REST
- F5-CA-REST
- IISU
- JKS
- LOGS
- MacAutoEnrollment
- PEM
- RFJKS
- RFPkcs12
- RFPEM
- SSH
- SSL
- TemplateSync
- WinCert

#### Version

Complete or partial matches with the version the orchestrator reported when registering with the Keyfactor Command server.

# **Comparison Operator**

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Contains (-contains)
- Does not contain (-notcontains)
- Most date and integer fields support:
- Is equal to (-eq)
- Is not equal to (-ne)
- Is less than (-It)
- Is less than or equal to (-le)

- Starts with (-startswith)
- Ends with (-endswith)
- Is null (-eq NULL)
- Is not null (-ne NULL)
- Is greater than (-gt)
- Is greater than or equal to (-ge)
- Is null (-eq NULL)
- Is not null (-ne NULL)

Most Boolean (true/false) fields support:

- Is equal to (-eq)
- Is not equal to (-ne)

- Is null (-eq NULL)
- Is not null (-ne NULL)

# Comparison Value

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

- Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.
- Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

#### **Advanced Searches**

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

#### **Multiple Criteria**

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and

then enter a comparison value, if applicable. Click **Insert** to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

- %TODAY%
   Use the TODAY special value in place of a specific date in date queries. This option supports math operations, so you can use TODAY-10 or TODAY+30. The built-in *Certificates Expiring in 7 Days* collection uses this special value (see Certificate Collection Manager on page 85).
- %ME%
   Use the ME special value in place of a specific domain\user name in queries that match a domain\user name. The built-in My Certificates collection uses this special value (see Certificate Collection Manager on page 85).
- %ME-AN%
   Use the ME-AN special value in place of a specific user name excluding the domain. This is beneficial in environments with multiple domains where there is a desire to query for a user's certificates even if they were requested across multiple domains.

**Important**: The special query options of %TODAY%, %ME%, and %ME-AN% are only supported in uppercase. Lowercase equivalents (e.g. %me%) cannot be substituted.

#### 2.1.9.3 Orchestrator Job Status

The Orchestrator Job Status page provides information on currently scheduled certificate store, SSH, and SSL jobs as well as an audit log of job history.

**Tip:** Click the help icon (**②**) next to the page title to open the embedded web copy of the *Keyfactor Command Documentation Suite* to this section.

You can also find the help icon at the top of the page next to the **Log Out** button. From here you can choose to open either the *Keyfactor Command Documentation Suite* at the home page or the *Keyfactor API Endpoint Utility*.

#### **Scheduled Jobs**

The Scheduled Jobs tab on the Orchestrator Job Status page shows all of the currently scheduled jobs for any approved Android, Java, Native, and SSH Orchestrators and jobs other than remote CA sync for approved Keyfactor Universal Orchestrators (SSL jobs only appear while they are in progress). At a glance, you can see what discovery, inventory, management, and synchronization jobs are scheduled for all the active orchestrators that can communicate with Keyfactor Command.

The Orchestrator Job Status grid includes these fields:

#### Orchestrator

The host on which the orchestrator is running.

# **Target**

The target machine name followed by the path and file name to the certificate store on the target machine for many types of jobs. This field may be blank for some types of jobs.

### Schedule

The time at which or frequency with which a job will run. Add and remove certificate jobs will show *Immediately* unless they have been scheduled for a later time. Renewals and reenrollments will always show *Immediately* since these can't be scheduled for a later time. SSL jobs will always show *Immediately* since they only appear in the grid while they are in progress.

# Job Type

The type of job—e.g. inventory, discovery, management (add and remove certificate), synchronization.

### Requested

The date and time when the job was configured or updated.

The operations available on the Scheduled jobs tab are:

### Unschedule

To unschedule a job, highlight the row for the job in the orchestrator job status grid and click **Unschedule** at the top of the grid or right-click the job in the grid and choose **Unschedule** from the right-click menu.

### **Unschedule All Jobs**

To unschedule multiple jobs, do a search for the jobs you wish to unschedule (e.g. JobType -contains "Discovery") and click **Unschedule All Jobs** at the top of the grid.

If an inventory job for a certificate store is unscheduled, all instances of that job will be removed (as opposed to just the next inventory job) and that store will not be inventoried again until another inventory job is scheduled for it on the Certificate Stores page.

**Tip:** SSL discovery and monitoring jobs and SSH synchronization jobs cannot be unscheduled from this page—this should be done in SSL and SSH management instead (see <u>SSL Discovery</u> on page 454 and SSH Server Groups on page 561).

#### Orchestrator Job Status 9 Scheduled certificate store orchestrator jobs and all failed orchestrator jobs are displayed in the grids below. Currently scheduled jobs may be cancelled, and failed jobs may be rescheduled from this Note: Certificate Authority schedules can be viewed via the Certificate Authorities page within the PKI Management tab Scheduled Jobs Job History 2 Fleld Comparison Value ✓ is equal to SEARCH ADVANCED Agentid UNSCHEDULE ALL JOBS Total: 24 REFRESH Schedule Orchestrator Target Job Type KYFAGNT31.keyexample.com KYFAGNT31.keyexample.com -Once on 6/15/2021 at 9:45 AM F5-SL-RESTDiscovery 6/15/2021 9:36:53 AM KYFAGNT31.keyexample.com bigip14.keyexample.com - Common F5-SL-RESTInventory 6/14/2021 6:30:33 PM KYFAGNT31.keyexample.com 6/14/2021 6:24:25 PM KYFAGNT31.keyexample.com - US West 2 Every 3 hours appsrvr163-SSH-A.keyexample.com appsrvr163-SSH-A.keyexample.com - appsrvr163.keyexample.com Every 30 minutes SshSync appsrvr158-SSH-A.keyexample.com appsrvr158-SSH-A.keyexample.com - appsrvr158.keyexample.com Every 1 hour appsrvr158-SSH-A.keyexample.com appsrvr158-SSH-A.keyexample.com - appsrvr161.keyexample.com appsrvr158-SSH-A.keyexample.com appsrvr158-SSH-A.keyexample.com - appsrvr160.keyexample.com Daily at 9:00 AM appsrvr163-SSH-A.keyexample.com SshSync appsrvr163-SSH-A.keyexample.com Daily at 9:00 AM SshSync appsrvr163-SSH-A.keyexample.com SshSync 6/10/2021 2:45:58 PM appsrvr80.keyexample.com 6/10/2021 11:01:29 AM appsrvr80.keyexample.com appsrvr80.keyexample.com - /opt/app/mystore.jks Every 8 hours JksInventory 6/10/2021 11:01:29 AM Daily at 6:30 AM KYFAGNT31.keyexample.com 6/10/2021 9:53:54 AM ns3.keyexample.com - /nsconfig/ssl NetscalerInventory Daily at 6:30 AM KYFAGNT31.keyexample.com NetscalerInventory 6/10/2021 9:53:54 AM ns2.keyexample.com - /nsconfig/ssl appsrvr162-E.keyexample.com appsrvr80.keyexample.com - /files Every 1 hour FTPInventory 6/10/2021 9:53:33 AM websrvr54-A.keyexample.com ftp93.keyexample.com - / Every 1 hour FTPInventory 6/10/2021 9:53:33 AM

Figure 281: Orchestrator Job Status Scheduled Jobs

### Scheduled Job Search Feature

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an *is null* or *is not null* comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

Each query consists of three parts:

# **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

#### AgentMachine

Complete or partial matches with the orchestrator name as listed in the Orchestrator Machine field.

# TargetPath

Complete or partial matches with the contents of the Target field, including the target machine name and the certificate store path and file name.

#### ScheduleType

Schedule Type matches or does not match the referenced type. Supported schedule types are:

- Immediate
- Interval
- Daily
- Weekly
- Monthly
- Once

#### Requested

Job was requested or updated before, after or on a specified date. Supports the %TODAY% token (see Advanced Searches on page 516).

#### JobType

Job Type contains or doesn't contain the referenced keywords. Supported keywords are:

- Management (including add and remove certificates)
- Inventory
- · Certstore Discovery
- · SSL Discovery
- Reenrollment
- SSL Monitoring
- Sync
- Enrollment

#### AgentType

Orchestrator Type matches the referenced type. Supported orchestrator types, including common Keyfactor custom-built extensions with default names, include (plus any custom types you've created):

- AWSCerManA
- CA
- CitrixAdc
- F5-WS-REST
- F5-SL-REST
- F5-CA-REST
- IISU
- JKS
- LOGS
- MacAutoEnrollment
- PEM
- RFJKS
- RFPkcs12
- RFPEM
- SSH
- SSL
- TemplateSync

WinCert

#### AgentPlatform

Orchestrator Platform matches or doesn't match the referenced platform. Supported platforms are:

- Java (JKS and PEM)
- NET (e.g. F5, Remote File JKS, IIS, Citrix/NetScaler, Remote File PEM, Remote File PKCS#12, and SSL)
- Mac
- Android
- Native
- · Bash (SSH)
- Unknown

#### AgentID

Orchestrator ID matches or doesn't match the entered GUID (primarily used for internally generated searches when the user is redirected here from another page).

# **Comparison Operator**

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Contains (-contains)
- Does not contain (-notcontains)

- Starts with (-startswith)
- Ends with (-endswith)
- Is null (-eq NULL)
- Is not null (-ne NULL)

Most date and integer fields support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Is less than (-It)
- Is less than or equal to (-le)

- Is greater than (-gt)
- Is greater than or equal to (-ge)
- Is null (-eq NULL)
- Is not null (-ne NULL)

Most Boolean (true/false) fields support:

- Is equal to (-eq)
- Is not equal to (-ne)

- Is null (-eq NULL)
- Is not null (-ne NULL)

### **Comparison Value**

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

- Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.
- Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

#### **Advanced Searches**

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

### **Multiple Criteria**

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click **Insert** to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

In addition to the options available in the query builder, three special values can be used in selected searches by typing them in directly:

- %TODAY%
   Use the TODAY special value in place of a specific date in date queries. This option supports math operations, so you can use TODAY-10 or TODAY+30. The built-in *Certificates Expiring in 7 Days* collection uses this special value (see Certificate Collection Manager on page 85).
- %ME%
   Use the ME special value in place of a specific domain\user name in queries that match a

domain\user name. The built-in *My Certificates* collection uses this special value (see <u>Certificates</u> Collection Manager on page 85).

• %ME-AN%

Use the ME-AN special value in place of a specific user name excluding the domain. This is beneficial in environments with multiple domains where there is a desire to query for a user's certificates even if they were requested across multiple domains.

**Important**: The special query options of %TODAY%, %ME%, and %ME-AN% are only supported in uppercase. Lowercase equivalents (e.g. %me%) cannot be substituted.

### **Job History**

The Job History tab on the Orchestrator Jobs page shows a record of discovery, inventory and management jobs for certificate stores, SSH servers, SSL endpoints and remote CAs. It keeps the three most recent inventory jobs, whether they have warnings, failed, or succeeded. Information on potential causes of the problem to allow for troubleshooting is provided for failed jobs.

There are several settings that control the behavior of orchestrator jobs in *Settings > Application Settings-Agent Tab* (see Application Settings: Agents Tab on page 615), most notably:

- Job Failures and Warnings Age Out (days)
- Notification Alert Email Recipients
- Notification Alert Interval (minutes)
- · Number of times a job will retry before reporting failure
- Number of times a job will retry connecting to PAM providers

The operations available on the Job History tab are:

# **Expand Message**

To view the details of an error or warning message, double-click the row for the job in the orchestrator job history grid, right-click the job and choose **Expand Message** from the right-click menu, or highlight the row in the grid and click **Expand Message** at the top of the grid.

#### Reschedule

To reschedule a job, correct the error that caused the problem, then highlight the row for the job in the orchestrator job history grid and click **Reschedule** at the top of the grid or right-click the job in the grid and choose **Reschedule** from the right-click menu.

### Acknowledge [All]

To mark an error or warning grid entry as acknowledged, highlight the row for the job in the orchestrator job history grid and click **Acknowledge** at the top of the grid or right-click the job in the grid and choose **Acknowledge** from the right-click menu. Jobs that are in process or that have completed successfully cannot be marked as acknowledged. Marking a job as acknowledged

removes it from the count on the job history tab (if the job falls within the count period defined by the *Job Failures and Warnings Age Out (days)* application setting—see <u>Application Settings: Agents Tabon page 615</u>).

The small number that appears on the tab to the right of the title indicates how many failures and warnings there have been, if any, within the last seven days, by default, unless the job has been marked as acknowledged. This acts as a reminder to check for failures and warnings. This number of days for reporting is configurable using the *Job Failures and Warnings Age Out (days)* application setting (see Application Settings: Agents Tab on page 615).

Figure 282: Orchestrator Job History

The Job History grid includes these fields:

### Orchestrator

The host on which the orchestrator was running. [All]

# **Target**

The target machine name followed by the path and file name to the certificate store on the target machine for many types of jobs, the endpoint group name for SSL jobs, or the CA name for remote CA jobs. This field may be blank for some types of jobs.

### Schedule

The time at which or frequency with which a job was scheduled to run. Add and remove certificate jobs, will show *Immediately* unless they were scheduled for a later time. Renewal and reenrollment jobs will always show *Immediately* since they don't support later scheduling, as will fetch logs jobs.

### Job Type

The type of job that was run and in some cases the orchestrator type associated with the job (e.g. F5 SSL Profiles Management, PEM File Discovery, Java Keystore Inventory or CA Synchronization).

### **Operation Start**

The time at which the job was run.

### **Operation End**

The time at which the job was completed.

### Result

The outcome of the job—e.g. Success, Failure, or Warning. Under some circumstances—for example, jobs that are still actively running—Unknown may appear here.

### **Status**

The status of the job—e.g. Acknowledged, Completed, CompletedWillRetry, or InProcess. If a job shows as CompletedWillRetry, it has failed at least once, is automatically retrying five times, by default (see the *Number of times a job will retry before reporting failure* in <u>Application Settings:</u> <u>Agents Tab on page 615</u>) and cannot be rescheduled because it is still attempting to run.

### Message

The message indicating the reason for the failure or warning, if applicable. Double-click the grid row or right-click and choose **Expand Message** from the right-click menu to read the error message in full.

**Note**: Currently, any jobs initiated with the **Fetch Logs** function will not be included in any **Job Type** search results, but will be included in any other query search field. See <u>Fetch Logs</u> on page 506 for more information.

**Note:** For Bash Orchestrator message resolution see <u>SSH-Bash Orchestrator Job History</u> Warning Resolution on page 790.

### Job History Search Feature

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an *is null* or *is not null* comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

Each query consists of three parts:

### **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

#### **Status**

Status matches or doesn't match the selected category—Acknowledged, Completed, InProcess, Waiting, Unknown.

#### Result

Result matches or doesn't match the selected category—Failure, Warning, Success, Unknown.

#### Agent

Complete or partial matches with the orchestrator name as listed in the orchestrator field.

#### TargetPath

Complete or partial matches with the contents of the Target field, including the target machine name and the certificate store path and file name for types of jobs listing those, or for SSL jobs, the endpoint group name, or for remote CA synchronization jobs, the CA name.

#### ScheduleType

Schedule Type matches or does not match the referenced type. Supported schedule types are:

- Immediate
- Interval
- Daily
- Weekly
- Monthly
- Once

#### JobType

Job Type matches or does not match the referenced type. Supported categories are:

- Management
- Inventory
- Certstore Discovery
- SSL Discovery
- Reenrollment
- SSL Monitoring
- CA Synchronization

#### OperationStart

Operation Start before or after a specified date and time. Supports the %TODAY% token (see Advanced Searches on the next page).

#### Message

Partial matches with the error or warning message listed in the Message field.

#### AgentID

Agent ID matches or doesn't match the entered GUID (primarily used for internally generated searches when the user is redirected here from another page).

# Comparison Operator

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Contains (-contains)
- Does not contain (-notcontains)

### Most date and integer fields support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Is less than (-It)
- Is less than or equal to (-le)

## Most Boolean (true/false) fields support:

- Is equal to (-eq)
- Is not equal to (-ne)

- Starts with (-startswith)
- Ends with (-endswith)
- Is null (-eq NULL)
- Is not null (-ne NULL)
- Is greater than (-gt)
- Is greater than or equal to (-ge)
- Is null (-eq NULL)
- Is not null (-ne NULL)
- Is null (-eq NULL)
- Is not null (-ne NULL)

# Comparison Value

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

- Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.
- Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

# **Advanced Searches**

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

### **Multiple Criteria**

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click **Insert** to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

In addition to the options available in the query builder, three special values can be used in selected searches by typing them in directly:

- %TODAY%
  - Use the TODAY special value in place of a specific date in date queries. This option supports math operations, so you can use TODAY-10 or TODAY+30. The built-in *Certificates Expiring in 7 Days* collection uses this special value (see <u>Certificate Collection Manager on page 85</u>).
- %ME%
   Use the ME special value in place of a specific domain\user name in queries that match a domain\user name. The built-in My Certificates collection uses this special value (see Certificate Collection Manager on page 85).
- %ME-AN%
   Use the ME-AN special value in place of a specific user name excluding the domain. This is beneficial in environments with multiple domains where there is a desire to query for a user's certificates even if they were requested across multiple domains.

**Important:** The special query options of %TODAY%, %ME%, and %ME-AN% are only supported in uppercase. Lowercase equivalents (e.g. %me%) cannot be substituted.

### 2.1.9.4 Orchestrator Blueprints

The orchestrator blueprint system allows a large number of similar orchestrators to be configured with minimal effort on the part of the user. By taking a snapshot of the certificate stores and scheduled jobs on one orchestrator, matching certificate stores and jobs can be defined on another orchestrator with just a few clicks. With an orchestrator auto-registration handler, blueprint application can even be completely automated, so that a large number of machines or devices can be configured and obtain certificates with no user input after initial configuration of the blueprint and handler. This can greatly improve security by ensuring that each device is provisioned from day one with a unique certificate using a private key generated on the device as well as an up-to-date list of trusted roots, and it allows for continuous monitoring and reporting of all certificates across all configured devices.

Orchestrator blueprints are generated from the Orchestrator Management page (see Orchestrator Management on page 497) and applied to new orchestrators manually via the Orchestrator Management page. On the Orchestrator Blueprints page, you can review the existing blueprints, view details of a blueprint (what certificate stores and scheduled jobs are included in the blueprint), and delete blueprints.

### **Blueprint Operations**

Some blueprint operations are carried out on the Orchestrator Management page (generating and applying blueprints) while others are done on the Orchestrator Blueprints page (viewing and deleting blueprints).

# **Applying Blueprints**

When you apply a blueprint to an orchestrator, you are defining a set of certificate stores and scheduled jobs for that orchestrator as determined by the blueprint at the time that the blueprint is applied. There is no ongoing effect to having a blueprint applied. If the blueprint is deleted, this does not affect the orchestrators to which the blueprint was applied. Likewise, changing the orchestrator from which the blueprint was created after creation of the blueprint does not affect the blueprint. The blueprint continues to contain the certificate stores and scheduled jobs that were associated with the orchestrator at the time the blueprint was taken.

Orchestrator blueprints work with Java and PEM certificate stores and can be used with the Java, Native, and Android agents.

Blueprints are applied to an orchestrator from the Orchestrator Management page (see <u>Generating</u> and Applying Blueprints on page 502).

# **Modifying Blueprints**

Blueprints can't be edited. To modify a blueprint, modify the certificate stores and scheduled jobs on the orchestrator from which the blueprint was taken and capture a new blueprint (see <u>Generating and Applying Blueprints on page 502</u>). This will replace the existing blueprint. An orchestrator can only have one blueprint at a time.

#### Orchestrator Blueprints 9

Figure 283: Orchestrator Blueprints

# **Deleting Blueprints**

To delete a blueprint:

- 1. In the Management Portal, browse to *Orchestrators > Orchestrator Blueprints*.
- 2. On the Orchestrator Blueprints page, select an orchestrator blueprint and click **Delete** from either the top or right-click menu.
- 3. On the Confirm Operation alert, click **OK** to confirm or **Cancel** to cancel the operation.

# **Viewing Blueprint Details**

To view the details of a blueprint:

- 1. In the Management Portal, browse to *Orchestrators > Orchestrator Blueprints*.
- 2. On the Orchestrator Blueprints page, select an orchestrator blueprint and double-click or click **View** from either the top or right-click menu.
- 3. On the Confirm Operation alert, click **OK** to confirm or **Cancel** to cancel the operation.

On the Certificate Stores tab you can see the certificate store paths and types that have been associated with the blueprint. On the Scheduled Jobs tab you can see the scheduled jobs for these certificate stores. These would generally be inventory jobs, though it is possible to blueprint an orchestrator with other types of active jobs (e.g. discovery).

Figure 284: Orchestrator Blueprint Details: Certificate Stores Tab

Figure 285: Orchestrator Blueprint Details: Scheduled Jobs Tab

### 2.1.9.5 Mac Auto-Enrollment

The settings on the Mac Auto-Enrollment page control how Mac auto-enrollment agents in your environment auto-enroll for certificates through Keyfactor Command. The available settings are:

#### **Enabled**

Controls whether Mac auto-enrollment is allowed in the environment.

### Interval

Defines, in minutes, how frequently the agent should check to see if there are new certificates for which to enroll.

#### Use Metadata

If enabled, allows you to automatically associate data in a custom metadata field with an auto-enrolled Mac certificate. See Certificate Metadata on page 712 for more information about metadata fields.

#### Metadata Field Name

Choose an existing metadata string or Boolean field in the dropdown to populate for the certificate, if *Use Metadata* is enabled.

# Metadata Value Type

Determines whether the data inserted in the metadata field will be based on the machine from which the certificate is requested or will be set to the same value for all certificates. Choose *Special Text* to pick from machine-specific values in the Metadata Value dropdown. Choose *Static Value* to enter text that will be populated in every Mac auto-enrollment certificate that is issued.

### Metadata Value

If you select Special Text for the Metadata Value Type, this field will be a dropdown including values that are available from the Mac client. In the current

version of the agent, only the Mac serial number is available. If you select Static Value for the Metadata Value Type, this will be a free-form field in which you can type any text you want to appear in the selected metadata field for all Mac auto-enrolled certificates. If you've selected a Boolean metadata field, you'll have the choice of *True* or *False* for the value.

### Mac Auto-Enrollment

Figure 286: Mac Auto-Enrollment Configuration

To save your changes, click **Save** at the bottom of the page, or to revert to the previous settings without saving, click Undo.

**Tip:** For more information about the Mac Auto-Enrollment Agent, see the separate <u>Mac Auto-Enrollment Guide</u>.

### 2.1.10 SSH

Keyfactor SSH Management is designed to allow organizations to inventory and manage secure shell (SSH) keys across the enterprise. The solution consists of two elements; the SSH functionality on the Keyfactor Command Management Portal and the Keyfactor Bash Orchestrator.

**Important:** SSH management in Keyfactor Command with the Keyfactor Bash Orchestrator is only supported when using Active Directory as an identity provider (see *Selecting an Identity Provider for Keyfactor Command* in the *Keyfactor Command Server Installation Guide*). The SSH option in the Management Portal will only appear when Keyfactor Command is installed using Active Directory as an identity provider (and with a license that supports SSH).

The Keyfactor Bash Orchestrator runs on Linux servers and can be operated in two possible modes:

• The orchestrator is used in *inventory only* mode to perform discovery of SSH public keys and associated Linux user accounts across multiple configured targets.

Figure 287: SSH Key Discovery Flow

• When operated in *inventory and publish policy* mode, the orchestrator can be used to add SSH public keys and Linux user accounts on targets and remove rogue keys that appear without authorization.

Figure 288: SSH User Key Management Flow

As you work with SSH keys in Keyfactor Command, you will need to understand the difference between *users*, *service accounts*, and *logons*:

A user is an account in Keyfactor Command—based on an Active Directory user account—which
has been granted the Keyfactor Command SSH User role permission (see <u>SSH Permissions on</u>
page 598).

A *user* can use the My SSH Key tool (see My SSH Key on page 532) to generate an SSH key pair for himself or herself. This stores the user's SSH public and private key in the Keyfactor Command database. An administrator can then use one of the options in the SSH section of the Management Portal (see Editing Access to an SSH Server on page 580, Editing Access to an SSH Server Group on page 564, or Adding Logons on page 586) to map the *user* record and its associated public key to one or more *logons*, creating new *logons* if needed. For servers

operating in *inventory* and publish policy mode, this will cause the *user*'s public key to be published to the authorized\_keys file(s) for each mapped *logon* on the associated SSH server(s) during the next synchronization job. The *user* downloads the private key of the key pair to his or her machine in the My SSH Key tool and retains it there to allow for SSH connections to the target servers the administrator distributes the matching public key to.

**Note**: If an administrator maps a *user*'s public key to a *logon* for a server that is in *inventory only* mode, nothing will happen. The key will not be published to the server.

**Note:** OpenSSH maintains a file for each user that contains the public keys authorized to connect via SSH. By default, this file is named authorized\_keys. In this document, we refer to this file as *authorized\_keys*, however in your environment, this file may have a different name. The file name used in a given environment is defined in the AuthorizedKeysFile setting in the OpenSSH sshd\_config file.

• A service account is a string representing a service for which an SSH key has been requested through the Service Account Keys page (see <u>Service Account Keys on page 543</u>). It is made up of the *Username* and *Client Hostname* entered during service account key creation in the form servicename@hostname (e.g. myservice@appsrvr12).

**Tip:** The client hostname that makes up part of the service account name is not necessarily an actual server hostname. It is a user-defined reference that can contain any string.

An administrator can use the Service Account Keys page (see Service Account Keys on page 543) to generate an SSH key pair for an application—referenced by a service account name—that makes use of SSH for communication, storing the application's SSH public and private key in the Keyfactor Command database. The administrator needs to store the private key securely on the Linux server where the service account for the application can access it and follow the same procedure as for users to distribute the public key to the appropriate SSH server(s) operating in inventory and publish policy mode.

**Note:** If an administrator maps a *service account*'s public key to a *logon* for a server that is in *inventory only* mode, nothing will happen. The key will not be published to the server.

 A logon is a Linux user account. In most cases for the purposes of SSH management, these are Linux user accounts that have or are intended to have SSH public keys associated with them on managed SSH servers, stored in an authorized\_keys files. However, Linux logons without keys (and which should likely never have keys like "root" or OS-specific accounts like "halt") also appear in Keyfactor CommandSSH management.

Typically, you would initially configure your servers in *inventory only* mode and scan the servers for any existing authorized\_keys files containing SSH public keys. This is the discovery phase. Once the discovery phase is complete for a server or server group, you would then switch it to *inventory and publish policy* mode.

When a server is in *inventory and publish policy* mode, any new keys that appear in its authorized\_keys files in a manner other than by distribution from Keyfactor Command are automatically deleted. This allows administrators to closely control who has access to the servers via SSH. Any keys and authorized\_keys files that were in place before the switch to managed mode are synchronized to Keyfactor Command (see <u>Unmanaged SSH Keys on page 557</u>) but not removed from the Linux server. The administrator can choose to remove them through Keyfactor CommandSSH management once the switch to *inventory and publish policy* mode is made, if desired. Any keys placed on the Linux server via Keyfactor Command once the servers are in *inventory and publish policy* mode are considered managed keys and do not appear on the Unmanaged Keys page.

As SSH servers are scanned for SSH keys during the initial discovery phase, the Linux user accounts associated with these keys are synchronized to Keyfactor Command. These user accounts—logons—can be viewed on the Logons tab under Server Manager. Once each server is switched to *inventory and publish policy* mode, these logons can be managed and additional logons can be added to the Linux servers via Keyfactor CommandSSH management.

**Example:** A large organization has dozens of Linux servers that have historically been accessed using SSH public key authentication. They don't know who has access to which servers using this method or what public keys are out on the servers. To get the keys under control, they first do discovery:

- 1. Install the Keyfactor Bash Orchestrator on one Linux server in the environment.
- 2. Copy the remoteinstall.sh script, containing the public key of the orchestrator service account, from the orchestrator to the first ten Linux targets they want to bring under control.
- 3. On each of the control targets, run the remoteinstall.sh script. This creates a local user account and installs the orchestrator's SSH public key to allow the orchestrator to use SSH to remote into the control target to run inventory and publish policy.
- 4. In the Keyfactor Command Management Portal, approve the new orchestrator (see Approving or Disapproving Orchestrators on page 501).
- In the Management Portal, create at least one server group, setting a scanning schedule
  of every hour (Interval = 1 hour) for the initial discovery phase and leaving the Enforce
  Publish Policy box unchecked (see Adding Server Groups on page 562).

Figure 289: Add SSH Server Group for Discovery

6. In the Management Portal, add one server record for the orchestrator and one for each control target (a total of 11 records added), making them members of the group created in the previous step and selecting the **Inventory Only** radio button on the Basic tab (see Adding SSH Servers on page 578).

Figure 290: Add SSH Server for Discovery

7. After allowing the discovery scans to run, review the logons (see <u>Logons on page 586</u>) and the keys discovered (see <u>Unmanaged SSH Keys on page 557</u>) to see what keys are out on the servers and who they belong to.

Now having a handle on what keys are on these ten target servers plus the orchestrator itself, they are now ready to bring these servers under management. To bring the servers under management, they:

- 1. In the Management Portal, edit the record for the server group and check the Enforce Publish Policy box (see Editing or Deleting an SSH Server on page 580). This change will replicate to all servers in the group.
- 2. In the Management Portal, use the Logons page to remove any Linux user accounts that should not be on the target servers (see Editing or Deleting a Logon on page 589).
- 3. In the Management Portal, use the Unmanaged SSH Keys page to remove any public keys that are no longer needed from the target servers (see Deleting an Unmanaged Key on page 558).

These servers are now ready for ongoing management. The administrator is now ready to do discovery on the next group of servers, for which a second server group should be created.

See further examples in My SSH Key on the next page and Service Account Keys on page 543.

For more information about the orchestrator, see Bash Orchestrator in the Keyfactor Orchestrators Installation and Configuration Guide.

The options available in the SSH section of the Management Portal are:

# My SSH Key

Generate an SSH key pair for the logged on user and download the private key to the local machine. The public key is stored in Keyfactor Command and can be pushed out to Linux client controlled by the Keyfactor Bash Orchestrator to allow the user access to the servers.

# Service Account Keys

Generate an SSH key pair for a service using SSH and download the private key to the local machine. The public key is stored in Keyfactor Command and can be pushed out to Linux servers controlled by the Keyfactor Bash Orchestrator to allow the user access to the servers.

#### **Unmanaged Keys**

Review public SSH keys found during discovery on servers configured to be inventoried by the Keyfactor Bash Orchestrator in *inventory only* mode.

# Server Manager

Manage servers, server groups, server logons for Linux clients, and SSH users controlled by the Keyfactor Bash Orchestrator.

# 2.1.10.1 My SSH Key

On the My SSH Key page, any user with the *SSH User* Keyfactor Command role permission (see <u>SSH Permissions on page 598</u>) can generate an SSH key pair for himself or herself. If the user has previously generated a key pair through Keyfactor Command, it will be displayed here. In this interface a user can view only his or her own key pair; keys for any other Keyfactor Command users are not accessible.

**Example:** An administrator wants to provision new user Zed Adams and grant him access to login via secured SSH using PuTTY to three Linux servers controlled by the Keyfactor Bash Orchestrator. The servers are set to both inventory and publish policy. To accomplish this, the administrator:

- 1. Adds Zed's AD account to the AD group that grants him the SSH User role permission in Keyfactor Command and allows him to login to the Management Portal.
- 2. Directs Zed to login to the Management Portal, go to the My SSH Key page and generate a new key pair (see <u>Generating a New Key on page 537</u>). She instructs him to enter the following information in the form:

Key Type: Ed25519Key Length: 256

• Username: Accept the default (his AD username)

• Email: zed.adams@keyexample.com

Passphrase: A password of Zed's choosing used to secure the private key on download.

• Comment: Zed B. Adams

- 3. Instructs Zed to download the SSH private key and use the PuTTY Key Generator tool to open the key and convert it to the PuTTY format:
  - a. Click **Load** and browse to locate the downloaded private key. This key is named something like SSH-Key-KEYEXAMPLE-zadams.identity.
  - b. In the Parameters section of the page, select **Ed25519** as the type of key to generate.
  - c. Click **Save private key** and save the private key in the PuTTY format (\*.ppk) in a safe location on the local machine.

Figure 291: Use PuTTY Key Generator to Convert Zed's Private Key

4. Uses the Keyfactor Command Management Portal to create Linux logons for Zed on each of the three servers that Zed should have access to and map Zed's new public key to these three logons (see Editing Access to an SSH Server Group on page 564).

Figure 292: Create Logons and Mappings for Zed

**Note:** The three servers that Zed needs access to are in a server group so the administrator can create Zed's logons and map his key using the Access Management option on the Server Group page. If the servers were in different server groups or the server group contained servers to which Zed should not have access, the administrator would need to create the logons and mappings separately for each server using the Access Management option on the Servers page (see Editing Access to an SSH Server on page 580).

- 5. Waits for the logons to be created on the three servers and the public key to be published to them. The time that this takes depends on the frequency of the server group synchronization schedule (see Adding Server Groups on page 562).
- 6. Instructs Zed to configure PuTTY to use the private key for authentication, providing also connection information for the three Linux servers to which he will be connecting.

Figure 293: Configure PuTTY to Use Zed's Private Key

7. Confirms that Zed is able to successfully connect using secured SSH to each of the three servers.

This information is included for a key:

### **Creation Date**

The date on which the SSH key pair was generated.

# Stale Date

The date on which the SSH key pair is considered to have reached the end of its lifetime. By default, the lifetime of an SSH key pair is 365 days (see Application Settings: SSH Tab on page 621).

# **Key Type**

A number of cryptographic algorithms can be used to generate SSH keys. Keyfactor Command supports RSA, Ed25519, and ECDSA. RSA keys are more universally supported, and this is the default key type when generating a new key.

# **Key Length**

The key length available when generating a new key depends on the key type selected. Keyfactor Command supports 256 bits for Ed25519 and ECDSA and 2048 or 4096 bits for RSA. The default key length is 2048.

### **Email**

The email address of the user requesting the key. This email address is used to alert the user when the key pair is approaching the end of its lifetime (see Key Rotation Alerts on page 203).

#### Comment

The user-defined descriptive comment, if any, on the key. Although entry of an email address in the comment field of an SSH key is traditional, this is not a required format. The comment may can contain any characters supported for string fields, including spaces and most punctuation marks.

# SHA256 Fingerprint

The fingerprint of the public key. Each SSH public key has a single cryptographic fingerprint that can be used to uniquely identify the key.

# **Public Key**

The public key of the key pair.

# My SSH Key <sup>€</sup>

View and manage my SSH key.

Figure 294: Key Information for an SSH User Key

Tip: Click the help icon (2) next to the page title to open the embedded web copy of the Keyfactor Command Documentation Suite to this section.

You can also find the help icon at the top of the page next to the **Log Out** button. From here you can choose to open either the Keyfactor Command Documentation Suite at the home page or the Keyfactor API Endpoint Utility.

# Generating a New Key

Important: A given user can only have one SSH key pair in Keyfactor Command. Generating a new key pair removes the existing key pair from Keyfactor Command, if one exists. This means any mappings between the Keyfactor user and Linux logon accounts will be updated with the public key from the new key pair. This essentially invalidates the user's previous private key for servers managed with the Keyfactor Bash Orchestrator. Although the Generate button is not active for users who already have a key pair, the Rotate button will also remove the existing key pair.

To generate a new SSH key pair:

- 1. In the Management Portal, browse to SSH > My SSH Key.
- 2. On the My SSH Key page, click Generate.

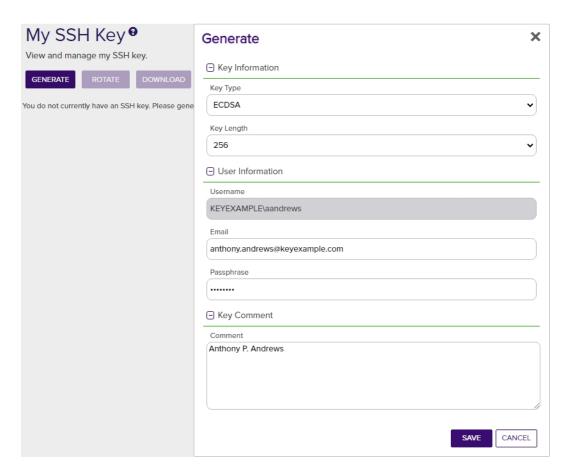

Figure 295: Generate an SSH Key Pair

3. In the Key Information section of the Generate dialog, select a **Key Type** in the dropdown (see Key Type on page 535).

- 4. In the Key Information section, select a **Key Length** in the dropdown (see Key Length on page 535). The available key lengths will vary depending upon the option selected in the Key Type dropdown.
- 5. In the User Information section, confirm that the displayed Username matches the Active Directory user name you wish to associate with your key. This field defaults to your logged in username and cannot be edited.
- 6. In the User Information section, enter an Email address. This address is used for key rotation alerts (see Key Rotation Alerts on page 203). This field is required.
- 7. In the User Information section, enter a Passphrase to encrypt the downloaded copy of the private key of the key pair. You will need to provide this passphrase again when you use the private key to connect via SSH. By default, the minimum password length is 12 characters (see the SSH Key Password setting in Application Settings: SSH Tab on page 621). This field is required.

Tip: Your private key downloads immediately at the conclusion of the generation process, encrypted with this passphrase. You may later download the private key again from this same page and encrypt it with a different passphrase, if desired.

8. In the Key Comment section, enter a **Comment** to include with the key. This field is optional.

Tip: Although entry of an email address in the comment field of an SSH key is traditional, this is not a required format. The comment may contain any characters supported for string fields, including spaces and most punctuation marks.

9. Click **Save** to create the key pair.

Tip: Once the key pair is generated, the user needs to download the private key as an encrypted file and store it locally and an administrator needs to use Keyfactor Command to associate the user's Keyfactor user account with his or her Linux logon account on the target server that the user wishes to access via SSH. After this is complete and the orchestrator has published the user's public key to the target server, the user may connect via SSH to the target server using the new private key for authentication. For more information, see SSH on page 526.

# Rotating a Key

The rotate key option is used to replace an existing key that is approaching the end of its life or has been compromised. If key rotation alerts have been configured in the environment (see Key Rotation Alerts on page 203), the user will receive an email when the key is approaching the end if its lifetime to instruct the user to rotate his or her keys.

**Important:** A given user can only have one SSH key pair in Keyfactor Command. Generating a new key pair with the rotate option removes the existing key pair from Keyfactor Command. This means any mappings between the Keyfactor user and Linux logon accounts will be updated with the public key from the new key pair. This essentially invalidates the user's previous private key for servers managed with the Keyfactor Bash Orchestrator.

The rotate dialog defaults to all the existing settings of the user's current key. At its simplest, users may choose to accept all the defaults, enter a passphrase to encrypt the downloaded private key and click save to generate the new key pair.

To rotate an SSH key pair:

- 1. In the Management Portal, browse to SSH > My SSH Key.
- 2. On the My SSH Key page, click Rotate.

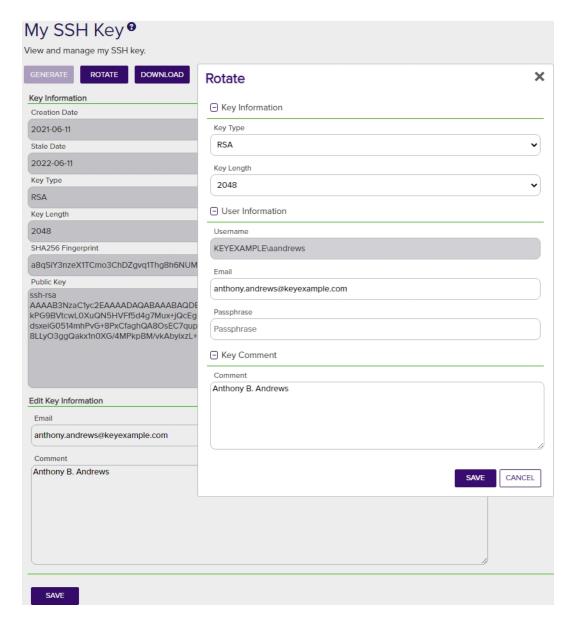

Figure 296: Rotate an SSH Key Pair

- 3. In the Key Information section of the Rotate dialog, modify the existing **Key Type** in the drop-down, if desired (see <u>Key Type on page 535</u>).
- 4. In the Key Information section, modify the existing **Key Length** in the dropdown, if desired (see <u>Key Length on page 535</u>). The available key lengths will vary depending upon the option select in the Key Type dropdown.

- 5. In the User Information section, confirm that the displayed **Username** matches the Active Directory user name you wish to associate with your key. This field defaults to your logged in username and cannot be edited.
- 6. In the User Information section, modify the existing Email address, if desired. This address is used for key rotation alerts (see Key Rotation Alerts on page 203). This field is required.
- 7. In the User Information section, enter a Passphrase to encrypt the downloaded copy of the private key of the key pair. You will need to provide this passphrase again when you use the private key to connect via SSH. By default, the minimum password length is 12 characters (see the SSH Key Password setting in Application Settings: SSH Tab on page 621). This field is required.
- 8. In the Key Comment section, modify the existing Comment to include with the key, if desired. This field is optional.

Tip: Although entry of an email address in the comment field of an SSH key is traditional, this is not a required format. The comment may can contain any characters supported for string fields, including spaces and most punctuation marks.

9. Click Save to create the new key pair.

Tip: Once the key pair is generated, the user needs to download the private key as an encrypted file and store it locally and an administrator needs to use Keyfactor Command to associate the user's Keyfactor user account with his or her Linux logon account on the target server that the user wishes to access via SSH. After this is complete and the orchestrator has published the user's public key to the target server, the user may connect via SSH to the target server using the new private key for authentication. For more information, see SSH on page 526.

# Downloading a Key

After generating a key pair, you need to download the private key on the machine from which you will be making SSH connections. Although the private key is encrypted, for best security practice it should not be moved around from machine to machine.

The key downloads in the proprietary OpenSSH private key format, encrypted by a user-defined password.

Only the private key can be downloaded with the download option, though the public key is displayed on the screen and may be copied and pasted to a file, if desired.

To download the private key:

- 1. In the Management Portal, browse to SSH > My SSH Key.
- 2. On the My SSH Key page, confirm that you have been issued a key pair and click Download.

3. In the Download dialog, enter a passphrase that will be used to encrypt the private key. By default, the minimum password length is 12 characters (see the *SSH Key Password* setting in Application Settings: SSH Tab on page 621). This field is required.

Figure 297: Add a Password to Encrypt the Downloaded Private Key

4. Click **Download** to save the file to your local machine.

By default, the file has the following name, where *DOMAIN* is your Active Directory domain name and *username* is the Active Directory user name of the user logged into the Keyfactor Command Management Portal:

SSH-Key-DOMAIN-username.identity

# **Editing Key Information**

Once you have generated an SSH key pair, most things about the key pair are fixed and cannot be changed. However, two pieces of key information can be changed for an existing key pair—the email address to which alerts about the key should be directed and the comment associated with the public key.

To modify the email address or key comment:

- 1. In the Management Portal, browse to SSH > My SSH Key.
- 2. On the My SSH Key page, update the fields in the Edit Key Information section as needed and click **Save**.

Figure 298: Edit SSH User Key Information

Changes made to the key comment will be published to any associated servers during the next synchronization cycle.

# 2.1.10.2 Service Account Keys

On the Service Account Keys page, an administrator can view and download existing keys issued for service accounts and generate new key pairs.

**Example**: An administrator wants to generate a new SSH key pair for the green chicken application, which is a Linux-based log aggregation application. The application uses secure

SSH to communicate internally between the server collecting the logs and the servers from which the logs are being collected. All the servers are controlled by the Keyfactor Bash Orchestrator. The servers are set to both inventory and publish policy. To accomplish this, the administrator:

1. Uses the Keyfactor Command Management Portal to create a new key pair (see Creating a Service Account Key on page 546). She enters the following information in the form:

 Key Type: Ed25519 • Key Length: 256

• Server Group: Server Group One

The server group to which the Linux servers belong that the public key will be distributed to.

• Client Hostname: appsrvr75

The Linux server on which the private key of the SSH key pair will be download. This does not need to be a server added for management in Keyfactor Command and is a field for reference only.

• Username: svc\_greenchicken

The service account name the application uses. This does not need to match the Linux logon name the application uses. This username together with the client hostname make the full user name for the service account key within Keyfactor Command svc\_greenchicken@appsrvr75.

• Email: pkiadmins@keyexample.com

The group responsible for rotating the key when it reaches the end of its lifetime. This group will receive email alerts when the key is becoming stale.

- Passphrase: A complex password used to secure the private key.
  - She needs to record the passphrase because this will be needed by application to access the private key.
- Comment: Green Chicken Service

Figure 299: Acquire a New Service Account Key

- 2. Downloads the SSH private key on the server doing the log collection, from which the SSH connections will be made to collect logs.
- Uses the Management Portal to map the new public key for the full service account user name (svc\_greenchicken@appsrvr75) to the Linux logons for the service on the servers from which the logs will be collected (see <u>Editing Access to an SSH Server Group on page 564</u>).

Figure 300: Map Service Account Public Key to Logon

Note: The servers that the logs will be collected from are organized into a server group so the administrator can create logons and map the service account key using the Access Management option on the Server Group page. If the servers were in different server groups or the server group contained servers which should not be updated with logons and keys for the green chicken service, the administrator would need to create the logons and mappings separately for each server using the Access Management option on the Servers page (see Editing Access to an SSH Server on page 580).

- 4. Waits for the public key to be published to the servers. The time that this takes depends on the frequency of the server group synchronization schedule (see Adding Server Groups on page 562).
- 5. Confirms that the service is able to successfully connect using secured SSH.

Tip: Click the help icon (2) next to the page title to open the embedded web copy of the Keyfactor Command Documentation Suite to this section.

You can also find the help icon at the top of the page next to the Log Out button. From here you can choose to open either the Keyfactor Command Documentation Suite at the home page or the Keyfactor API Endpoint Utility.

#### Creating a Service Account Key

To create a new service account key:

- 1. In the Management Portal, browse to SSH > Service Account Keys.
- 2. On the Service Account Keys page, click Create.

Figure 301: Add a Service Account Key

- In the Key Information section of the Create dialog, select a Key Type in the dropdown (see <u>Key Type on page 535</u>).
- 4. In the Key Information section, select a **Key Length** in the dropdown (see <u>Key Length on page 535</u>). The available key lengths will vary depending upon the option select in the Key Type dropdown.
- 5. In the Key Information section, select a **Server Group** in the dropdown (see <u>SSH Server Groups on page 561</u>). The server group is used to control who has access in the Management Portal to the service account key. It does not limit where the key can be published. This field is required.
- 6. In the Key Information section, enter a **Client Hostname** reference for the service account key. This field is used for reference only and does not need to match an actual client hostname. It is

used when building the full user name of the service account key for mapping to Linux logons for publishing to Linux servers (e.g. username@client\_hostname). The naming convention is to enter the hostname of the server on which the application that will use the private key resides (e.g. appsrvr12), but you can put anything you like in this field (e.g. cheesetoast). This field is required.

- 7. In the User Information section of the page, enter the **Username** of the service account that will be using the key to connect to the target server (e.g. svc\_myapp). This username will be combined with the Client Hostname to build the full user name of the service account key for mapping to Linux logons (e.g. svc\_myapp@appsrvr12). You will need to know this full user name when creating the mappings to publish the public key to the target servers (see Editing Access to an SSH Server Group on page 564, Editing Access to an SSH Server on page 580, Adding Logons on page 586, or Editing or Deleting a Logon on page 589). This field is required.
- 8. In the User Information section of the page, enter the Email address of the administrator or group of administrators responsible for managing the key. This is the address to which key rotation alerts for this key will be directed (see Key Rotation Alerts on page 203). This field is required.
- 9. In the User Information section, enter a Passphrase to encrypt the downloaded copy of the private key of the key pair. The service that uses the private key will need to be able to provide it when connecting via SSH. By default, the minimum password length is 12 characters (see the SSH Key Password setting in Application Settings: SSH Tab on page 621). This field is required.

Tip: The private key downloads immediately at the conclusion of the creation process, encrypted with this passphrase. You may later download the private key again from this same page and encrypt it with a different passphrase, if desired.

10. In the Key Comment section, enter a **Comment** to include with the key. This field is optional.

Tip: Although entry of an email address in the comment field of an SSH key is traditional, this is not a required format. The comment may contain any characters supported for string fields, including spaces and most punctuation marks.

11. Click **Save** to save the new service account key.

Tip: Once the key pair is generated, an administrator needs to download the private key as an encrypted file and store it locally on the machine from which the service will make SSH connections using the private key. Additionally, an administrator needs to use Keyfactor Command to map the full user name built from the username and client hostname entered when generating the service account key pair (e.g. svc\_myapp@appsrvr12) to the Linux logon account that the service account will operate as when logging in via SSH on the target server(s) where the public key needs to reside (see Editing Access to an SSH Server Group on page 564, Editing Access to an SSH Server on page 580, Adding Logons on page 586, or Editing or Deleting a Logon on page 589). After this is complete and the orchestrator has published the public key to the target

server(s), the service may connect via SSH to the target server(s) using the new private key for authentication. For more information, see SSH on page 526.

# **Editing Service Account Key Information**

Once you have generated an SSH key pair, most things about the key pair are fixed and cannot be changed. However, two pieces of key information can be changed for an existing key pair—the email address to which alerts about the key should be directed and the comment associated with the public key.

Tip: Only service account keys belonging to server groups that the current user is the owner on appear in the grid unless the user holds the SSH Enterprise Admin role.

To modify the email address or key comment:

- 1. In the Management Portal, browse to SSH > Service Account Keys.
- 2. On the Service Account Keys page, double-click the key for the desired service account in the grid, highlight the row in the grid and click Edit at the top of the grid, or right-click the key in the grid and choose Edit from the right-click menu.
- 3. In the Edit Key dialog, update the Email and Comment fields as needed and click Save.

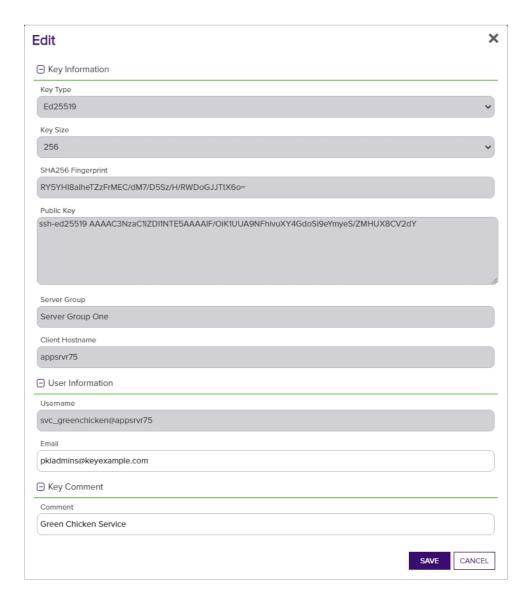

Figure 302: Edit SSH Service Account Key Information

Changes made to the key comment will be published to any mapped logons on associated servers during the next synchronization cycle.

# **Rotating a Service Account Key**

The rotate key option is used to replace an existing key that is approaching the end of its life or has been compromised. If key rotation alerts have been configured in the environment (see <a href="Key Rotation Alerts on page 203">Key Rotation Alerts on page 203</a>), the administrator responsible for managing the service account key will receive an email when the key is approaching the end if its lifetime to instruct the him or her to rotate the service account key.

Important: A given service account can only have one SSH key pair in Keyfactor Command. Generating a new key pair with the rotate option removes the existing key pair from Keyfactor Command. This means any mappings between the Keyfactor service account and Linux logon accounts will be updated with the public key from the new key pair. This essentially invalidates the service account's previous private key for servers managed with the Keyfactor Bash Orchestrator.

The rotate dialog defaults to all the existing settings of the service account's current key. At its simplest, the administrator may choose to accept all the defaults, enter a passphrase to encrypt the downloaded private key and click save to generate the new key pair.

To rotate a service account key pair:

- 1. In the Management Portal, browse to SSH > Service Account Keys.
- 2. On the Service Account Keys page, click Rotate.

Figure 303: Rotate an SSH Key Pair

- In the Key Information section of the Rotate dialog, modify the existing Key Type in the dropdown, if desired (see <u>Key Type on page 535</u>).
- 4. In the Key Information section, modify the existing **Key Length** in the dropdown, if desired (see <u>Key Length on page 535</u>). The available key lengths will vary depending upon the option select in the Key Type dropdown.
- 5. In the User Information section, modify the existing **Email** address, if desired. This address is used for key rotation alerts (see Key Rotation Alerts on page 203). This field is required.

- 6. In the User Information section, enter a Passphrase to encrypt the downloaded copy of the private key of the key pair. You will need to provide this passphrase again when you use the private key to connect via SSH. By default, the minimum password length is 12 characters (see the SSH Key Password setting in Application Settings: SSH Tab on page 621). This field is required.
- 7. In the Key Comment section, modify the existing **Comment** to include with the key, if desired. This field is optional.

Tip: Although entry of an email address in the comment field of an SSH key is traditional, this is not a required format. The comment may can contain any characters supported for string fields, including spaces and most punctuation marks.

8. Click Save to create the new key pair.

Tip: Once the key pair is generated, an administrator needs to download the private key as an encrypted file and store it locally on the machine from which the service will make SSH connections using the private key. Additionally, an administrator needs to use Keyfactor Command to map the full user name built from the username and client hostname entered when generating the service account key pair (e.g. svc\_myapp@appsrvr12) to the Linux logon account that the service account will operate as when logging in via SSH on the target server(s) where the public key needs to reside (see Editing Access to an SSH Server Group on page 564, Editing Access to an SSH Server on page 580, Adding Logons on page 586, or Editing or Deleting a Logon on page 589). After this is complete and the orchestrator has published the public key to the target server(s), the service may connect via SSH to the target server(s) using the new private key for authentication. For more information, see SSH on page 526.

# **Deleting a Service Account Key**

To delete a service account key, highlight the row in the service account keys grid and click Delete at the top of the grid or right-click the key in the grid and choose **Delete** from the right-click menu.

Tip: Only service account keys belonging to server groups that the current user is the owner on appear in the grid unless the user holds the SSH Enterprise Admin role.

# **Downloading a Service Account Key**

After generating a key pair, you need to download the private key on the machine from which you will be making SSH connections. Although the private key is encrypted, for best security practice it should not be moved around from machine to machine.

The key downloads in the proprietary OpenSSH private key format, encrypted by a user-defined password.

Only the private key can be downloaded with the download option, though the public key is displayed in the edit dialog and may be copied and pasted to a file, if desired.

**Tip:** Only service account keys belonging to server groups that the current user is the owner on appear in the grid unless the user holds the *SSH Enterprise Admin* role.

To download the private key:

- 1. In the Management Portal, browse to SSH > Service Account Keys.
- On the Service Account Keys page, locate the key for the desired service account and click Download.

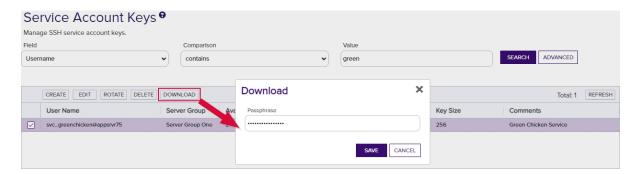

Figure 304: Download a Service Account Private Key

- 3. In the Download dialog, enter a passphrase that will be used to encrypt the private key. By default, the minimum password length is 12 characters (see the *SSH Key Password* setting in Application Settings: SSH Tab on page 621). This field is required.
- 4. Click **Download** to save the file to the local machine.

By default, the file has the following name:

SSH-Key-Service-Account.identity

# Using the Service Account Key Search

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an *is null* or *is not null* comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

**Tip:** Only service account keys belonging to server groups that the current user is the owner on appear in the grid unless the user holds the *SSH Enterprise Admin* role.

Each query consists of three parts:

# **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

#### ServerGroupName

Complete or partial matches with the name of the server group that the service account key is associated with.

#### Username

Complete or partial matches with the username of the service account key. The username is made up of the username and client hostname entered when the service account key was created (e.g. myap-p@appsrvr75).

#### CreationDate

The date on which the key was created.

#### KeyType

Whether the key is RSA, ECC, or Ed25519

#### KeyLength

The key size of the key.

#### Comments

Complete or partial matches with the user-defined comments on the key.

# Comparison Operator

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Contains (-contains)
- Does not contain (-notcontains)
- Most date and integer fields support:
- Is equal to (-eq)
- Is not equal to (-ne)
- Is less than (-It)
- Is less than or equal to (-le)

- Starts with (-startswith)
- Ends with (-endswith)
- Is null (-eq NULL)
- Is not null (-ne NULL)
- Is greater than (-gt)
- Is greater than or equal to (-ge)
- Is null (-eq NULL)
- Is not null (-ne NULL)

Most Boolean (true/false) fields support:

Is equal to (-eq)

• Is null (-eq NULL)

Is not equal to (-ne)

• Is not null (-ne NULL)

# Comparison Value

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

- Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.
- Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

#### Advanced Searches

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

#### **Multiple Criteria**

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click **Insert** to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

# 2.1.10.3 Unmanaged SSH Keys

When your SSH servers are configured in inventory only mode doing discovery, keys discovered on the servers are considered unmanaged and are displayed on the Unmanaged Keys page.

On this page you can review the discovered keys to get a sense of what's out there. You can view the keys, key comments, fingerprint, type and length. Once you switch your servers to inventory and publish policy mode, deleting a key from the unmanaged keys page will also delete the key from the server(s) in this mode on which it is found.

**Note**: Deleting a key on this page when the associated server is still in inventory only mode will *not* delete the key on the target server. The next time the server is scanned, the key will re-appear in Keyfactor Command.

As you bring your servers under management, clean up old keys, and control installation of new keys, the number of keys appearing on the unmanaged keys page should begin to diminish. Eventually, the page should be empty when all your servers have been brought under management and all old keys have been replaced with new, managed, keys.

**Tip:** Click the help icon (②) next to the page title to open the embedded web copy of the *Keyfactor Command Documentation Suite* to this section.

You can also find the help icon at the top of the page next to the **Log Out** button. From here you can choose to open either the *Keyfactor Command Documentation Suite* at the home page or the *Keyfactor API Endpoint Utility*.

### Viewing Unmanaged SSH Keys

To view details for an unmanaged public key, double-click the key, right-click the key and choose **View** from the right-click menu, or highlight the row in the unmanaged keys grid and click **View** at the top of the grid.

The view dialog includes two tabs:

• On the Basic tab, you can see information about the key itself, including the key length, finger-print, comments associated with the key, and the public key itself.

Figure 305: View Basic Tab of an Unmanaged SSH Key

• On the Logon tab, you can view Linux logon names and servers mapped to the public key.

Figure 306: View Logon Tab of an Unmanaged SSH Key

# Deleting an Unmanaged Key

To delete an unmanaged key, highlight the row in the unmanaged keys grid and click **Delete** at the top of the grid or right-click the key in the grid and choose **Delete** from the right-click menu.

**Note**: When you delete an unmanaged key that's found on any servers operating in inventory and publish policy mode (see  $\underline{SSH}$  on page 526), the key will be removed from the target servers as well as from Keyfactor Command.

# Using the Unmanaged Keys Search

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an *is null* or *is not null* comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

Each query consists of three parts:

# **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

DiscoveredDate	KeyLength
The date on which the key was discovered.	The key size of the key.
KeyComments	КеуТуре
Complete or partial matches with the user-defined	Whether the key is RSA, ECC, or Ed25519

# **Comparison Operator**

• Is equal to (-eq)

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the equivalent query language syntax (in parentheses).

• Starts with (-startswith)

Most string fields (the vast majority of the built-in fields) support:

<ul> <li>Is not equal to (-ne)</li> </ul>	<ul> <li>Ends with (-endswith)</li> </ul>
<ul> <li>Contains (-contains)</li> </ul>	<ul><li>Is null (-eq NULL)</li></ul>
<ul> <li>Does not contain (-notcontains)</li> </ul>	<ul> <li>Is not null (-ne NULL)</li> </ul>
Most date and integer fields support:	
• Is equal to (-eq)	<ul> <li>Is greater than (-gt)</li> </ul>
<ul> <li>Is not equal to (-ne)</li> </ul>	• Is greater than or equal to (-ge)
<ul> <li>Is less than (-lt)</li> </ul>	<ul> <li>Is null (-eq NULL)</li> </ul>
<ul> <li>Is less than or equal to (-le)</li> </ul>	<ul> <li>Is not null (-ne NULL)</li> </ul>
Most Boolean (true/false) fields support:	
• Is equal to (-eq)	<ul><li>Is null (-eq NULL)</li></ul>

Is not null (-ne NULL)

# Comparison Value

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

- Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.
- Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

# **Advanced Searches**

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

#### Multiple Criteria

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click **Insert** to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

In addition to the options available in the query builder, three special values can be used in selected searches by typing them in directly:

%TODAY%
 Use the TODAY special value in place of a specific date in date queries. This option supports math operations, so you can use TODAY-10 or TODAY+30. The built-in *Certificates Expiring in 7 Days* collection uses this special value (see Certificate Collection Manager on page 85).

- %ME%
   Use the ME special value in place of a specific domain\user name in queries that match a domain\user name. The built-in My Certificates collection uses this special value (see Certificate Collection Manager on page 85).
- %ME-AN%
   Use the ME-AN special value in place of a specific user name excluding the domain. This is beneficial in environments with multiple domains where there is a desire to query for a user's certificates even if they were requested across multiple domains.

**Important**: The special query options of %TODAY%, %ME%, and %ME-AN% are only supported in uppercase. Lowercase equivalents (e.g. %me%) cannot be substituted.

### 2.1.10.4 Server Manager

SSH key management is performed by one or more Keyfactor Bash Orchestrators controlling multiple targets. These are referred to collectively in the Management Portal as SSH servers. The SSH servers are collected together into one or more server groups. On the Server Manager page you first create one or more server groups to organize and set policies for your Linux SSH servers and then add an SSH server entry for each server you want to control with the orchestrator.

Scanning jobs are configured at the server group level. You can toggle between *inventory only* mode and *inventory and publish policy* mode at either the server group level or on an individual server basis, though if a server group is in *inventory and publish policy* mode (configured to *Enforce Publish Policy*), servers in this group cannot be in *inventory only* mode.

Scanning of targets cannot take place until they have been set up for control by the orchestrator (see *Install Remote Control Targets* in the *Keyfactor Orchestrators Installation and Configuration Guide*).

**Tip:** If you plan to scan and manage your orchestrator machine(s) in addition to any targets, you will need to add SSH server entries for these as though they were targets.

Once the scanning has begun, you can look at the Logons tab to see discovered logons from the targets and associated SSH public keys.

**Tip:** Click the help icon (②) next to the page title to open the embedded web copy of the *Keyfactor Command Documentation Suite* to this section.

You can also find the help icon at the top of the page next to the **Log Out** button. From here you can choose to open either the *Keyfactor Command Documentation Suite* at the home page or the *Keyfactor API Endpoint Utility*.

# **SSH Server Groups**

On the Server Groups tab of the Server Manger page you create server groups that allow you to organize SSH servers and set synchronization schedules and management policies on a group level.

You must create at least one server group before you can add SSH servers into the Keyfactor Command Management Portal.

Figure 307: SSH Server Groups Grid

**Tip**: Click the help icon (2) next to the page title to open the embedded web copy of the *Keyfactor Command Reference Guide* to this section.

You can also find the help icon at the top of the page next to the **Log Out** button. From here you can choose to open either the *Keyfactor Command Documentation Suite* at the home page or the *Keyfactor API Endpoint Utility*.

# **Adding Server Groups**

To add a new server group:

- 1. In the Management Portal, browse to SSH > Server Manager.
- 2. On the Server Manager page, select the Server Groups tab (the default when you first visit the page).
- 3. On the Server Groups tab, click Add.

Figure 308: Add a Server Group

- 4. In the Add Server Group dialog, enter a name for the group in the Name field.
- 5. In the **Owner** dropdown, enter or select an Active Directory user with access to the Keyfactor Command Management Portal holding either the SSH Server Admin or SSH Enterprise Admin role (see <u>SSH Permissions on page 598</u>). Any users with one of these roles who have previously been made an owner on a server group or enrolled for an SSH key (see <u>My SSH Key on page 532</u>) will appear in the Owner dropdown.
- 6. In the **Schedule** dropdown, select a frequency for the server synchronization job. Possible options are:
  - Interval—Enter an interval from every 1 minute to every 12 hours
  - Daily—Enter selected time
  - Weekly-Enter a selected day or days of the week at a selected time
  - Monthly—Enter a selected day of the month (1st through 27th) at a selected time

**Tip:** During initial configuration, you may want to set a short timeframe for job frequency and then extend it as the servers settle into a management routine.

- 7. If desired, check the **Enforce Publish Policy** box to set the server group to *inventory and publish policy* mode (see SSH on page 526).
- 8. Click Save to save the new server group.

### **Editing or Deleting a Server Group**

To edit a server group, double-click the group, right-click the group and choose **Edit** from the right-click menu, or highlight the row in the server groups grid and click **Edit** at the top of the grid.

**Tip**: The owner can only be changed by a Keyfactor Command user who holds the *SSH Enter-* prise Admin role (see *SSH Permissions on page 598*).

To delete a server group, highlight the row in the server groups grid and click **Delete** at the top of the grid or right-click the group in the grid and choose **Delete** from the right-click menu.

### **Editing Access to an SSH Server Group**

Using the Edit Access function you create mappings between Keyfactor Command user accounts associated with SSH keys and Linux logons in order to publish the SSH public keys to all the Linux servers that belong to the selected server group (see <u>SSH on page 526</u>). You can also remove the mappings from here, which causes the SSH public keys to be removed from the Linux servers belonging to the selected server group.

Before adding a logon to user mapping, be sure that you have switched either the server group or all servers in the group to which you will add your mapping to *inventory and publish policy* mode (see <u>Server Manager on page 561</u>) so that the key for the user will be published to the servers in the group. If the servers in the server group are in *inventory only* mode and you add a mapping for it in Keyfactor Command, the mapping will appear in Keyfactor Command only and the key for the user will not be published out to the servers in the server group. If only some servers in the server group are in *inventory and publish policy* mode, the key for the user will only be published to those servers.

**Tip:** The time it will take for changes to access mappings to appear on your Linux servers will depend on the frequency of the server synchronization configured for the server group (see Adding Server Groups on page 562).

To edit the access for a server group, create a mapping between a Linux logon and a Keyfactor Command user, and publish the user's key to all the SSH servers belonging to that server group:

- 1. In the Management Portal, browse to SSH > Server Manager.
- 2. On the Server Manager page, select the Server groups tab.
- 3. In the Server groups grid, locate the server group that contains the servers you wish to publish an SSH key to by mapping a Keyfactor Command user to a Linux logon on that server group.
- 4. Right-click the server group and choose **Edit Access** from the right-click menu or highlight the row in the server groups grid and click **Edit Access** at the top of the grid.

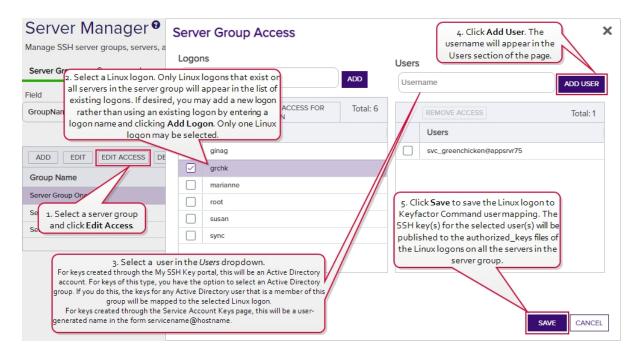

Figure 309: Edit Access for an SSH Server Group

5. On the Access Management page, select an existing Logon on the left side of the page. Logons only appear here if they exist with the same spelling on all servers in the server group. If you wish to add a new logon, enter the new logon name in the Logon field at the top of the left side of the page and click **Add Logon**. The new logon appears at the bottom of the Logon list. Click the **Logon** list title to sort the list, if desired. Select the new logon. Only one logon may be selected.

Tip: If you have enabled SSSD support for your Keyfactor Bash Orchestrator and are adding a domain user, specify the user in username@domain format. For example bbrown@keyexample.com (or, depending on SSSD configuration, such as the case-sensitivity setting; BBROWN@keyexample.com). Note that the logon may be modified by the SSSD configuration file in ways in which Keyfactor Command cannot know about. Refer to <a href="SSH-SSSD Case Sensitivity Flag on page 791">SSH-SSSD Case Sensitivity Flag on page 791</a> for guidance on what to enter based on how the SSSD case sensitivity flag is configured.

6. In the Users dropdown at the top of the right side of the page, select a user or service account to associate the logon with. Only Keyfactor users that have keys stored in Keyfactor Command, that have been designated as server group owners, or AD users or groups that have been previously entered for association with a logon will appear in the dropdown. If desired, you may enter an Active Directory user or group name in this field. Using an Active Directory group to create Linux logon to Keyfactor user mappings will cause the keys stored in Keyfactor Command for any Active Directory users that are members of this group to be mapped to the selected Linux logon and published to the servers on which the Linux logon exists. Any Active Directory users that are members of this group but who do not have keys stored in Keyfactor Command will not be

mapped to the selected Linux logon. Click Add User.

Tip: For keys created through the My SSH Key portal (see My SSH Key on page 532), a Keyfactor user is an Active Directory user account. For keys created through the Service Account Keys page (see Service Account Keys on page 543), a Keyfactor user is a usergenerated service account name of the form servicename@hostname.

- 7. Repeat step 6 for any other user or service accounts that you wish to map to this logon on the servers in this server group.
- 8. Click Save.

To remove a mapping of a Linux logon to a Keyfactor Command user for all the servers in a server group, remove the public key from the Linux logon's authorized\_keys files:

- 1. In the Management Portal, browse to SSH > Server Manager.
- 2. On the Server Manager page, select the Server Groups tab.
- 3. In the Server Groups grid, locate the server group that contains the servers you wish to remove an SSH key from by unmapping a Keyfactor Command user from a Linux logon on that server group.
- 4. Right-click the server group and choose Edit Access from the right-click menu or highlight the row in the server groups grid and click Edit Access at the top of the grid.

Figure 310: Edit Access for an SSH Server

- 5. On the Access Management page, select a Logon on the left side of the page. Only one logon may be selected.
- 6. In the Users section on the right side of the page, select a user or service account to unmap from the logon. Click Remove Access under Users. The Linux logon to Keyfactor user mapping for the selected user will be removed and the user's SSH key will be removed from the authorized\_keys files of the Linux logons on all the servers in the server group.

Tip: Clicking Remove Shared Access for Logon on the Logons side of the page removes all Linux logon to Keyfactor user mappings for the selected logon with one click without the need to select the users on the *Users* side of the page.

If a logon has user mappings on some servers and not others in the group (see the example, below), these will not appear in the Server Group Edit dialog, and none of these user mappings will be removed. The Remove Shared Access for Logon option only removes user mappings that are visible in the Server Group Access dialog.

This option does not delete the logon from any servers (see Editing or Deleting a Logon on page 589).

- 7. Repeat step 6 for any other user or service accounts that you wish to unmap from this logon on the servers in this server group.
- 8. Click Save.

Example: Server Group One contains three Linux servers-A, B and C. Linux logons for Anne, Betty and Dave exist on all three servers. A Linux logon for Chuck exists on servers A and B but not C. In Keyfactor Command:

- Anne has acquired an SSH key using My SSH Key (see My SSH Key on page 532) and an administrator has mapped it to her Linux logon for all three servers in Server Group One.
- Betty has acquired an SSH key using My SSH Key and an administrator has mapped it to her Linux logon account for servers A and B but not server C.
- Chuck has acquired an SSH key using My SSH Key and an administrator has mapped it to his Linux logon account for servers A and B. No Linux account exists for Chuck on server C and no user mapping has been done for Chuck for this server.
- Dave has acquired an SSH key using My SSH Key but it has not yet been mapped to his Linux logon account for any servers.

You can see these Linux logon to Keyfactor user mappings in Figure 311: Linux Logon to Keyfactor User Mappings for Anne, Betty, Chuck and Dave.

Figure 311: Linux Logon to Keyfactor User Mappings for Anne, Betty, Chuck and Dave

As a result of this logon setup and mapping configuration, when you open the Server Group Access dialog for *Server Group One* (see <u>Figure 312: Server Group Access Editing Example</u>), in the Logon column you will see *anne*, *betty* and *dave* but not *chuck*.

- Chuck is missing because he does not have a Linux logon account on server C.
- As you click on each of the users *anne*, *betty* and *dave* in the Logon column, on the right in the Users column, you will see that:
  - Anne's mapped user appears, but a mapped user does not appear for either Betty or Dave.
  - In Betty's case, this is because her Keyfactor user to Linux logon mapping does not exist for server C. Mapped users only appear if they are consistent across all Linux logons for a user.
  - In Dave's case, this is because he does not have a Keyfactor user to Linux logon mapping for any of the servers.
- Other shared Linux logons exist on the servers—such as root—that are not referenced in this example but are shown in Figure 312: Server Group Access Editing Example.

**Tip:** Logons only appear in the Linux logon column if they exist with the same spelling on all servers in the server group—dave does not equal david and will not be recognized as a Linux logon match.

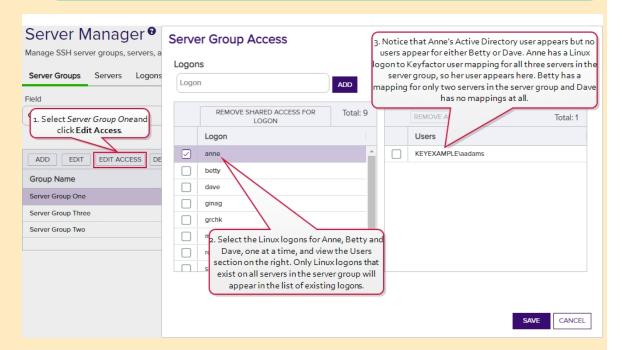

Figure 312: Server Group Access Editing Example

The administrator decides to do the following:

• On the Server Groups tab, she selects *Server Group One* and clicks **Edit Access** at the top of the grid.

- In the Server Group Access for *Server Group One*, she adds a Linux logon for *chuck* on the left and clicks **Save** without adding any user mappings on the right.
- Since *Chuck* already had Linux logon accounts on servers A and B, no changes are made on those servers. A Linux logon account is added on server C for *Chuck*.
- When the administrator opens the Server Group Access for Server Group One again, she
  sees Chuck's Linux logon on the left. When she clicks on chuck, no Users are shown on
  the right because Chuck only has Linux logon to Keyfactor user mappings for servers A
  and B, not for server C.

Figure 313: Concept: Add Linux Logon for Chuck on Server C

• In the Server Group Access for Server Group One, she selects chuck on the left and creates a mapping to Chuck's SSH key acquired through My SSH Key. This adds the key to the authorized\_keys file for Chuck on any servers in the server group that lack the key—in this case, server C. This then completes the mappings for Linux logon the Keyfactor user for Chuck for the servers in this server group. Chuck's user will then appear in the Server Group Access dialog when Chuck's Logon is selected.

Figure 314: Server Group Access: Add Linux Logon for Chuck on Server C

• In the Server Group Access for Server Group One, she selects betty on the left and creates a mapping to Betty's Active Directory account, which is associated with the SSH key acquired through My SSH Key, and to a service account key for Betty—svc\_grnch-k@appsrvr12 and clicks Save. Since Betty already had Linux logon to Keyfactor user mappings for servers A and B and her SSH key was already on these servers, no changes are made to these servers. Her key acquired through My SSH Key is published out to server C and added to her authorized\_keys file on that server. Betty had no previous mappings for the SSH service key svc\_grnchk@appsrvr12, so this key is published out to all three servers in the server group and added to her authorized\_keys files on those servers.

Figure 315: Add Logon to User Mapping for Betty

• At a later date, the administrator decides to remove Betty's access to the service account key. In the Server Group Access for Server Group One, she selects betty on the left and selects the service account key svc\_grnchk@appsrvr12 on the right. She clicks Remove Access and then Save. The SSH key for the svc\_grnchk@appsrvr12 service is removed from Betty's authorized\_keys file on servers A, B and C. When she opens the Server Group Access dialog again and selects Betty, she sees Betty's Active Directory account, associated with the SSH key acquired through My SSH Key, but not the svc\_grnchk@appsrvr12 service account.

Figure 316: Remove Logon to User Mapping for Betty

She decides to add Dave's key to the servers. On the Logons tab, she selects one of Dave's Linux logons on one of the servers in Server Group One and clicks Edit at the top of the grid. In the Edit Logon dialog, she changes to the Access Management tab, selects Dave's Active Directory account in the Users dropdown, and clicks Add User and Save. She repeats these steps for all the servers in Server Group One (servers A, B and C). Dave's SSH key acquired through My SSH Key is published out to all three servers in Server Group One and added to his authorized\_keys files on those servers.

Figure 317: Add Individual Logon to User Mappings for Dave

On the Server Groups tab, she selects Server Group One and clicks Edit Access at the
top of the grid. In the Server Group Access for Server Group One, she selects Dave's
Linux logon and sees that Dave's Active Directory account appears in the Users section
on the right when it did not previously. This is because she created Linux logon to
Keyfactor user mappings for Dave individually on the Logons tab for all the servers in
Server Group One. If she had only done this for some of the servers in Server Group One,
Dave's Active Directory user would not appear on the Server Group Access dialog.

## **Viewing Server Group Members**

To view the servers belonging to a server group, highlight the row in the server groups grid and click **View Group Members** at the top of the grid or right-click the group in the grid and choose **View Group Members** from the right-click menu. This will take you to the Servers tab with the advanced search populated by a query for the selected server group name.

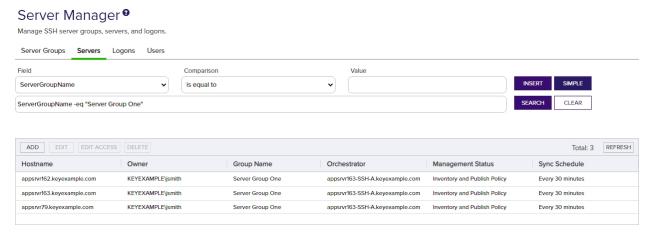

Figure 319: View Members of an SSH Server Group

### **Using the Server Group Search**

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an *is null* or *is not null* comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

Each query consists of three parts:

# **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

#### GroupName

Complete or partial matches with the server group name.

#### OwnerName

Complete or partial matches with the Active Directory username of the user who owns the server group. The owner can only be set by a Keyfactor Command user with the SSH Enterprise Admin role.

### **Enforce Publish Policy**

Server group is set to *enforce publish policy* yes/no.

**Tip:** If a specific server in a server group is not operating as expected from an inventory and policy publishing mode perspective, check the inventory and publish policy state of the individual server. The setting on the server overrides the setting on the server's group.

## **Comparison Operator**

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Contains (-contains)
- Does not contain (-notcontains)
- Most date and integer fields support:
- Is equal to (-eq)
- Is not equal to (-ne)

- Starts with (-startswith)
- Ends with (-endswith)
- Is null (-eq NULL)
- Is not null (-ne NULL)
- Is greater than (-gt)
- Is greater than or equal to (-ge)

- Is less than (-It)
- Is less than or equal to (-le)

- Is null (-eq NULL)
- Is not null (-ne NULL)

Most Boolean (true/false) fields support:

- Is equal to (-eq)
- Is not equal to (-ne)

- Is null (-eq NULL)
- Is not null (-ne NULL)

# **Comparison Value**

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

- Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.
- Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

### **Advanced Searches**

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

#### **Multiple Criteria**

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click **Insert** to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

In addition to the options available in the query builder, three special values can be used in selected searches by typing them in directly:

#### **SSH Servers**

On the Servers tab of the Server Manager page you enter records for all the SSH servers in the environment that will be inventoried or managed with the Keyfactor Bash Orchestrator. Each SSH server added here must have either the orchestrator installed on it or have had the remote install script for the orchestrator run on it, which sets up the machine for remote control by the orchestrator. For more information about the orchestrator, see Bash Orchestrator in the Keyfactor Orchestrators Installation and Configuration Guide.

You must create at least one server group before you can add SSH servers into the Keyfactor Command Management Portal (see SSH Server Groups on page 561).

Figure 320: SSH Servers Grid

Tip: Click the help icon (2) next to the page title to open the embedded web copy of the Keyfactor Command Reference Guide to this section.

You can also find the help icon at the top of the page next to the Log Out button. From here you can choose to open either the Keyfactor Command Documentation Suite at the home page or the Keyfactor API Endpoint Utility.

#### Adding SSH Servers

Before adding a new SSH server, be sure that you have added at least one server group (see Adding Server Groups on page 562) and that your Keyfactor Bash Orchestrator has been registered and approved in Keyfactor Command (see Orchestrator Management on page 497).

To add a new SSH server:

- 1. In the Management Portal, browse to SSH > Server Manager.
- 2. On the Server Manager page, select the Servers tab.
- 3. On the Servers tab, click Add.

Figure 321: Add an SSH Server

4. In the Add Server dialog on the Basic tab, enter the DNS hostname for the server in the **Host-name** field. This can be either the FQDN or a short name. An IP address may be used if desired. This field is required.

- 5. In the Orchestrator dropdown, select an approved orchestrator. This field is required.
- 6. In the Server Group dropdown, select an existing server group. This field is required.
- 7. In the **Port** field, either select the default SSH port of 22 or enter a custom port if an alternative port is used for SSH in your environment.
- 8. Select either the **Inventory Only** radio button or the **Inventory and Publish Policy** radio button (see SSH on page 526).

Tip: If the server group you selected above is configured in inventory and publish policy mode (with the Enforce Publish Policy box checked), you will not be able to save the server in inventory only mode.

9. Click Save to save the new server.

Tip: When you are first creating server records, you probably won't need to visit the Access Management tab of the server record. On this tab, you create mappings between Keyfactor Command user accounts associated with SSH keys and Linux logons in order to publish the SSH keys to the Linux servers (see SSH on page 526 and Editing or Deleting an SSH Server below).

### **Editing or Deleting an SSH Server**

To edit a server, double-click the server, right-click the server and choose Edit from the right-click menu, or highlight the row in the servers grid and click Edit at the top of the grid.

Only two of the fields are available for editing:

- Port Change the SSH port set for the server, if desired.
- · Management Status Select either the Inventory Only radio button or the Inventory and Publish Policy radio button.

Tip: If the server group for the server is configured in inventory and publish policy mode (with the Enforce Publish Policy box checked), you will not be able to save the server in inventory only mode.

To delete a server, highlight the row in the servers grid and click **Delete** at the top of the grid or right-click the server in the grid and choose **Delete** from the right-click menu.

Tip: The hostname, orchestrator, and server group for a server are not editable. If you wish to change one of these, delete the record and add a fresh record for the server.

#### Editing Access to an SSH Server

Using the Edit Access function you create mappings between Keyfactor Command user accounts associated with SSH keys and Linux logons in order to publish the SSH public keys to the Linux servers (see SSH on page 526). You can also remove the mappings from here, which causes the SSH public keys to be removed from the Linux servers.

Before adding a logon to user mapping, be sure that you have switched the server to which you will add your mapping (or its server group) to inventory and publish policy mode (see Server Manager on page 561) so that the key for the user will be published to the server. If the server is in *inventory only* mode and you add a mapping for it in Keyfactor Command, the mapping will appear in Keyfactor Command only and the key for the user will not be published out to the server.

To edit the access for a server, create a mapping between a Linux logon and a Keyfactor Command user, and publish the user's key to the SSH server:

- 1. In the Management Portal, browse to SSH > Server Manager.
- 2. On the Server Manager page, select the Servers tab.
- 3. In the Servers grid, locate the server that you wish to publish an SSH key to by mapping a Keyfactor Command user to a Linux logon on that server.
- 4. Right-click the server and choose **Edit Access** from the right-click menu or highlight the row in the servers grid and click **Edit Access** at the top of the grid.

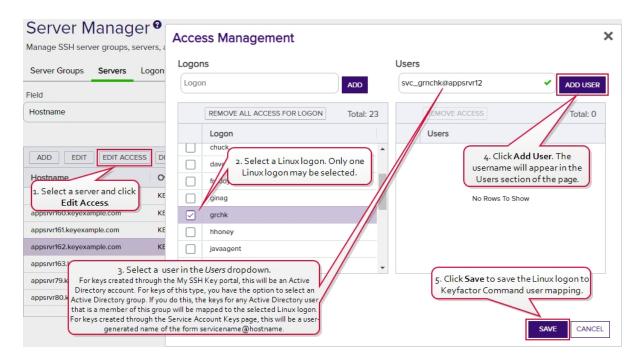

Figure 322: Edit Access for an SSH Server

5. On the Access Management page, select an existing Logon on the left side of the page. If you wish to add a new logon, enter the new logon name in the Logon field at the top of the left side of the page and click **Add Logon**. The new logon appears at the bottom of the Logon list. Click the **Logon** list title to sort the list, if desired. Select the new logon. Only one logon may be selected.

**Tip:** If you have enabled SSSD support for your Keyfactor Bash Orchestrator and are adding a domain user, specify the user in username@domain format. For example bbrown@keyexample.com (or, depending on SSSD configuration, such as the case-

sensitivity setting; BBROWN@keyexample.com). Note that the logon may be modified by the SSSD configuration file in ways in which Keyfactor Command cannot know about. Refer to SSH-SSSD Case Sensitivity Flag on page 791 for guidance on what to enter based on how the SSSD case sensitivity flag is configured.

6. In the Users dropdown at the top of the right side of the page, select a user or service account to associate the logon with. Only Keyfactor users that have keys stored in Keyfactor Command, that have been designated as server group owners, or AD users or groups that have been previously entered for association with a logon will appear in the dropdown. If desired, you may enter an Active Directory user or group name in this field. Using an Active Directory group to create Linux logon to Keyfactor user mappings will cause the keys stored in Keyfactor Command for any Active Directory users that are members of this group to be mapped to the selected Linux logon and published to the server on which the Linux logon exists. Any Active Directory users that are members of this group but who do not have keys stored in Keyfactor Command will not be mapped to the selected Linux logon. Click Add User.

Tip: For keys created through the My SSH Key portal (see My SSH Key on page 532), a Keyfactor user is an Active Directory user account. For keys created through the Service Account Keys page (see Service Account Keys on page 543), a Keyfactor user is a usergenerated service account name of the form servicename@hostname.

- 7. Repeat step 6 for any other user or service accounts that you wish to map to this logon on this server.
- 8. Click Save.

To remove a mapping of a Linux logon to a Keyfactor Command user for a server, removing the public key from the Linux logon's authorized\_keys file:

- 1. In the Management Portal, browse to SSH > Server Manager.
- 2. On the Server Manager page, select the Servers tab.
- 3. In the Servers grid, locate the server that you wish to remove an SSH key from by unmapping a Keyfactor Command user from a Linux logon on that server.
- 4. Right-click the server and choose Edit Access from the right-click menu or highlight the row in the servers grid and click Edit Access at the top of the grid.

Figure 323: Edit Access for an SSH Server

- 5. On the Access Management page, select a Logon on the left side of the page. Only one logon may be selected.
- 6. In the Users section on the right side of the page, select a user or service account to unmap from the logon. Click Remove Access under Users. The Linux logon to Keyfactor user mapping for the selected user will be removed and the user's SSH key will be removed from the authorized\_keys files of the Linux logon on the selected server.

**Tip:** Clicking **Remove All Access for Logon** on the *Logons* side of the page removes *all* Linux logon to Keyfactor user mappings for the selected logon on the selected server with one click without the need to select the users on the *Users* side of the page. This option does not delete the logon from any servers (see <u>Editing or Deleting a Logon on page 589</u>).

- 7. Repeat step 6 for any other user or service accounts that you wish to unmap from this logon on this server.
- 8. Click Save.

**Tip:** The time it will take for changes to access mappings to appear on your Linux server will depend on the frequency of the server synchronization configured for the server group to which the server belongs (see <u>Adding Server Groups on page 562</u>).

## **Using the SSH Server Search**

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an *is null* or *is not null* comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

Each query consists of three parts:

## **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

Hostname	EnforcePublishPolicy
Complete or partial matches with the hostname of the SSH server.	Server is in <i>inventory only</i> mode or <i>inventory and</i> publish policy mode.
ServerGroupName	ServerGroupOwner
Complete or partial matches with the name of the server group to which the SSH servers belong.	Complete or partial matches with the Active Directory username of the user who owns the server group to which the server belongs. The
Orchestrator	owner can only be set by a Keyfactor Command user with the SSH Enterprise Admin role.
Complete or partial matches with the orchestrator controlling the SSH servers.	user with the Soft Enterprise Admini role.

# **Comparison Operator**

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

• Is equal to (-eq)	<ul> <li>Starts with (-startswith)</li> </ul>
<ul> <li>Is not equal to (-ne)</li> </ul>	<ul> <li>Ends with (-endswith)</li> </ul>
<ul> <li>Contains (-contains)</li> </ul>	<ul> <li>Is null (-eq NULL)</li> </ul>
<ul> <li>Does not contain (-notcontains)</li> </ul>	<ul> <li>Is not null (-ne NULL)</li> </ul>
Most date and integer fields support:	
• Is equal to (-eq)	<ul> <li>Is greater than (-gt)</li> </ul>
• Is not equal to (-ne)	• Is greater than or equal to (-ge)

- Is less than (-It)
- Is less than or equal to (-le)

- Is null (-eq NULL)
- Is not null (-ne NULL)

Most Boolean (true/false) fields support:

- Is equal to (-eq)
- Is not equal to (-ne)

- Is null (-eq NULL)
- Is not null (-ne NULL)

## Comparison Value

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

- Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.
- Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

### **Advanced Searches**

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

#### **Multiple Criteria**

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click **Insert** to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

### Logons

On the Logons tab of the Server Manager page you can view all the Linux user accounts associated with authorized\_keys files containing valid SSH public keys. The logons shown here include both those discovered on SSH servers during the initial discovery phase using the orchestrator and those created in Keyfactor Command and published to the SSH servers using the orchestrator.

On this tab you can create new logons, see the number of keys associated with each logon, and create mappings between Keyfactor Command users and the logons in order to allow the orchestrator to publish new SSH keys for those users to the SSH servers (see SSH on page 526).

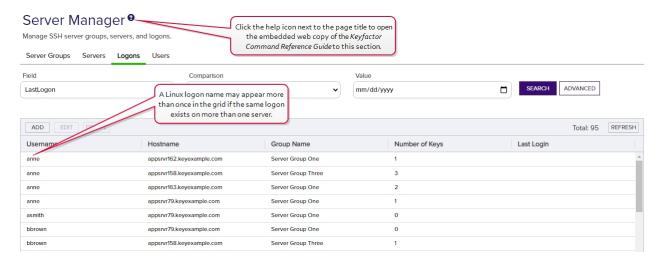

Figure 324: Linux Logons Grid

**Tip:** Click the help icon (2) next to the page title to open the embedded web copy of the *Keyfactor Command Reference Guide* to this section.

You can also find the help icon at the top of the page next to the **Log Out** button. From here you can choose to open either the *Keyfactor Command Documentation Suite* at the home page or the *Keyfactor API Endpoint Utility*.

### **Adding Logons**

Before adding a new logon, be sure that you have switched the server to which you will add your logon (or its server group) to *inventory and publish policy* mode (see <u>Server Manager on page 561</u>) so that the new logon will be published to the server. If the server is in *inventory only* mode and you add a new logon for it in Keyfactor Command, the logon will appear in Keyfactor Command only and will not be published out to the server.

**Tip:** New logons can also be added from the access management options for server groups and servers while creating Linux logon to Keyfactor Command user mappings (see Editing

# cess to an SSH Server Group on page 564 and Editing Access to an SSH Server on e 580).

To add a new logon:

- 1. In the Management Portal, browse to SSH > Server Manager.
- 2. On the Server Manager page, select the Logons tab.
- 3. On the Logons tab, click Add.

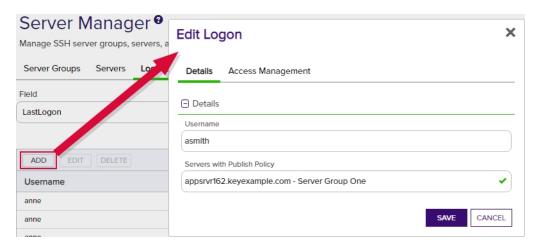

Figure 325: Add a Linux Logon—Basic Tab

4. In the Add Logon dialog on the Details tab, enter a Linux Username for the user.

Tip: If you have enabled SSSD support for your Keyfactor Bash Orchestrator and are adding a domain user, specify the user in username@domain format. For example bbrown@keyexample.com (or, depending on SSSD configuration, such as the case-sensitivity setting; BBROWN@keyexample.com). Note that the logon may be modified by the SSSD configuration file in ways in which Keyfactor Command cannot know about. Refer to SSH-SSSD Case Sensitivity Flag on page 791 for guidance on what to enter based on how the SSSD case sensitivity flag is configured.

- 5. In the Servers with Publish Policy dropdown on the Details tab, select an available SSH server on which to create the logon. Only servers that are configured in inventory and publish policy mode (see Server Manager on page 561) will appear in this dropdown. This field is required.
- 6. On the Access Management tab in the Users & Groups with Login Access dropdown, select a user or service account to associate the logon with. Only accounts that have keys stored in Keyfactor Command or that have been designated as server group owners will appear in the dropdown. If desired, you may enter an Active Directory group name in this field. This will cause the keys stored in Keyfactor Command for any Active Directory users that are members of this

group to be mapped to the selected Linux logon and published to the server on which the Linux logon exists. Any Active Directory users that are members of this group but who do not have keys stored in Keyfactor Command will not be mapped to the selected Linux logon. Click Add. The Access Management tab is optional.

Tip: For keys created through the My SSH Key portal (see My SSH Key on page 532), a Keyfactor user is an Active Directory user account. For keys created through the Service Account Keys page (see Service Account Keys on page 543), a Keyfactor user is a usergenerated service account name of the form servicename@hostname.

Figure 326: Add a Linux Logon—Access Management Tab

7. Click **Save** to save the new logon.

Note: When the logon is created on the Linux server, a home directory will be created for it and within this, the .ssh directory and authorized\_keys file. The logon user will be made owner of the home directory and granted rwx permissions to it. No password is set for the user and as initially configured, the user will not be able to remotely login.

Tip: The time it will take for new logons to appear on your Linux server will depend on the frequency of the server synchronization configured for the server group to which the server belongs (see Adding Server Groups on page 562).

### **Editing or Deleting a Logon**

On the Access Management tab of the Edit Logon dialog, you can map Keyfactor user accounts to Linux logon account to cause the SSH keys in Keyfactor Command associated with thoseKeyfactor users to be published to the authorized\_keys file of the Linux user (see SSH on page 526).

To map an Keyfactor Command user to a Linux logon:

- 1. In the Management Portal, browse to *SSH* > *Server Manager*.
- 2. On the Server Manager page, select the Logons tab.
- 3. In the Logons grid locate the logon that you wish to publish an SSH key to by mapping an Active Directory account to it. Be sure to select the logon associated with the correct server, as the same logon name may appear for multiple servers.
- 4. Double-click the logon, right-click the logon and choose **Edit** from the right-click menu, or high-light the row in the logons grid and click **Edit** at the top of the grid.
- 5. On the Access Management tab in the Users & Groups with Login Access dropdown, select a user or service account to associate the logon with. Only Keyfactor users that have keys stored in Keyfactor Command, that have been designated as server group owners, or AD users or groups that have been previously entered for association with a logon will appear in the dropdown. If desired, you may enter an Active Directory user or group name in this field. Using an Active Directory group to create Linux logon to Keyfactor user mappings will cause the keys stored in Keyfactor Command for any Active Directory users that are members of this group to be mapped to the selected Linux logon and published to the server on which the Linux logon exists. Any Active Directory users that are members of this group but who do not have keys stored in Keyfactor Command will not be mapped to the selected Linux logon. Click Add.

**Tip:** For keys created through the My SSH Key portal (see My SSH Key on page 532), a Keyfactor user is an Active Directory user account. For keys created through the Service Account Keys page (see Service Account Keys on page 543), a Keyfactor user is a usergenerated service account name of the form servicename@hostname.

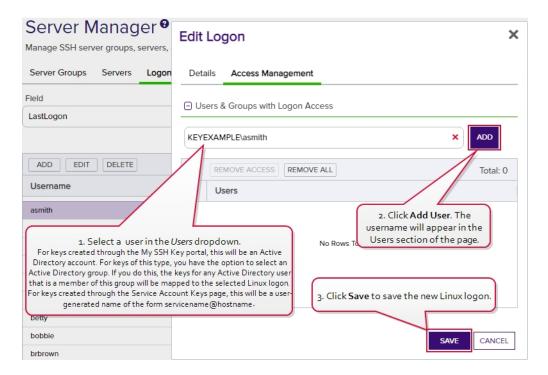

Figure 327: Edit Access for a Linux Logon

6. Click **Save** to save the access management settings.

**Tip:** Only the mappings of Keyfactor users to Linux logons on the Access Management tab are editable in an existing logon record. Nothing on the Details tab of the Edit Logon dialog is editable.

**Note**: If you opt to create Linux logon to Keyfactor user mapping using Active Directory groups, be aware that the key count values shown on the Logons grid will not reflect the keys associated with the members of the groups.

To delete a logon, highlight the row in the logons grid and click **Delete** at the top of the grid or rightclick the logon in the grid and choose **Delete** from the right-click menu.

**Note**: Deleting a logon in Keyfactor Command does not delete it on the Linux server. It must be manually removed from the Linux server at the same time. If this is not done, when the next inventory of the Linux server is performed, the logon will be recreated in Keyfactor Command. This function is intended primarily to be used to clean up logons from SSH servers that have been retired.

#### **Using the Logons Search**

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an *is null* or *is not null* comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

Each query consists of three parts:

### **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

Username	Hostname
Complete or partial matches with the Linux logon	Complete or partial matches with the hostname of

name of the user account on the SSH server.	the SSH server on which the logon resides.

LastLogon	UnmanagedKevId

The date on which the logon was last used to login to the given hostname.

The Keyfactor Command reference ID of the unmanaged key(s) associated with the logon.

## **Comparison Operator**

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

•	Is equal to (-eq)	•	Starts with (-startswith)
•	Is not equal to (-ne)	•	Ends with (-endswith)

- Contains (-contains) Is null (-eq NULL)
- Does not contain (-notcontains)
   Is not null (-ne NULL)

Most date and integer fields support:

- Is equal to (-eq)
   Is greater than (-gt)
- Is not equal to (-ne)
   Is greater than or equal to (-ge)
- Is less than (-it)
   Is null (-eq NULL)
   Is less than or equal to (-ie)
   Is not null (-ne NULL)

Most Boolean (true/false) fields support:

Is equal to (-eq)
Is null (-eq NULL)
Is not equal to (-ne)
Is not null (-ne NULL)

# **Comparison Value**

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

- Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.
- Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

#### **Advanced Searches**

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

### **Multiple Criteria**

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click **Insert** to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

In addition to the options available in the query builder, three special values can be used in selected searches by typing them in directly:

- %TODAY%
  - Use the TODAY special value in place of a specific date in date queries. This option supports math operations, so you can use TODAY-10 or TODAY+30. The built-in *Certificates Expiring in 7 Days* collection uses this special value (see Certificate Collection Manager on page 85).
- %ME%
   Use the ME special value in place of a specific domain\user name in queries that match a domain\user name. The built-in My Certificates collection uses this special value (see Certificate Collection Manager on page 85).
- %ME-AN%
  - Use the ME-AN special value in place of a specific user name excluding the domain. This is beneficial in environments with multiple domains where there is a desire to query for a user's certificates even if they were requested across multiple domains.

**Important**: The special query options of %TODAY%, %ME%, and %ME-AN% are only supported in uppercase. Lowercase equivalents (e.g. %me%) cannot be substituted.

#### **SSH Users**

On the Users tab of the Server Manager page you can view all the SSH users defined in Keyfactor Command. Both users and service accounts are included. See SSH on page 526 for more

information on the difference between users and service accounts. Active Directory groups may also be included if they have previously been used to create Linux logon to Keyfactor user mappings (see Editing Access to an SSH Server on page 580). Groups appear without associated keys (since keys are associated with the member users, not the groups). Users may appear here without associated keys if the user account has been used to grant ownership on a server group but the user has not requested an SSH key pair.

On this tab you can see the keys associated with each user and create mappings between the users and Linux logons in order to allow the orchestrator to publish new SSH keys for those users to the SSH servers associated with the selected Linux logons (see SSH on page 526).

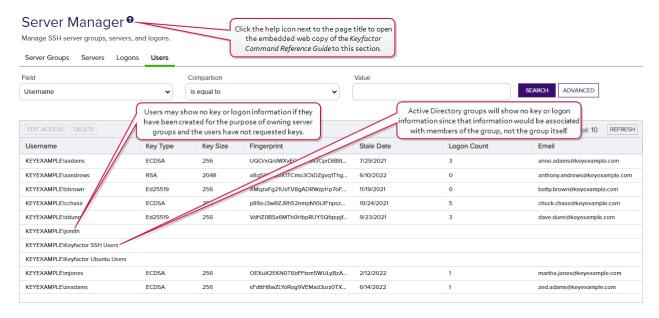

Figure 329: SSH Users Grid

### Editing or Deleting an SSH User

On the Details tab of the Edit User dialog, you can view details about the user and associated key. On the Access Management tab of the Edit User dialog, you can map Keyfactor user accounts to Linux logon account to cause the SSH keys in Keyfactor Command associated with those Keyfactor users to be published to the authorized\_keys file of the Linux user (see SSH on page 526).

**Tip:** For keys created through the My SSH Key portal (see My SSH Key on page 532), a Keyfactor user is an Active Directory user account. For keys created through the Service Account Keys page (see Service Account Keys on page 543), a Keyfactor user is a usergenerated service account name of the form servicename@hostname.

To map an Keyfactor user to a Linux logon:

- 1. In the Management Portal, browse to *SSH* > *Server Manager*.
- 2. On the Server Manager page, select the Users tab.

- 3. In the Users grid locate the user whose key you wish to publish to one or more Linux logons.
- 4. Double-click the user, right-click the user and choose **Edit Access** from the right-click menu, or highlight the row in the users grid and click **Edit Access** at the top of the grid.
- On the Access Management tab in the Login Access dropdown, select a logon to associate the
  user or service account with. A logon will appear more than once if it exists on more than one
  server. Be sure to select the logon on the correct server. Click Add.

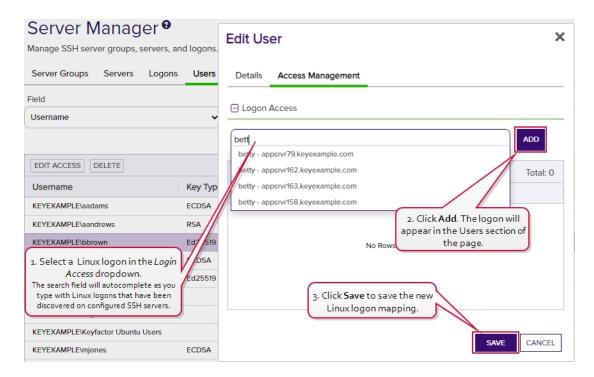

Figure 330: Edit Access for a Keyfactor User

6. Click **Save** to save the access management settings.

**Tip:** Only the mappings of Keyfactor users to Linux logons on the Access Management tab are editable in an existing user record. Nothing on the Details tab of the Edit Users dialog is editable.

To delete a user, highlight the row in the users grid and click **Delete** at the top of the grid or right-click the user in the grid and choose **Delete** from the right-click menu.

# Using the SSH Users Search

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an *is null* or *is not null* comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

Each query consists of three parts:

## **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

#### Username

Complete or partial matches with the username of the user. Keyfactor users (based on Active Directory users), Active Directory groups, and service accounts are included in the grid. For Active Directory users and groups, the username is in the form DOMAIN\username. For service accounts, the username is made up of the username and client hostname entered when the service account key was created (e.g. myapp@appsrvr75). Supports the %ME% token (see Advanced Searches on the next page).

#### KeyType

A number of cryptographic algorithms can be used to generate SSH keys. Keyfactor Command supports RSA, Ed25519, and ECDSA. RSA keys are more universally supported, and this is the default key type when generating a new key.

#### KeyLength

The key size available when generating a new key depends on the key type selected. Keyfactor Command supports 256 bits for Ed25519 and ECDSA and 2048 or 4096 bits for RSA. The default key length is 2048.

#### Fingerprint

The fingerprint of the public key. Each SSH public key has a single cryptographic fingerprint that can be used to uniquely identify the key.

#### Email

The email address of the user requesting the key. This email address is used to alert the user when the key pair is approaching the end of its lifetime (see Key Rotation Alerts on page 203).

#### StaleDate

The date on which the SSH key pair is considered to have reached the end of its lifetime. By default, the lifetime of an SSH key pair is 365 days (see Application Settings: SSH Tab on page 621). Supports the %TODAY% token (see Advanced Searches on the next page).

#### LogonCount

The number of Linux logons associated with the user.

## **Comparison Operator**

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Contains (-contains)
- Does not contain (-notcontains)

### Most date and integer fields support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Is less than (-It)
- Is less than or equal to (-le)

## Most Boolean (true/false) fields support:

- Is equal to (-eq)
- Is not equal to (-ne)

- Starts with (-startswith)
- Ends with (-endswith)
- Is null (-eq NULL)
- Is not null (-ne NULL)
- Is greater than (-gt)
- Is greater than or equal to (-ge)
- Is null (-eq NULL)
- Is not null (-ne NULL)
- Is null (-eq NULL)
- Is not null (-ne NULL)

## Comparison Value

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

- Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.
- Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

## **Advanced Searches**

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

#### **Multiple Criteria**

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click **Insert** to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

- %TODAY%
  - Use the TODAY special value in place of a specific date in date queries. This option supports math operations, so you can use TODAY-10 or TODAY+30. The built-in *Certificates Expiring in 7 Days* collection uses this special value (see Certificate Collection Manager on page 85).
- %ME%
   Use the ME special value in place of a specific domain\user name in queries that match a domain\user name. The built-in My Certificates collection uses this special value (see Certificate Collection Manager on page 85).
- %ME-AN%
   Use the ME-AN special value in place of a specific user name excluding the domain. This is beneficial in environments with multiple domains where there is a desire to query for a user's certificates even if they were requested across multiple domains.

**Important**: The special query options of %TODAY%, %ME%, and %ME-AN% are only supported in uppercase. Lowercase equivalents (e.g. %me%) cannot be substituted.

#### 2.1.10.5 SSH Permissions

Permissions to use the SSH areas of Keyfactor Command are controlled with three security roles specific to this purpose:

- Enterprise Admin
- Server Admin
- User

Most functions in the Management Portal are available to users with the Server Admin role for SSH. The Enterprise Admin role is used to grant administrators the permission to create server groups and change the owner of a server group (see <u>SSH Server Groups on page 561</u>). Other than these two things, users with the Server Admin role and those with the Enterprise Admin role have the same level of access. Users with the User role (and neither of the SSH admin roles) can access only the My SSH Key page to allow them to generate an SSH key pair for their own use.

**Tip:** Permissions for the SSH reports and the key rotation alerts (see <u>Key Rotation Alerts on page 203</u>) are covered by the standard reporting and workflow permission roles, not by the specialized SSH permission roles.

<u>Table 17: SSH Permissions Table</u> shows the access users with each of these roles has to the SSH functions within the Management Portal.

Table 17: SSH Permissions Table

Action	SSH Enterprise Admin	SSH Server Admin	SSH User
User Key: Generate and Rotate (My SSH Key)	Yes	Yes	Yes
User Key: Download (My SSH Key)	Yes	Yes	Yes
Service Account Key: View and Search for Service Account Keys	Yes	Limited <sup>1</sup>	No
Service Account Key: Add	Yes	Limited <sup>2</sup>	No
Service Account Key: Edit	Yes	Limited <sup>3</sup>	No
Service Account Key: Delete	Yes	Limited <sup>4</sup>	No
Service Account Key: Download	Yes	Limited <sup>5</sup>	No
Unmanaged Keys: View and Search for Unmanaged Keys	Yes	Yes <sup>6</sup>	No
Unmanaged Keys: Delete	Yes	Yes <sup>7</sup>	No
Server Group: View and Search for Server Groups	Yes	Limited <sup>8</sup>	No
Server Group: Add	Yes	No	No
Server Group: Edit	Yes	Limited <sup>9</sup>	No

<sup>1</sup>Users with the Server Admin role may only view and search for service account keys that are in server groups they own.

<sup>&</sup>lt;sup>2</sup>Users with the Server Admin role may only create service account keys in server groups they own.

<sup>&</sup>lt;sup>3</sup>Users with the Server Admin role may only view and edit service account keys that are in server groups they own.

<sup>&</sup>lt;sup>4</sup>Users with the Server Admin role may only view and delete service account keys that are in server groups they own.

<sup>&</sup>lt;sup>5</sup>Users with the Server Admin role may only view and download service account keys that are in server groups they own.

<sup>&</sup>lt;sup>6</sup>Users with the Server Admin role may only view and delete unmanaged keys that are in server groups they own.

<sup>&</sup>lt;sup>7</sup>Users with the Server Admin role may only view and delete unmanaged keys that are in server groups they own.

<sup>&</sup>lt;sup>8</sup>Users with the Server Admin role may only view and search for server groups they own.

<sup>&</sup>lt;sup>9</sup>Only users with the Enterprise Admin role may change the owner of a server group. Users with the Server Admin role may change other settings when editing a server group.

Action	SSH Enterprise Admin	SSH Server Admin	SSH User
Server Group: Delete	Yes	No	No
Server Group: View Members of a Server Group	Yes	Limited <sup>1</sup>	No

# 2.1.11 System Settings

System Settings are accessed via the settings icon 🌣 at the top right of the Management Portal.

Figure 331: System Settings Icon

The options available in the System Settings section of the Management Portal are:

## **Application Settings**

View or modify settings that control the Keyfactor Command applications.

## Security Roles and Identities

Configure security roles to provide customized

# **Event Handler Registration**

Configure built-in or custom event handlers.

## **Privileged Access Management**

Configure PAM providers for use of Privileged Access Management (PAM) to secure certificate

<sup>&</sup>lt;sup>1</sup>Users with the Server Admin role may only view and edit logons that are on servers in server groups they own.

<sup>&</sup>lt;sup>2</sup>Users with the Server Admin role may only map SSH keys from user accounts to Linux logons on servers that are in server groups they own.

<sup>&</sup>lt;sup>3</sup>Users with the Server Admin role may only view and delete logons that are on servers in server groups they own.

<sup>&</sup>lt;sup>4</sup>Users with the Server Admin role may only view and search for users that are associated with logons that are in server groups they own.

<sup>&</sup>lt;sup>5</sup>Users with the Server Admin role may only map SSH keys from user accounts to Linux logons on servers that are members of server groups that they own.

<sup>&</sup>lt;sup>6</sup>Users with the Server Admin role may only view and delete users that are associated with logons that are in server groups they own.

levels of access to the Management Portal, configure users and/or groups and grant them access to the roles.

## **Certificate Store Types**

Configure the types of certificate stores available for inventory, management, discovery, and reenrollment operations. This facilitates the creation of custom orchestrators to perform tasks against a wider set of certificate locations.

#### **Certificate Metadata**

Create custom metadata fields that can be used to capture additional data about certificates and report or alert based on it.

#### **Audit Log**

Display activity (e.g. creation, change, deletion) that has triggered an audit flag on a record in Keyfactor Command affecting an auditable area (e.g. Certificates, Security, Templates, Application Settings).

#### stores.

## **SMTP Configuration**

Configure email.

## **Component Installations**

View the servers on which Keyfactor Command server software is installed and the components installed on those servers.

## Licensing

View or change your Keyfactor Command license.

## 2.1.11.1 Application Settings

Many of the settings that control the behavior of Keyfactor Command features are configurable from the **Applications Settings** on the System setting menu. Browse to *System Settings Icon* > *Application Settings*. The tables below provide a brief description of these settings.

Each tab of the Applications Settings page is organized into sections—a **General** section and additional sections based on the functionality controlled by each tab. Click the plus  $(\pm \sqrt{-})$  next to a section to toggle expand/collapse that section.

Depending on your Keyfactor Command license, not all application settings may be applicable in your environment.

# **Application Settings: Console Tab**

# Application Settings 9

Figure 332: Console Application Settings: General

# Application Settings 9

Console	Auditing	Enrollment	Agents	API	SSH	Workflow

Pending Ale	t Test Result L	.imit			10	00	
SAVE U	NDO ALL						

Figure 333: Console Application Settings: Monitoring

Table 18: Console Application Settings

Tab	Section	Field	Description
Console	General	Bulk Edit Details Batch Size	The number of certificates at a time that are read from the database when using the Edit All feature to edit certificate metadata. This setting can be adjusted if there are responsiveness issues when editing large numbers of certificates at once. The default value is 5000.
Console	General	Bulk Edit Batch Size	The number of certificates at a time that are saved to the database when using the Edit All feature to edit certificate metadata. This setting can be adjusted if there are responsiveness issues when editing large numbers of certificates at once. The default value is 3000.
Console	General	CA Sync Consec- utive Error Limit	The number of errors a CA synchronization can encounter before the synchronization job stops (without running to completion).
Console	General	CA Sync Back- ward Offset	The number of minutes to offset when determining whether a certificate requested outside of

Tab	Section	Field	Description
		Minutes	Keyfactor Command should be included in an incremental synchronization. Adjusting this value can be helpful in situations of extreme clock skew or when the EJBCA <i>Validity Offset</i> setting is enabled.
			Note: For EJBCA CAs, if the certificate profile has a Validity Offset configured to a value greater than the value configured in the CA Sync Backward Offset Minutes application setting (15 minutes by default), certificates requested outside of Keyfactor Command will not be picked up on incremental scans. These certificates will only appear in Keyfactor Command on a full synchronization. The CA Sync Backward Offset Minutes application setting should be set to the same number of minutes as the Validity Offset value, if Validity Offset is configured.  Validity Offset[?]  Use  -30m  ("y "mo "d "h "m "s) - y = 365 days, mo = 30 days  Figure 334: EJBCA Certificate Profile Validity Offset Greater than 15 Minutes
Console	General	CA Sync Page Size	The number of records at a time that are read from the CA during a CA synchronization job. The default value is 500.
			Note: This setting applies only to EJBCA CAs.
Console	General	Dashboard Collection Caching Interval (minutes)	The number of minutes before data for the Collections dashboard panel is refreshed. The default value is 20.
Console	General	Weeks of CA Stats	The number of weeks of CA data to include in the dashboard graphs. The default value is 24.
Console	General	Debug Embedded	If set to <b>True</b> , causes an <i>Enable Debug</i> tickbox to

Tab	Section	Field	Description
		Reports	appear on the parameters page for reports you access and run from the Navigator (reports on the Reports menu dropdown of the Management Portal). This option does not appear for reports generated from the Report Manager grid. When enabled it allows the reports to output debug level information when they run. If set to False, does not display the Enable Debug option. The default value is False.  Tip: When the debugging option is enabled, a small debug icon (*) appears at the bottom of reports that generate successfully. You can click on it to see information about the report.
			about the report.
Console	General	Display CA Host- name	If set to <b>True</b> , causes both the CA's FQDN and logical name (e.g. ca2.keyexample.com\Corp Issuing CA Two) to display in the CA fields on the Certificate Authority, Certificate Requests and API Applications pages of the Management Portal. If set to <b>False</b> , only the CA's logical name (e.g. Corp Issuing CA Two) displays on these pages. The default value is True.
Console	General	Extension Handler Path	The path to the location on the Keyfactor Command server where the event handler .dll files are stored. By default this is:  C:\Program Files\Keyfactor\Keyfactor
			Platform\ExtensionLibrary\.
Console	General	Identity Provider Hint	A string that sets the default federated identity provider for all logins. When configured, the Keyfactor Identity Provider will be bypassed and all users will be directed to the login page of the federated identity provider specified by this hint. For more information, see Federating from Keyfactor Identity Provider in the Keyfactor Command Server Installation Guide.
Console	General	Immediately	If set to <b>True</b> , causes certificates to immediately

Tab	Section	Field	Description
		Sync Revoked Certificates	sync to Keyfactor Command upon revocation rather than waiting for the next scheduled synchronization cycle. The default value is True.
Console	General	Report Footer	A string that appears at the bottom of Logi-based reports either generated from the Management Portal or generated with the Report Manager in PDF format. The report footer appears only at the very end of the report, not at the foot of every page in the report.
Console	General	Report Footer Icon	The file name of an image to be used at the bottom of each page of exported and scheduled PDF reports. You can use this to replace the Keyfactor logo with a custom image on your reports. The image is auto set to a height of 30px. This image should be placed in the _SupportFiles folder under the Logi folder (located at C:\Program Files\Keyfactor\Keyfactor Platform\Logi by default).
Console	General	Revoke All Enabled	If set to <b>True</b> , causes the Revoke All button to appear at the top of certificate search and collection grids to allow users with appropriate permissions to revoke all certificates shown in the grid or included in the certificate collection. If set to <b>False</b> , hides the Revoke All button and disables the POST /Certificates/RevokeAll API endpoint. The default value is False for new installations of Keyfactor Command beginning with release 10.4.
Console	General	Timer Service Configuration Interval (minutes)	The number of minutes between checks by the master scheduling service for changes to the synchronization schedules. Any changes made to this value will not be applied until the Keyfactor Command service is restarted. The default value is 10.
Console	General	Lock Timeout (seconds)	The amount of time to attempt to acquire a lock ensuring that only one timer service job runs at a time across multiple servers. Default is 5 seconds.
Console	General	Lock Heartbeat Interval	How often to update the lock to keep it alive while running a long running timer service job. Default is

Tab	Section	Field	Description
		(seconds)	60 seconds.
Console	General	Lock Hold Timeout (seconds)	How long to wait after the last successful heartbeat interval before the lock is considered to be lost and can be acquired by another machine. Default is 900 seconds.
Console	Monitoring	Expiration Alert Test Result Limit	The maximum number of expiration alert emails that will be sent when an expiration alert test is run from within the Management Portal. If the number set here is exceeded during a test, emails will not be sent, but a portion of the alerts will be visible on the expiration alerts test page (see <a href="Testing Expiration Alerts on page 172">Testing Expiration Alerts on page 172</a> ). The default value is 100.
Console	Monitoring	Key Rotation Alert Test Result Limit	The maximum number of key rotation alert emails that will be sent when a key rotation alert test is run from within the Management Portal. If the number set here is exceeded during a test, emails will not be sent, but a portion of the alerts will be visible on the key rotation alerts test page (see <a href="Testing Key Rotation Alerts on page 207">Testing Key Rotation Alerts on page 207</a> ). The default value is 100.
Console	Monitoring	Pending Alert Test Result Limit	The maximum number of pending alert emails that will be sent when a pending alert test is run from within the Management Portal. If the number set here is exceeded during a test, emails will not be sent, but a portion of the alerts will be visible on the pending alerts test page (see <a href="Testing Pending Request Alerts on page 184">Testing Pending Request Alerts on page 184</a> ). The default value is 100.
Console	Monitoring	Pending Alerts Max Reminders	The maximum number of pending alert emails that will be sent for a given pending certificate. Every time a pending alert task is run, an email will be sent for a given pending certificate until the limit is reached. It is recommended that the number is kept at 5 or less. The default value is 1.

# **Application Settings: Auditing Tab**

# Application Settings 9

Figure 335: Audit Log Application Settings

Table 19: Audit Log Application Settings

Tab	Section	Field	Description
Auditing	General	Audit Entry Retention	The number of years to retain the audit log entry details. The default value is 7.
		Period	Note: The audit log cleanup job runs once daily and removes any audit log entries older than the time specified in the retention parameter except those in the following protected categories:  • Security  • CertificateCollections  • ApplicationSettings  • SecurityIdentities  • SecurityRoles  Audit logs belonging to protected categories

Tab	Section	Field	Description
			are retained indefinitely and cannot be deleted.  To retain all audit log entries indefinitely, disable the job. See <a href="Keyfactor Command-Service Job Settings">Keyfactor Command-Service Job Settings on page 778</a> .
Auditing	Log Server	Host Name	The host name of the centralized logging server to receive the Keyfactor Command audit log entries.
Auditing	Log Server	Port	The port to connect to the centralized logging server. The default port (configurable during install) is 514.
Auditing	Log Server	Use SysLog Server	If set to <b>True</b> , enables sending audit log details to a centralized logging server. See Audit Log Output to a Centralized Logging Solution on page 805.
Auditing	Log Server	Use TLS Connection	If set to <b>True</b> , enables sending audit log details to a centralized logging server over a TLS connection. See Audit Log Output to a Centralized Logging Solution on page 805.

# **Application Settings: Enrollment Tab**

**Note:** Regular expressions for enrollment that were previously configured under application settings are now configured on the templates page (see Regular Expressions on page 403).

Figure 336: Enrollment Application Settings

Table 20: Enrollment Application Settings

Tab	Section	Field	Description
Enrollment	General	Display CA Hostname	If set to <b>True</b> , causes both the CA's FQDN and logical name (e.g. ca2.keyexample.com\Corp Issuing CA Two) to display in the CA dropdowns in the Keyfactor Command Management Portal interfaces. If set to <b>False</b> , only the CA's logical name (e.g. Corp Issuing CA Two) displays in these dropdowns. The default value is True.
Enrollment	nrollment General	Subject Format	The format of the subject field that will be created for the certificates requested through the Keyfactor Command Management Portal if the template used for enrollment is set to supply in request. For example:  CN={CN},E={E},O=Key Example Inc.,OU={OU},L=Chicago,ST=IL,C=US
			The data in the subject format takes precedence over any data entered during PFX enrollment or supplied by enrollment defaults (see <a href="Enrollment Defaults Tab">Enrollment Defaults Tab</a> on page 399). For example, with the above subject format, the organization for certificates generated through PFX enrollment will always be *Key Example, Inc.* regardless of what is shown on the PFX enrollment page during enrollment.  This setting applies to CSRs generated using the CSR generation method in the Keyfactor Command Management Portal and CSR and PFX enrollments done in the Keyfactor Command Management Portal.  Data from the default subject *does not* display on the CSR or PFX enrollment page. To define defaults that will display in the PFX enrollment form (and can be modified by users), use enrollment defaults (see <a href="Enrollment Defaults Tab on page 399">Enrollment Defaults Tab on page 399</a> ).  Note: Backslashes are required before any commas embedded within values in the subject field (e.g. O=Key Example Inc.).  Quotation marks should not be used in the strings in the fields except in the case where these are part of the desired subject value, as

Tab	Section	Field	Description
			they are processed as literal values.
			Tip: The default subject format does not apply to enrollments done using the Keyfactor API.
Enrollment	General	URL to Subscriber Terms	The URL for a web page providing terms and conditions to which a user must agree before being allowed to enroll for a certificate if the CA setting of Require Subscriber Terms is enabled.
Enrollment	CSR	Allow CSR SAN Entry	If set to <b>True</b> , enables the section of the CSR enrollment page that allows for entry of custom subject alternative names (SANs). The default value is False.
Enrollment	CSR	Enabled	If set to <b>True</b> , enables administrative CSR enrollment. The default value is True.
Enrollment	PFX	Allow Custom Friendly Name	If set to <b>True</b> , enables the section of the PFX enrollment page that allows for entry of a custom friendly name for the certificate. The default value is False.
Enrollment	PFX	Allow Custom Password	If set to <b>True</b> , enables the section of the PFX enrollment page that allows for entry of a custom password for the PFX file. The default value is False.
Enrollment	PFX	Enabled	If set to <b>True</b> , enables administrative PFX enrollment. The default value is True.
Enrollment	PFX	File Extension	The file extension that will be given to the certificate files. Typical extensions are PFX or P12. The default value is PFX.
Enrollment	PFX	Only use Alpha Numeric Chars	If set to <b>True</b> , the one-time password generated to encrypt the PFX file acquired through the Keyfactor Command Management Portal (if the user's Active Directory password is not used) will contain just numbers and letters. If set to <b>False</b> , the password will contain numbers, letters and special characters. This setting is ignored if PFX Use Active Directory Password is set to <b>True</b> . The default value is True.

Tab	Section	Field	Description
Enrollment	Enrollment PFX Use Active Directory Password	Directory	If set to <b>True</b> , uses the user's Active Directory password to encrypt the PFX file containing the certificate acquired through the Keyfactor Command Management Portal and its private key. If set to <b>False</b> , generates a one-time password to encrypt the PFX file. The default value is False.
		Important: If you change this setting in the application settings you must also change the authentication method configured on the IIS virtual application <i>KeyfactorPortal</i> through the IIS Manager. If you set this option to <i>True</i> , you should configure only Basic Authentication in IIS. If you set this option to <i>False</i> , you may configure either only Windows Authentication or both Basic Authentication and Windows Authentication (the default) in IIS. This is because when you authenticate to the Management Portal using integrated Windows authentication (Kerberos), Keyfactor Command does not have access to your credentials to apply your password to the PFX file.	
Enrollment	PFX	Password Length	The number of characters in the one-time auto-generated password, or the required number of characters in the custom password, to encrypt the PFX file acquired through the Keyfactor Command Management Portal The minimum number is 8. The default value is 12. This value will be displayed on the PFX enrollment page - password section (if <u>Allow Custom Password on the previous page</u> is set to true).
			Important: Keyfactor highly recommends that you use strong passwords for any accounts or certificates related to Keyfactor Command and associated products, especially when these have elevated or administrative access. A strong password has at least 12 characters (more is better) and multiple char-

Tab	Section	Field	Description	
			acter classes (lowercase letters, uppercase letters, numeral, and symbols). Ideally, each password would be randomly generated.  Avoid password re-use.	
Enrollment	PFX	Require Custom Friendly Name	If set to <b>True</b> , requires the user to enter a custom friendly name for the certificate. The default value is False.	
Enrollment	PFX	Enable Legacy Encryption	If set to <b>True</b> , the historical algorithm set (3DES/SHA1/RC2) is used for PFX enrollments. If set to <b>False</b> , the newer algorithm set provided by Windows (AES256/SHA256/AES256) is used instead. The default value is False. <i>This must be set to False for enrollment to work when using Windows Server 2016.</i>	

# **Application Settings: Agents Tab**

Figure 337: Agents Application Settings

Table 21: Agents Application Settings

Tab	Section	Field	Description
Agents	General	Job Failures and Warn- ings Age Out (days)	The number of days orchestrator job failures and warnings should be included in the count of failures on the orchestrator job history tab. The default value is 7.
Agents	General	Certificate Authority For Submitted CSRs	The certificate authority used for reenrollment requests made from the Certificate Stores page. See Certificate  Store Reenrollment on page 426.
Agents	General	Heartbeat Interval (minutes)	The frequency, in minutes, with which an orchestrator (e.g. Keyfactor Universal Orchestrator, Keyfactor Java Agent or Keyfactor Mac Auto-Enrollment Agent) should query the Keyfactor Command orchestrator server for a status on the accuracy of its jobs list. The default value is 5.
Agents	General	Notification Alert Email Recipients	The email address(es) to receive notification.
Agents	General	Notification Alert Interval (minutes)	The timer service has a job that runs based on this application setting. If an orchestrator has not checked in between job runs, an email alert is sent to the configured recipients stating which orchestrator has not been seen.
Agents	General	Send Entropy during on device key generation (ODKG/Reenrollment)	Whether the configure call returns the property <i>Entropy</i> containing 2048 bytes. This property is optional via this app setting. The default is false on upgrades and new installs.
Agents	General	Registration Check Interval (minutes)	The frequency, in minutes, with which an orchestrator should check with the Keyfactor Command server to see if it has been approved as an orchestrator. The default value is 30.
Agents	General	Registration Handler	The maximum number of seconds an

Tab	Section	Field	Description
		Timeout (seconds)	auto-registration handler is allowed to attempt to run before being halted and declared to be deferred. The default value is 90 for more recently installed systems. Keyfactor recommends using a value of at least 60 seconds.
Agents	General	Number of times a job will retry before reporting failure	The number of times an orchestrator job will attempt to retry running if it encounters an error before failing. The default value is 5.
Agents	General	Revoke old Client Auth Certificate	If set to <b>True</b> , revokes the previous certificate used for orchestrator client certificate authentication after the certificate has successfully been renewed using the client certificate authentication renewal extension. The default value is True.
Agents	General	Session Length (minutes)	The frequency, in minutes, with which an orchestrator renews its session with the Keyfactor Command server and obtains a new session token in the absence of any other reason for the orchestrator to renew the session token. The session token is also renewed when an orchestrator job changes (e.g. an inventory schedule changes, a certificate is scheduled for addition to a certificate store, or a certificate is scheduled for removal from a store) or the orchestrator is restarted. The default value is 1380.
Agents	General	Template For Submitted CSRs	The template used for reenrollment requests made from the Certificate Stores page. See Certificate Store Reenrollment on page 426. The template selected for this value must be available for enrollment against the CA listed in the Certificate Authority For Submitted CSRs setting.

Tab	Section	Field	Description
Agents	Authentication	Always Use Certificate from Header	If set to <b>True</b> , the orchestrator will be authenticated using the client certificate provided in the header from the orchestrator rather than client certificate used to make the connection to Keyfactor Command. This is useful in configurations where one certificate is used to authenticate the orchestrator to a proxy and a second certificate is used to authenticate the proxy to Keyfactor Command. The original certificate from the orchestrator can be preserved in the header to present to Keyfactor Command for authentication. The default value is False.
Agents	F5	Ignore Server SSL Warnings	If set to <b>True</b> , the orchestrator will connect to the F5 device using SSL even if it detects a problem with the certificate on the F5 device (e.g. it doesn't trust the issuer of the certificate because the certificate is self-signed). This option applies only to the F5 methods based on the F5 SOAP API (see Certificate Stores on page 409). The F5 methods based on the F5 iControl REST API automatically ignore SSL warnings without the need to set this option. The default value is False.
Agents	SSL	SSL Maximum Discovery Job Size	The maximum number of endpoints for scanning that will be assigned to any one orchestrator for a given discovery scan job part. Together with the SSL Scan Job Timeout setting, this can be used to fine tune the running of SSL discovery scan jobs. The default value is 16,384.  Note: A change made to this setting takes effect with the next discovery scan job. It does not affect currently running jobs.

Tab	Section	Field	Description
Agents	SSL	SSL Maximum Email Results	The maximum number of results to display in an SSL monitoring results email message table of certificates that have expired or are expiring shortly. The default value is 500.
Agents	SSL	SSL Maximum Monitoring Job Size	The maximum number of endpoints for scanning that will be assigned to any one orchestrator for a given monitoring scan job part. Together with the SSL Scan Job Timeout setting, this can be used to fine tune the running of SSL monitoring scan jobs. The default value is 16,384.  Note: A change made to this setting takes effect with the next monitoring scan job. It does not affect currently running jobs.
Agents	SSL	Retain SSL Endpoint History (days)	The number of days old an endpoint history record must be before it is available for deletion by the endpoint history cleanup process. Endpoint history records older than this will be retained if they are the last records for the given endpoint. Both the last discovery and last monitoring records will be retained regardless of age. The default value is 30.
Agents	SSL	SSL Scan Job Timeout (minutes)	The maximum number of minutes any one orchestrator is allowed to attempt to run an SSL scan job before the job for that orchestrator is abandoned and given to the next orchestrator in the orchestrator pool to run (if applicable). The default value is 180.  Note: A change made to this setting takes effect immediately. It applies to currently running jobs as well as future jobs.

Tab	Section	Field	Description
Agents	SSL	SSL Scan User Agent	Defines what is sent to endpoints when Request Robots.txt is enabled on a SSL Network.

# **Application Settings: API Tab**

# Application Settings 9

 $\label{lem:policy} \mbox{Application Settings define operational parameters for the system.}$ 

Figure 338: API Application Settings

Table 22: API Application Settings

Tab	Section	Field	Description
API	General	Allow Deprecated API Calls	If set to <b>False</b> , API applications will not be able to access earlier versions of API methods or other legacy API methods that have been replaced or updated. Many of the updated methods offer additional security measures, so this setting can reduce the risk of unauthorized API access, but may cause API applications written against these earlier versions to stop functioning correctly. If you do not have any such applications, this should be set to <b>False</b> . The default is True. For more information, see <i>Versioning</i> in the <i>Keyfactor API Reference Guide</i> .

Tab	Section	Field	Description
API	General	API Throttling Interval (seconds)	The maximum rate at which API applications can make requests to the API. A larger value will mitigate risks from certain denial of service and brute-force/dictionary attacks, but will limit the performance of applications needing to make multiple API calls. This can be set to zero to disable throttling.
API	Certificate Enrollment	Authorization Token Timeout	This is considered deprecated and may be removed in a future release.
API	Certificate Enrollment	Reverse Legacy Enrollment Chain Order	This is considered deprecated and may be removed in a future release.

# **Application Settings: SSH Tab**

# Application Settings 9

Figure 339: SSH Settings

Table 23: SSH Application Settings

Tab	Section	Field	Description
SSH	General	Key Lifetime (days)	The number of days for which an SSH key generated through My SSH Key (see Generating a New Key on page 537) or Service Account Keys (see Creating a Service Account Key on page 546) is considered valid. The default is 365 days.

Tab	Section	Field	Description
SSH	General	SSH Key Password	The regular expression against which the password entered when creating, rotating or downloading keys for both user SSH keys (My SSH Key on page 532) and service account SSH keys (Service Account Keys on page 543) will be validated. The default is a minimum of 12 characters configured as:  ^.{12,}\$
SSH	General	SSH Key Password Error Message	The error message displayed to the user in the relevant SSH pages of the Keyfactor Command Management Portal when the password referenced does not match the regular expression defined for the password using the SSH Key Password setting.

# **Application Settings: Workflow Tab**

# Application Settings 9

Figure 340: Workflow Settings

Table 24: Workflow Application Settings

Tab	Section	Field	Description
Workflow	General	Workflow Step Run Timeout (seconds)	The number of seconds a workflow instance step will be allowed to run before timing out and setting the instance to a status of Failed. The default is 60 seconds.
Workflow	General	Instance	The number of days to retain completed workflow

Tab	Section	Field	Description	
	Cleanup Days		instances (successful or failed) before they are purged. The cleanup job runs daily at midnight. The default value is 14.	

▶ **Tip:** Click the help icon (②) next to the page title to open the embedded web copy of the *Keyfactor Command Documentation Suite* to this section.

You can also find the help icon at the top of the page next to the **Log Out** button. From here you can choose to open either the *Keyfactor Command Documentation Suite* at the home page or the *Keyfactor API Endpoint Utility*.

#### 2.1.11.2 Security Roles and Claims

There are several elements that make up Keyfactor Command Security infrastructure. To define your security design you will use these elements in combinations that meet your needs. You can limit user menu access through global permissions, and user certificate access through collection and certificate stores permissions.

- Security Roles—Management Portal and Keyfactor API Access Control
   Define the naming convention and structure of your security design by creating a name and
   description for your roles. These roles will then hold the definition of your security design based
   on the menu access, certificate collection access or certificate store access as applied to them.
   The roles will then be applied to users or groups to complete the security set-up. These roles are
  - Grant access to the Management Portal and Keyfactor API, by selecting area access permissions for a role—for example, at what level of permission the user/group can access certificates functionality on the Keyfactor Command Management Portal. See <a href="Security Role">Security Role</a>
     Permissions on page 633 and Security Role Operations on page 685.
  - Grant certificate collection access by selecting role permissions per collection—at which level of permission the user/group can access collection functionality and/or which collections they can access. See Certificate Collection Permissions on page 628.
  - Grant certificate store container access by selecting role permissions per container—at
    which level of permission the user/groups can access certificate store functionality, and/or
    which stores they can access. See Container Permissions on page 630.
- Security Claims (formerly Identities)—Management Portal and Keyfactor API authentication.
   Assign combinations of Roles to users or groups to apply your security design to your users. See Security Claim Operations on page 694.

used to:

#### **Security Roles** Security Roles and Claims 9 Security Roles are used in conjunction with claims to define user access to entities within Keyfactor. Direct permissions may be defined globally, for Certificate Collections, for PAM Providers, and for Certificate Store Containers. Active Directory users, groups, or select OAuth claims may then be associated with these roles, thus granting permissions to users given those claims by a trusted identity provider. Field Comparison SEARCH ADVANCED Name is equal to Total: 9 REFRESH Name Claims Count Immutable Administrator PKI Administrators false Power Users 2 false Read Only 2 false Renewal Handler API 0 false Reporting API Access true Revokers false Special Viewers false

Figure 341: Security Roles

Windows Enroll Gateway

During the Keyfactor Command installation and configuration process, the security role **Administrator** is created (see *Install the Main Keyfactor Command Components on the Keyfactor Command Server(s): AdministrativeUsersTab* in the *Keyfactor Command Server Installation Guide*). The **Administrator** role grants full permissions to the Management Portal and cannot be edited or deleted. If all users of the Management Portal should have full access to all features within the portal, this one role may be sufficient for your needs. However, if you would like to grant access to other users or limit the functionality available to those users, you need to add one or more new security roles for this purpose.

false

A **Reporting API Access** role is automatically created during installation to support the dashboard and reporting access required by the Logi Analytics Platform. The service account user associated with the IIS application pools on the Keyfactor Command Management Portal server (where Logi is installed) is automatically created as an identity and associated with this role.

#### Security Claims Security Roles and Claims 9 Security Roles Claims Claims define security principals with access to the system. The Claim Types may be either OAuth claim values or Active Directory Security Groups, Users, and Computers. These claims are then assigned to Security Roles to grant permission to system resources. A single web server hosting Command should use either OAuth or Active Directory claim types but not both Comparison Value SEARCH ADVANCED Description ✓ is equal to ADD EDIT DELETE VIEW PERMISSIONS VIEW ROLES Total: 6 REFRESH Claim Value Claim Type Provider Description KEYEXAMPLE\bandrasa Active Directory User Active Directory Service Account Active Directory KEYEXAMPLE\svc\_keyservice Active Directory User Reporting KEYEXAMPLE\Keyfactor Administrators Active Directory Group Active Directory Administrators KEYEXAMPLE\svc\_keypool KEYEXAMPLE\sbrown Client Certificate Authentication CA OAuth Role

Figure 342: Security Claims

Claims are created in Keyfactor Command using users or groups. During the Keyfactor Command installation and configuration process, administrative security claims are created using the user and/or group records for your selected identity provider (either Active Directory or an alternative) on the Administrative Users tab of the configuration wizard (see Install the Main Keyfactor Command Components on the Keyfactor Command Server(s): AdministrativeUsersTab in the Keyfactor Command Server Installation Guide). More than one user or group may be entered during configuration, if desired. Claims entered in the configuration wizard are associated with the Administrators role that grants all permissions to the Management Portal.

If you would like to grant access to other users but limit the functionality available to those users, you need to add one or more new security claims for this purpose and link them to one or more appropriate security roles. See Security Claim Operations on page 694.

**Tip**: Click the help icon (2) next to the page title to open the embedded web copy of the *Keyfactor Command Documentation Suite* to this section.

You can also find the help icon at the top of the page next to the **Log Out** button. From here you can choose to open either the *Keyfactor Command Documentation Suite* at the home page or the *Keyfactor API Endpoint Utility*.

#### **Keyfactor Command Security Design Considerations**

As you create your security design, be sure to cover the following:

 Determine the list of users, groups, and other entities who will have access to Keyfactor Command. Access in Keyfactor Command is based on identity provider users and groups or roles (see <u>Identity Providers on page 756</u>). These will be used to create **Security Claims** in Keyfactor Command to which **Security Roles** will be assigned.

**Note**: If you require only one layer of security (all users will have full access) you may wish to simply use the Administrator Role that was created during installation (see *Install the Main Keyfactor Command Components on the Keyfactor Command Server(s): Administrative Users Tab* in the *Keyfactor Command Server Installation Guide*).

**Note**: When defining the users and groups you will use to form **claims**, consider whether you will have a one-to-one or one-to many relationship between **Claims** and **Roles**.

- Define the naming convention for **Security Roles**. Menu access and certificate security will be assigned to **Roles** which in turn will be applied to **Security Claims**.
- Determine the Keyfactor Command menu access and Keyfactor API access as well as the level
  of functionality you want to apply to each Role using the permissions information found Security
  Role Permissions on page 633.
- If you need a further level of control beyond Security Roles, consider Permission Sets. Permission sets are containers which allow you to organize roles and compartmentalize permissions.
   They can only be configured through the Keyfactor API (see Permission Sets in the Keyfactor API Reference Guide).
- Determine certificate security based on collections and certificate store permissions based on containers, if any. See below for more information.

#### **Certificate Store Container Permissions**

When designing a container permission scheme, you need to think first about whether you want your users to have access to all the certificate stores in your Keyfactor Command database or whether you need to limit your users to having access to only a subset of your stores. If you're comfortable granting access to all the stores, you can use the global Read permission. If you're not comfortable with this, you need to use container-level permissions and grant Read permissions on a container-by-container basis. These can be granted separately on a group-by-group (or user-by-user) basis, so group A can be granted global Read while group B is only granted Read to a certain container.

Next, you need to think about what you want your users to be able to do with the stores they have access to. By granting Read access to the stores, you're allowing your users to browse to the certificate stores page and see all the stores and containers that they've been granted access to, but they can perform no operations related to the stores. These are controlled with additional permissions (see below) that can also be set either globally or on a container-by-container basis. You can combine global and container-level security.

**Example:** You've decided that you need to use container-level security at the *Read* level on three different containers rather than granting global *Read* to your Web Server Managers group. You want these users to be able to push new certificates out to certificate stores in the IIS Personal, PEM and Java containers but not to stores on your F5 and NetScaler devices. You could either grant them the *Schedule* permission on a container-by-container basis or you could grant them the global *Schedule* permission for Certificate Store Management. Since the users have neither the global *Read* permission nor container permission for

the containers for the F5 and NetScaler devices, these two settings would accomplish the same goal.

In addition to the permissions that must be considered when designing a permission scheme for certificate stores, you must also give consideration to permissions for certificates. Users must have permissions to certificates in order to use the certificate store operations. See Certificate Collection Permissions on the next page and Container Permissions on page 630.

Note: Setting permissions on a container-by-container basis automatically grants the lower permissions (e.g. setting Schedule automatically grants Read). The same is not true for permissions set at the global level.

Any containers that do not have container-by-container permissions applied fall back to the global permissions, if any global permissions have been set.

## **Certificate and Collection-by-Collection Permissions**

When designing a certificate permission scheme, you need to think first about whether you want your users to have access to all the certificates in your Keyfactor Command database or whether you need to limit your users to having access to only a subset of your certificates. If you're comfortable granting access to all the certificates, you can use the global Read permission. If you're not comfortable with this, you need to use collection-level permissions and grant Read permissions on a collection-by-collection basis. These can be granted separately on a group-by-group (or user-byuser) basis, so group A can be granted global Read while group B is only granted Read to a certain collection.

Next, you need to think about what you want your users to be able to do with the certificates they can view. There are certificate operation permissions (see Certificate Collection Permissions on the next page) that you can set that control what your users can do with the certificates. These can be set either globally or on a collection-by-collection basis. You can combine global and collection-level security.

**Example:** You've decided that you need to use collection-level security at the Read level on four different collections to grant Read access to your PKI Help Desk group and will not grant them global Read permissions. You also want these users to be able to edit the metadata fields of the certificates in all four of these collections. You could either grant them the Edit Metadata permission on a collection-by-collection basis or you could grant them the global Edit Metadata permission. Since the users don't have the global Read permission (and thus can't read the other collections), these two settings would accomplish the same goal.

At the global level, the Certificates Read role permission grants access to both the certificate search page and all certificate collections. Users who have been granted only collection-level Read permissions and not global Read permissions have access only to the collections to which they have been granted access and not to the certificate search page. See Security Role Permissions on page 633 and Certificate Collection Permissions on the next page.

In addition to the **Certificates** role permissions that must be considered when designing a permission scheme for certificates, you must also give consideration to the **Certificate Collections** and **Certificate Store Management** global role permissions.

- Enabling the Certificate Collections Modify global role permission allows users to use the Save, Save As and Delete buttons for a collection. This allows users to create new certificate collections based on existing collections (Save As), delete existing collections (Delete), or modify select settings about an existing collection (Save). Typically, Certificate Collections permissions would only be granted to users who also had at least global Read permissions to allow them to do certificate searches from which to create new collections.
- You will need to consider the Certificate Store Management role permissions if you use certificate stores and want any of your limited access users to make use of the Add to Certificate Store, Remove from Certificate Store, or Renew/Reissue operations on certificates. These certificate operations are only available to users who have also been granted the Read and Schedule role permissions for Certificate Store Management. Permissions to certificate stores can be granted either globally or via container security (see <a href="Certificate Collection Permissions below">Certificate Collection Permissions below</a> and Container Permissions on page 630).

#### **Certificate Collection Permissions**

Permissions on certificates and their collections can be controlled at two levels—system-wide at the certificates-collections level and on a collection-by-collection basis. When designing a certificate permission scheme, you may use entirely system-wide permissions or you may use a combination of system-wide permissions and collection permissions. Both system-wide and collection permissions are configured through Security Roles (see Security Role Operations on page 685).

System-wide certificate permissions are controlled using the **Certificates / Collections** role permission.

# Security Roles and Claims 9

Role Information For: Power Users

Figure 343: Certificate Collection System-wide Permissions

**Note**: The *Import* permission that was previously among the permissions controlled at the system-wide certificate collection level, has moved to a higher level in the permission tree and is no longer found at the collection level.

Permissions for managing collections (modification of existing collections or creation of new collections) are controlled with the system-wide **Certificates** / **Collections** role *Modify* permission. The Certificates Collections Modify permission allows a user to edit the configuration settings that make up the collections (e.g. the query that defines the collection). The permissions set on the Collection Permissions tab allow a user to act on the certificates in the collection.

Figure 344: Certificate Collection per Collection Permissions

Certificate-related permissions can be granted globally or on a collection basis. Both options share the same permission options (see <u>Certificates on page 647</u>) except system-wide certificate permissions have the additional role permissions of *Modify* and *Private Key Import*, which cannot be assigned at the collection level.

Any certificate collections that do not have collection-level permissions applied fall back to the system-wide permissions, if any system-wide permissions have been set for that role.

For more information about configuring collection-level permissions, see <u>Collection Permissions Tab</u> on page 687.

#### **Container Permissions**

Permissions on certificate stores are controlled at two levels—system-wide and on a certificate store container-by-container basis. When designing a certificate store permission scheme, you may use entirely system-wide permissions or you may use a combination of system-wide permissions and container permissions. Both system-wide and container permissions are configured through Security Roles (see Security Role Operations on page 685).

System-wide certificate store permissions are controlled with the **Certificate Store Management** role permissions on the **Global Permissions** tab of the Security Role Information dialog.

# Security Roles and Claims 9

Role Information For: Special Viewers

Figure 345: Certificate Store Management—Global Permissions

Container-by-container permissions are set on the **Container Permissions** tab of the Role Information dialog for each container by name using the same set of permissions.

Any containers that do not have container-by-container permissions applied fall back to the system-wide permissions, if any system-wide permissions have been set for that role.

Figure 346: Certificate Store Management - Container Permissions

Certificate store permissions can be granted system-wide or on a container basis. Both options share the same permission options (see <u>Certificate Stores on page 638</u>). Container permissions work in conjunction with many other security permissions to control access to certificate store related functionality.

For more information about configuring container-level permissions, see <u>Container Permissions Tab</u> on page 688.

Tip: See the detailed tip sections of Certificate Operations on page 46, Certificate Store Operations on page 414 and Certificate Store Types on page 702 for more information regarding which combination of security permissions are required for various operations.

#### **PAM Permissions**

Permissions on PAM can be controlled at two levels—system-wide and on a provider-by-provider basis. When designing a PAM permission scheme, you may use entirely system-wide permissions or you may use a combination of system-wide permissions and provider-level permissions. Both systemwide and provider-level permissions are configured through Security Roles (see Security Role Operations on page 685).

Tip: Users also need Read permissions for System Settings to be able to access the System Settings Icon > Privileged Access Management page, and Modify permissions to modify the settings.

System-wide PAM permissions are controlled using the Privileged Access Management role permission. These permissions control which users have access to viewing and managing any PAM providers you will use in your Keyfactor Command implementation.

# Security Roles and Claims 9

Role Information For: Special Viewers

Figure 347: Global PAM Permissions

PAM provider-level permissions are controlled with the optional provider-by-provider permissions on the PAM Provider Permissions tab of the Security Role Information dialog. The permissions set on the PAM Provider Permissions tab allow a user to access only the referenced PAM provider when selected.

Any PAM providers that do not have provider-level permissions applied fall back to the system-wide permissions, if any system-wide permissions have been set for that security role.

# Role Information For: Special Vie BACK SAVE Avg the tag of the HAM Provider Permissions Claims CyberArk F5 SSL REST Role Information For: Special Vie Avg the tag of the HAM Provider Permissions Claims Claims Claims Claims Claims Read CyberArk F5 SSL REST

Figure 348: PAM Provider Permissions

PAM permissions can be granted system-wide or on a provider basis. Both options share the same permission options (see Privileged Access Management (PAM) on page 664).

## **Security Role Permissions**

The Security Role Permissions that are available to be assigned to security roles within Keyfactor Command are documented below. For release 11.0 of Keyfactor Command, a new permission structure has been introduced. Users of Keyfactor Command through the Management Portal will not see much difference between the older model and the newer model, as the changes are largely behind the scenes. Users of Keyfactor Command through the Keyfactor API will need to understand the new model. Some Keyfactor API endpoints (e.g. v1 Security Roles endpoints) still use the older permission model. Other Keyfactor API endpoints (e.g. v2 Security Roles endpoints) use the newer permission model.

#### **Version Two Permission Model**

The version two permission model was introduced in Keyfactor Command 11.0 and is used when setting security permissions in the Management Portal, with v2 Security Roles Keyfactor API endpoints, and with Keyfactor API Permission Set endpoints.

In the new model, permissions are built from access control strings, which are structured to support permission inheritance. Generally speaking, the more you add to an access control string, the less privilege you are granting to a user in that area of the product. For example, the following access control string grants full control to the entire product:

Add a certificates level to this, and now you've limited this to full control of just functions related to certificates in the product (which would include enrollment, for example):

/certificates/

Add a collections level to this, and now you've limited this further to full control of just options that can be found on the Certificates menu item in the Management Portal, including certificates both in collections and found by direct search, certificate import, and certificate collection management:

/certificates/collections/

Add a read to this, and now you've limited this to just read for items on the Certificates menu:

/certificates/collections/read/

Add a certificate collection ID to this, and now you've locked this down to just read on just the certificates in the certificate collection with ID 5:

/certificates/collections/read/5/

When you apply permissions through the Management Portal, these access control strings are applied for you based on the selections you make in the Role Information dialog when assigning permissions to a role (see <u>Security Role Operations on page 685</u>). When you apply permissions through the Keyfactor API using a newer endpoint (e.g. v2 Security Roles endpoints), you need to specify these access control strings.

Access control strings that are shown below with a # refer to a specific granular ID to which permissions should be granted. When used, they must be specified with an integer in place of the #. For example, use:

/certificate\_stores/read/4/

To refer to the certificate store container with ID 4, not:

/certificate\_stores/read/#/

**Note:** Access control strings always begin and end with a /. If you specify an access control string in the Keyfactor API without the leading or trailing slash, it will not be recognized.

## **Agents**

Table 25: Agents Security Role Permissions v2

Permission Tab	Portal Permis- sion	API Permission	Description

Global	Certificate Authorities > Read	/certificate_author- ities/read/	Users can view certificate authority records. Users can view revocation monitoring settings, CA health monitoring and threshold alert recipients and schedules.

### **Certificate Stores**

Table 29: Certificate Stores Security Role Permissions v2

See <u>Container Permissions on page 630</u>, <u>Certificate Operations on page 46</u>, <u>Certificate Store Types on page 702</u> and <u>Certificate Store Operations on page 414</u> for more information.

Permission Tab	Portal Permis- sion	API Permission	Description
Global	Certificate Stores	/certificate_stores/	Users can view and manage all certificate stores and add certificates to certificate stores, renew/reissue certificates, and remove certificates from certificate stores for all certificate stores.

Permission Tab	Portal Permis- sion	API Permission	Description
		/certificate_stores/-modify/	Users with the Modify role permission for either Certificate Stores or a container (#) can view the certificate stores grid and the containers grid and use the following operations on these pages. The Modify permission must be granted in conjunction with either Certificate Stores Read or container (3) Read for full functionality.  Users must have global Certificate Stores Read and Modify permissions to access the discover tab and use the functions on it.  Users with Modify permissions granted at the container level can perform these certificate store operations (in addition to those available with Read permissions):  • Add—When a new certificate store is added, only containers on which the user has Modify permissions will appear in the container dropdown and the newly created certificate store must be added to one of these if the user does not have global certificate store management permissions.  • Edit—Only certificate stores in containers on which the user has Modify permissions will be editable.  • Delete—Only certificate stores in containers on which the user has Modify permissions will be available for deletion.  • Assign Container—The container
			assigned to a certificate store can only be changed if the store is currently in a container on which the user has <i>Modify</i> permissions, and the store can only be assigned

Permission Tab	Portal Permis- sion	API Permission	Description
			to another container on which the user has Modify permissions. The user must have Modify permissions on both the source container and the target container when moving a certificate store from one container to another.  • Set New Password—Only certificate stores in containers on which the user has Modify permissions will be available for password reset.  • Reenrollment—Only certificate stores in containers on which the user has Schedule permissions, along with Enroll CSR permissions (see Certificate Enrollment on page 674) will be available for reenrollment.  Note that this permission does not control additions of certificates to certificate stores.
Container	Certificate Stores > Modify	/certificate_stores/- modify/#/	Users with the <i>Modify</i> role permission for either <b>Certificate Stores</b> or a container (#) can view the certificate stores grid and the containers grid and use the following operations on these pages. The <i>Modify</i> permission must be granted in conjunction with either <b>Certificate Stores</b> <i>Read</i> or container (3) <i>Read</i> for full functionality.  Users must have global <b>Certificate Stores</b> <i>Read</i> and <i>Modify</i> permissions to access the discover tab and use the functions on it.  Users with <i>Modify</i> permissions granted at the container level can perform these <i>certificate</i> store operations (in addition to those available with <i>Read</i> permissions):

Permission Tab	Portal Permis- sion	API Permission	Description
			<ul> <li>Add—When a new certificate store is added, only containers on which the user has Modify permissions will appear in the container dropdown and the newly created certificate store must be added to one of these if the user does not have global certificate store management permissions.</li> <li>Edit—Only certificate stores in containers on which the user has Modify permissions will be editable.</li> <li>Delete—Only certificate stores in containers on which the user has Modify permissions will be available for deletion.</li> <li>Assign Container—The container assigned to a certificate store can only be changed if the store is currently in a container on which the user has Modify permissions, and the store can only be assigned to another container on which the user has Modify permissions. The user must have Modify permissions on both the source container and the target container when moving a certificate store from one container to another.</li> </ul>
			<ul> <li>Set New Password—Only certificate stores in containers on which the user has Modify permissions will be available for password reset.</li> <li>Reenrollment—Only certificate stores in containers on which the user has Schedule permissions, along with Enroll CSR permissions</li> </ul>
			(see Certificate Enrollment on page 674) will be available for reenrollment.

Note that this permission does not control additions of certificates to certificate stores.
Users with the Read global role permission for either Certificate Store or a specific container (#) can view the certificate stores grid and the containers grid and see all the certificate stores and store types. They can perform no operations on the certificate stores or containers from the certificate stores page.  If the users also have global Read permissions for Certificates > Collections, they can view inventory for a certificate store by highlighting a certificate store in the certificate store grid and clicking the View Inventory button.  Users with Read permissions granted at the container level can perform these certificate store operations:  • View—Only certificate stores in containers on which the user has Read permissions will appear in the certificate stores grid. Users can open each certificate store to view the details of it but cannot change them.  • View Inventory—Only certificate stores in containers on which the user has Read permissions will be available with the View Inventory option.  Users with Read permissions granted at the container level can perform these container operations:  • View—Only containers on which the user has Read permissions granted at the container level can perform

Permission Tab	Portal Permis- sion	API Permission	Description
			appear in the containers grid. Users can open each container to view the details of it but cannot change them.
Container	Certificate Stores > Read	/certificate_ stores/read/#/	Users with the <i>Read</i> global role permission for either <b>Certificate Stores</b> or a specific container (#) can view the certificate stores grid and the containers grid and see all the certificate stores and store types. They can perform no operations on the certificate stores or containers from the certificate stores page.  If the users also have global <i>Read</i> permissions for <b>Certificates &gt; Collections</b> , they can view inventory for a certificate store by highlighting a certificate store in the certificate store grid and clicking the <b>View Inventory</b> button.  Users with <i>Read</i> permissions granted at the container level can perform these <i>certificate store</i> operations:  • <b>View</b> —Only certificate stores in containers on which the user has <i>Read</i> permissions will appear in the certificate stores grid. Users can open each certificate store to view the details of it but cannot change them.  • <b>View Inventory</b> —Only certificate stores in containers on which the user has <i>Read</i> permissions will be available with the View Inventory option.  Users with <i>Read</i> permissions granted at the container level can perform these <i>container</i> operations:  • <b>View</b> —Only containers on which the

Permission Tab	Portal Permis- sion	API Permission	Description
			user has <i>Read</i> permissions will appear in the containers grid. Users can open each container to view the details of it but cannot change them.
Global	Certificate Stores > Schedule	/certificate_ stores/schedule/	Users with the Schedule and Read role permission for either Certificate Stores or a container (#) can use the Add to Certificate Store, Remove from Certificate Store from the certificate search page, and Schedule from the certificate stores page.  Users must have either global Read for Certificates > Collections or have been granted access to one or more certificate collections via collection-level permissions (see Certificate Collection Permissions on page 628) to use the add, remove, and renew/reissue certificate options. To renew/reissue certificates, users must also have been assigned to a role with Certificates > Enrollment permissions (PFX and/or CSR (see Certificate Enrollment on page 674)) and Agents > Management-Read Users with Schedule and Read permission may perform this operation on the certificate store or container grid.  • Schedule Inventory—Only certificate stores in containers on which the user has Schedulepermissions will be available for scheduling inventory.  Users with Schedule and Read permissions granted at the container level can perform these certificate operations:  • Add to Certificate Store—Only

Permission Tab	Portal Permis- sion	API Permission	Description
			certificate stores in containers on which the user has Schedule permissions will be available for adding a certificate to in certificate collections or certificate search.  • Remove from Certificate Store— Only certificate stores in containers on which the user has Schedule permissions will be available for removing a certificate from in certificate collections or certificate search.  • Renew/Reissue—Only certificate stores in containers on which the user has Schedule permissions will be available for renewing or reissuing a certificate in certificate collections or certificate search.
Container	Certificate Stores > Schedule	/certificate_ stores/schedule/#/	Users with the Schedule and Read role permission for either Certificate  Stores or a container (#) can use the Add to Certificate Store, Remove from Certificate Store from the certificate search page, and Schedule from the certificate stores page.  Users must have either global Read for Certificates > Collections or have been granted access to one or more certificate collections via collection-level permissions (see Certificate Collection Permissions on page 628) to use the add, remove, and renew/reissue certificate options. To renew/reissue certificates, users must also have been assigned to a role with Certificates > Enrollment permissions (PFX and/or CSR (see Certificate Enrollment on page 674)) and Agents >

Permission Tab	Portal Permis- sion	API Permission	Description
			Management-Read Users with Schedule and Read permission may perform this operation on the certificate store or container grid.  Schedule Inventory—Only certificate stores in containers on which the user has Schedulepermissions will be available for scheduling inventory.
			Users with Schedule and Read permissions granted at the container level can perform these certificate operations:  • Add to Certificate Store—Only certificate stores in containers on which the user has Schedule permissions will be available for adding a certificate to in certificate collections or certificate search.
			Remove from Certificate Store— Only certificate stores in containers on which the user has Schedule permissions will be available for removing a certificate from in certificate collections or certificate search.
			<ul> <li>Renew/Reissue—Only certificate stores in containers on which the user has Schedule permissions will be available for renewing or reis- suing a certificate in certificate collections or certificate search.</li> </ul>

# **Certificate Templates**

**Note:** This permission was previously bundled together with certificate authority permissions and known as PKI Management.

Table 30: Certificate Templates Security Role Permissions v2

Permission Tab	Portal Permis- sion	API Permission	Description
Global	Certificate Templates	/certificate_ templates/	Users can view and modify certificate template records.
Global	Certificate Templates > Read	/certificate_ templates/read/	Users can view certificate template records.
Global	Certificate Templates > Modify	/certificate_ templates/modify/	Users can modify certificate template settings to import, edit, and configure system settings for certificate templates.

### Certificates

See Certificate Collection Permissions on page 628 for additional information.

Table 31: Certificates Security Role Permissions v2

Permission Tab	Portal Permission	API Permission	Description
Global	Certificates	/certificates/	Users can view, modify, and act upon everything certificate-related, including certificates in collections, certificates found in a search that are not in a collection, certificate import, certificate enrollment, and pending certificate request management.
Global	Certificates > Import	/certificates/import/	Users can import certificates using the Management Portal Add Certificate page or the Keyfactor API POST /Cer- tificates/Import

Permission Tab	Portal Permission	API Permission	Description
			method. Users who also have Read permissions for Certificate Store Management or container permissions can add certificates to certificate stores from Add Certificate.
			Note: This permission was controlled at the global certificate collection level in previous versions of Keyfactor Command, but has moved to a higher level separate from collections.
Global	Certificates > Requests Manage	/certificates/requests/manage/	Users can use the Pending CSRs page in the Management Portal and the equivalent API functions.
Global	Certificates > Enrollment	/certificates/enrollment/	Users can use all the enrollment-related functions, including CSR generation, CSR enrollment, and PFX enrollment.
Global	Certificates >	/certificates/enrollment/pfx/	Users can use the

Permission Tab	Portal Permission	API Permission	Description
	Enrollment > Pfx		PFX Enrollment page in the Management Portal and the equivalent API functions.
Global	Certificates > Enrollment > Csr	/certificates/enrollment/csr/	Users can use the CSR Enrollment page in the Management Portal and the equivalent API functions.
Global	Certificates > Enrollment > Csr > Generation	/certificates/enrollment/csr/generation/	Users can use the CSR Generation page in the Management Portal and the equivalent API functions.
Global	Certificates > Collections	/certificates/collections/	Users can view, modify, and act upon certificate-related functions including certificates in collections and certificates found in a search that are not in a collection.
Global	Certificates > Collections > Delete	/certificates/collections/delete/	Users can delete certificates and, if applicable, the private keys of the certificates from the Keyfactor Command database for any certificates.
Collection	Certificates > Collections > Delete	/certificates/collections/delete/#/	Users can delete certificates and, if applicable, the private keys of the certificates from the

Permission Tab	Portal Permission	API Permission	Description
			Keyfactor Command database for certificates in the specified certificate collection.
Global	Certificates > Collections > Metadata Modify	/certificates/collections/metadata/modify/	Users can modify certificate metadata for certificates in the Certificate Details on page 20 dialog (only information on the metadata tab can be edited) and the equivalent API functions for any certificates.
Collection	Certificates > Collections > Edit Metadata	/cer- tificates/collections/metadata/modify/#/	Users can modify certificate metadata for certificates in the Certificate Details on page 20 dialog (only information on the metadata tab can be edited) and the equivalent API functions for certificates in the specified certificate collection.
Global	Certificates > Collections > Modify	/certificates/collections/modify/	Users can add or edit certificate collections. See Certificate Collection Permissions on page 628 for more information.
			Note: This permission cannot be applied at the

Permission Tab	Portal Permission	API Permission	Description
			certificate collection level.
Global	Certificates > Collections > Private Key Import	/certificates/collections/private_key/import/	Users can save the private key for the certificate in the Keyfactor Command database.  Users with this role can add a certificate with an associated private key through the Add Certificate option under the Certificate Locations menu (see Add Certificate on page 74) and the private key will be stored in the Keyfactor Command database. Users must also be granted the Import role in order to be able to use the Add Certificate feature.  Note: This permission cannot be applied at the certificate collection level.
Global	Certificates > Collections > Download with Private Key	/certificates/collections/private_key/read/	Users can download the certificates with their private key for all certificates.

Permission Tab	Portal Permission	API Permission	Description
Collection	Certificates > Collections > Private Key Read	/certificates/collections/private_ key/read/#/	Users can download the certificates with their private key for certificates in the specified certificate collection.
Global	Certificates > Collections > Read	/certificates/collections/read/	Users can view any certificates, including certificates, including certificate history, and can download certificates. Users who also have Read permissions for Certificate Store Management or certificate store container permissions can add certificates to certificate stores from Certificate Search and Certificate Collections.  The certificate operations possibly available to users with this permission are:  • Add to Certificate Store (Also requires the Certificate Stores > Schedule permission at either the global or container level)  • Display  • Download  • Get CSV  • Identity Audit (Also requires the

Permission Tab	Portal Permission	API Permission	Description
			Security > Read permission)  Include Revoked checkbox  Include Expired checkbox  Renew (Also requires the Certificates > Enroll- ment > Pfx permission and Certificate Stores > Schedule permission at either the global or container level)  Remove from Certificate Store (Also requires the Certificate Stores > Schedule permission at either the global or container level)
			Users with global Read role permissions can browse to Certificate Search in the Management Portal and view all saved certificate collections. They can view any certificate in the Keyfactor Command database and are not limited to just those returned by select collections. Users with this permission can view

Permission Tab	Portal Permission	API Permission	Description
			the certificates returned by searches and open the details of the certificates.
Collection	Certificates > Collections > Read	/certificates/collections/read/#/	Users can view certificates in the specified certificate collection, including certificate history, and can download certificates. Users who also have Read permissions for Certificate Store Management or certificate store container permissions can add the certificates in the collection to certificate stores from Certificate Search and Certificate Collections.  The certificate operations possibly available to users with this permission are:  • Add to Certificate Store (Also requires the Certificate Stores > Schedule permission at either the global or container level)  • Display  • Download  • Get CSV  • Identity Audit

Permission Tab	Portal Permission	API Permission	Description
			(Also requires the Security > Read permission)  Include Revoked checkbox  Include Expired checkbox  Renew (Also requires the Certificates > Enrollment > Pfx permission and Certificate Stores > Schedule permission at either the global or container level)  Remove from Certificate Stores (Also requires the Certificate Store (Also requires the Certificate Stores > Schedule permission at either the global or container level)
			Users with collection-level Read role permissions on a collection will see the collections to which they have been granted access appear on the Certificate Collections menu (if they have been configured to appear on the menu—see Certificate  Collection Manager on page 85). The

Permission Tab	Portal Permission	API Permission	Description
			users will be able to view all the certificates in the collections and open the details of the certificates.
Global	Certificates > Collections > Revoke	/certificates/collections/revoke/	Users can revoke any certificates through Keyfactor Command. This includes certificates that have been issued by a Microsoft or EJBCA CA configured for synchronization or by a cloud-based certificate vendor that is managed via a Keyfactor certificate gateway.  Important: In order to successfully revoke certificates, the service account under which the Keyfactor Command application pool is running must be granted

Permission Tab	Portal Permission	API Permission	Description
		API Permission	"Issue and Manage Certificates" and "Manage CA" permissions to the CA database as per Create Active Directory Groups to Control Access to Keyfactor Command Features in the Keyfactor Command Server Installation Guide, or, if delegation is configured for the CA, the user executing the revoke must have the "Issue and Manage Certificates" permissions while the application pool service
			account has the "Manage CA" permis- sions. If you

Permission Tab	Portal Permission	API Permission	Description
			are using explicit credentials to authenticate your CA (see Adding or Modifying a CA Record on page 355), it is the user specified on the CA configuration in Keyfactor Command who must have permissions on the CA.
Collection	Certificates > Collections > Revoke	/certificates/collections/revoke/#/	Users can revoke certificates in the specified certificate collection through Keyfactor Command. This includes certificates that have been issued by a Microsoft or EJBCA CA configured for synchronization or by a cloud-based certificate vendor that is managed via a Keyfactor certificate gateway.

Permission Tab	Portal Permission	API Permission	Description
			Important: In order to successfully revoke certificates, the service account under which the Keyfactor Command application pool is running must be granted "Issue and Manage Certificates" and "Manage CA" permissions to the CA database as per Create Active Directory Groups to Control Access to Keyfactor Command Features in the Keyfactor Command Server Installation Guide, or, if delegation is configured for the CA, the

Permission Tab	Portal Permission	API Permission	Description
		AFT Perillission	user executing the revoke must have the "Issue and Manage Certi- ficates" permissions while the application pool service account has the "Manage CA" permis- sions. If you are using explicit credentials to authenticate your CA (see Adding or Modifying a CA Record on page 355), it is the user specified on the CA config- uration in Keyfactor Command
			who must have permis- sions on the CA.

## Dashboard

Table 32: Dashboard Security Role Permissions v2

Permission Tab	Portal Permis- sion	API Permission	Description
Global	Dashboard	/dashboard/	Users can view the panels, including the risk header, on their personalized dashboard and add and remove the customizable panels.
Global	Dashboard > Read	/dashboard/read/	Users can view the panels on their personalized dashboard and add and remove them.
Global	Dashboard > Risk Header	/dashboard/risk_ header/	Users can view the risk header at the top of the dashboard.
Global	Dashboard > Risk Header > Read	/dashboard/risk_ header/read/	Users can view the risk header at the top of the dashboard.

# **Identity Providers**

Table 33: Identity Providers Security Role Permissions v2

Permission Tab	Portal Permis- sion	API Permission	Description
Global	Identity Providers	/identity_providers/	Users can view and modify the identity provider settings for identity providers.
Global	Identity Providers > Modify	/identity_provider- s/modify/	Users can modify the identity provider settings for identity providers.
Global	Identity Providers > Read	/identity_provider- s/read/	Users can view the identity provider settings for identity providers.

### Metadata

Table 34: Certificate Metadata Types Security Role Permissions v2

Permission Tab	Portal Permis- sion	API Permission	Description
Global	Metadata	/metadata/	Users can view and modify custom metadata attribute definitions.
Global	Metadata > Types	/metadata/types/	Users can view and modify custom metadata attribute definitions.
Global	Metadata > Types > Read	/metadata/types/read/	Users can view custom metadata attribute definitions on the Certificate Metadata page in the Management Portal and the equivalent API functions.
Global	Metadata > Types > Modify	/metadata/types/modify/	Users can add, edit, and delete custom metadata attribute definitions on the Certificate Metadata page in the Management Portal and the equivalent API functions.

# Monitoring

Table 35: Monitoring Security Role Permissions v2

Permission Tab	Portal Permis- sion	API Permission	Description
Global	Monitoring	/monitoring/	Users can view, modify, and test the pending, issued, and denied certificate request alerts and the event handler registration settings.
Global	Monitoring > Workflow	/monitoring/workflow/	Not in use.
Global	Monitoring >	/monitoring/handlers/	Users can view

Permission Tab	Portal Permis- sion	API Permission	Description
	Handlers		and modify the event handler registration settings.
Global	Monitoring > Handlers > Registration	/monitoring/handlers/registration/	Users can view and modify the event handler registration settings.
Global	Monitoring > Handlers > Registration > Modify	/monitoring/handlers/registration/modify/	Users can modify the event handler regis- tration settings.
Global	Monitoring > Handlers > Registration > Read	/monitoring/handlers/registration/read/	Users can view the event handler registration settings.
Global	Monitoring > Alerts	/monitoring/alerts/	Users can view, modify, and test the pending, issued, and denied certi- ficate request alerts.
Global	Monitoring > Alerts > Modify	/monitoring/alerts/modify/	Users can modify the pending, issued, and denied certi- ficate request alerts, including the alert text, recipients, and event handlers. Users can also add new alerts, delete alerts, and configure

Permission Tab	Portal Permis- sion	API Permission	Description
			the pending alert delivery schedule.
Global	Monitoring > Alerts > Read	/monitoring/alerts/read/	Users can view the pending, issued, and denied certificate request alerts.
Global	Monitoring > Alerts > Test	/monitoring/alerts/test/	Users can test the pending certificate request alerts, including sending email to recipients. Users must also have Read permis- sions for Alerts.

# Privileged Access Management (PAM)

Table 36: Privileged Access Management Security Role Permissions v2

Permission Tab	Portal Permis- sion	API Permission	Description
Global	Pam	/pam/	Users can view and modify any PAM provider.
Global	Pam > Modify	/pam/modify/	Users can add, edit, and delete any PAM provider.
PAM Provider	Pam > Modify	/pam/modify/#/	Users can add, edit, and delete the specified PAM provider.
Global	Pam > Read	/pam/read/	Users can view any PAM provider. Users can select any PAM providers to provide credentials within Keyfactor Command for:  Certificate Stores Certificate Authorities

Permission Tab	Portal Permis- sion	API Permission	Description
			Workflow Definitions
PAM Provider	Pam > Read	/pam/read/#/	Users can view or select the specified PAM provider.

# [Management] Portal

Table 37: Management Portal Security Role Permissions v2

Permission Tab	Portal Permis- sion	API Permis- sion	Description
Global	Portal	/portal/	Users can access the Management Portal.
Global	Portal > Read	/portal/read/	Users can access the Management Portal. This permission must be enabled for all roles that will access the Management Portal.

# Reports

Table 38: Reports Security Role Permissions v2

Permission Tab	Portal Permis- sion	API Permission	Description
Global	Reports	/reports/	Users can generate, view, and modify the delivery schedule for reports. Users can add, edit, and delete custom reports.
Global	Reports > Modify	/reports/modify/	Users can modify the delivery schedule for reports in Report Manager in the Management Portal and the equivalent API functions and add, edit, and delete custom reports.
			Note: Report scheduling is limited by collection permissions. Users in roles that have Reports > Read and Modify permissions will also need to have either global certificate Read permissions or Read collection permissions on indi-

Permission Tab	Portal Permis- sion	API Permission	Description
			vidual collections to have the ability to add, edit, and delete schedules associated with collections. The user will not have access to add, edit, and delete schedules for any collections for which they do not have collection Read permissions in addition to Reports permissions if permissions are granted at a collection-by-collection level rather than globally.
Global	Reports > Read	/reports/read/	Users can generate and view reports.

### **Scripts**

Table 39: Scripts Security Role Permissions v2

Permission Tab	Portal Permis- sion	API Permission	Description
Global	Scripts	/scripts/	Users can view and modify scripts used in alert event handlers and workflows.
Global	Scripts > Modify	/scripts/modify/	Users can add, edit, and delete scripts used in alert event handlers and workflows.
Global	Scripts > Read	/scripts/read/	Users can view scripts used in alert event handlers and workflows.

#### Security

**Note**: Users can only edit security settings on security roles that are in a permission set to which they have been mapped. In some environments, there is only one permission set to which all users are mapped. Other environments may have implemented a more privileged access model with multiple permission sets. For more information on permission sets, see Permission Sets in the *Keyfactor API Reference Guide*.

Table 40: Security Settings Security Role Permissions v2

Permission Tab	Portal Permis- sion	API Permission	Description
Global	Security	/security/	Users can view and modify the settings for Security Roles and Security Claims.
Global	Security > Modify	/security/modify/	Users can modify the settings for Security Roles and Security Claims.
Global	Security > Read	/security/read/	Users can view the settings for Security Roles and Security Claims. Users must also have the Read permission for System Settings to access this in the Management Portal.

#### SSH

See <u>SSH Permissions on page 598</u> for additional information.

Table 41: SSH Security Role Permissions v2

Permission Tab	Portal Permis- sion	API Permission	Description
Global	Ssh	/ssh/	Users can use all SSH functions.
Global	Ssh > Enterprise Admin	/ssh/enterprise_ admin/	Users can use all SSH functions.
Global	Ssh > Server Admin	/ssh/server_admin/	Users can use all SSH functions, except creating server groups and assigning server group owners. Users have limited access to some functions based on server group ownership.
Global	Ssh > User	/ssh/user/	Users can generate their own SSH keys.

### SSL

Table 42: SSL Management Security Role Permissions v2

Permission	Portal Permis-	API Permis-	Description
Tab	sion	sion	
Global	Ssl	/ssl/	Users can view and modify the SSL Discovery settings.

Permission Tab	Portal Permis- sion	API Permis- sion	Description
Global	Ssl > Modify	/ssl/modify/	<ul> <li>Users can modify the SSL Discovery settings:</li> <li>Create, edit, and delete networks, including scan schedules and notification recipients</li> <li>Add, edit, and delete network ranges for networks</li> <li>Add, edit, and delete agent pools</li> <li>Add and remove discovered endpoints from monitoring</li> </ul>
Global	Ssl > Read	/ssl/read/	Users can view the SSL Discovery pages in the Management Portal and the equivalent API functions, including defined networks and the network ranges configured for them, agent pools, and scan results. Users can use the query tool on the Results tab to find discovered endpoints and then view the discovered endpoints, including the details for the endpoints.

### **System Settings**

**Note**: Users can only edit security settings on security roles that are in a permission set to which they have been mapped. In some environments, there is only one permission set to which all users are mapped. Other environments may have implemented a more privileged access model with multiple permission sets. For more information on permission sets, see Permission Sets in the *Keyfactor API Reference Guide*.

Table 43: System Settings Permissions v2

Permission Tab	Portal Permis- sion	API Permission	Description
Global	System Settings	/system_settings/	<ul> <li>Users can modify the System Settings for:</li> <li>Update SMTP Configuration for email delivery of reports and alerts</li> <li>Installed components, including removing servers from use</li> <li>Licensing, including the option to replace the existing license file</li> </ul>

Permission Tab	Portal Permis- sion	API Permission	Description
Global	System Settings > Modify	/system_setting- s/modify/	Users can modify the System Settings for:  • Update SMTP Configuration for email delivery of reports and alerts  • Installed components, including removing servers from use  • Licensing, including the option to replace the existing license file
Global	System Settings > Read	/system_setting- s/read/	Users can view the System Settings for:  • SMTP Configuration for email delivery of reports and alerts  • Installed components  • Licensing  • General Alerts and Warnings about the health of the Keyfactor Command system (not related to a specific area of the product)

## Workflows

Table 44: Workflows Security Role Permissions v2

Permission Tab	Portal Permis- sion	API Permission	Description
Global	Workflows	/workflows/	Users can view and modify the configured workflow definitions and view and manage all initiated workflow instances.
Global	Workflows > Definitions	/workflows/definitions/	Users can view and modify the configured workflow definitions.
Global	Workflows > Definitions > Modify	/workflows/definitions/modify/	Users can modify both the built-in and any custom workflow defin- itions, including the name and description

Permission Tab	Portal Permis- sion	API Permission	Description
			and the configuration for the steps. Users can also add new workflow definitions, delete workflow definitions, publish workflow definitions, and import and export workflow definitions.
Global	Workflows > Definitions > Read	/workflows/definitions/read/	Users can view the configured workflow definitions.
Global	Workflows > Instances	/workflows/instances/	Users can view and manage all initiated workflow instances.
Global	Workflows > Instances > Manage	/workflows/instances/manage/	Users can manage initiated workflow instances, including stopping, restarting, and deleting them.
Global	Workflows > Instances > Read	/workflows/instances/read/	Users can view all the workflow instances that have been initiated.
Global	Workflows > Instances > Read > Mine	/workflows/instances/read/mine/	Users can view the workflow instances that have been initiated by them (e.g. because they enrolled for a certificate).
Global	Workflows > Instances > Read > Pending	/workflows/instances/read/pending/	Users can view the workflow instances that have been initiated and are awaiting input from them.

Permission Tab	Portal Permis- sion	API Permission	Desc	ription
				Tip: There is not a security permission at this level that controls whether users can provide input (a signal) to a workflow instance. This is controlled using the security roles configured on the specific workflow definition. Any user who holds one of the roles configured in the workflow step that requires a signal may provide the necessary input. The user does not need to hold the Workflows > Instances > Read > Pending permission in order to provide the
				input.

### **Version One Permission Model**

The version one permission model was largely replaced in Keyfactor Command version 11.0, but is retained for backwards compatibility for use with select Keyfactor API endpoints.

# **Agent Auto-Registration**

Table 45: Agent Auto-Registration Security Role Permissions v1

Portal Permis- sion	API Permission	Description
Read	AgentAutoRegistration: Read	Users can view the orchestrator auto-registration settings; users must also have <i>Read</i> permissions for Agent Management to access this page in the Management Portal.
Modify	AgentAutoRegistration:  Modify	Users can modify the orchestrator auto-registration settings.

# **Agent Management**

Table 46: Agent Management Security Role Permissions v1

Portal Permis- sion	API Permission	Description
Read	AgentManagement: Read	<ul> <li>View orchestrators, including filtering the Orchestrator Management grid</li> <li>View orchestrator jobs, including status, schedules, failures and warnings</li> </ul>
Modify	AgentManagement:  Modify	<ul> <li>Users can:</li> <li>Manage orchestrators, including approving and disapproving them</li> <li>Unschedule and reschedule orchestrator jobs</li> </ul>

## **Alerts**

Table 47: Alerts Security Role Permissions v1

Portal Permis- sion	API Permission	Description
Read	WorkflowManagement: Read	Users can view the pending, issued, and denied certificate request alerts.
Modify	WorkflowManagement:  Modify	Users can modify the pending, issued, and denied certificate request alerts, including the alert text, recipients, and event handlers. Users can also add new alerts,

Portal Permis- sion	API Permission	Description
		delete alerts, and configure the pending alert delivery schedule.
Test	WorkflowManagement: Test	Users can test the pending certificate request alerts, including sending email to recipients. Users must also have Read permissions for Alerts.

# **Application Settings**

Table 48: Application Settings Security Role Permissions v1

Portal Permission	API Permission	Description
Read	ApplicationSettings: Read	Users can view the application settings.
Modify	ApplicationSettings: Modify	Users can modify the application settings.

# **Auditing**

Table 49: Auditing Security Role Permissions v1

Portal Permis- sion	API Permis- sion	Description
Read	Auditing: Read	Users can access the Audit Log page in the Management Portal, and will be able to make API requests to obtain data from the audit log (query, etc.). The System Settings dropdown menu will display the Audit Log option to users with the <b>Auditing</b> Read permission.

## **Certificate Collections**

Table 50: Certificate Collections Security Role Permissions v1

Portal Permis- sion	API Permission	Description
Modify	CertificateCollections:  Modify	Users can add or edit Certificate Collections. See Certificate Collection Permissions on page 628 for more information.

## **Certificate Enrollment**

Table 51: Certificate Enrollment Security Role Permissions v1

Portal Permission	API Permission	Description
Enroll PFX	CertificateEnrollment: EnrollPFX	Users can use the PFX Enrollment page in the Management Portal and the equivalent API functions.
Enroll CSR	CertificateEnrollment: EnrollCSR	Users can use the CSR Enrollment page in the Management Portal and the equivalent API functions.
CSR Generation	CertificateEnrollment: CsrGeneration	Users can use the CSR Generation page in the Management Portal and the equivalent API functions.
Manage Pending CSRs	CertificateEnrollment: PendingCsr	Users can use the Pending CSRs page in the Management Portal and the equivalent API functions.

## **Certificate Metadata Types**

Table 52: Certificate Metadata Types Security Role Permissions v1

Portal Permis- sion	API Permission	Description
Read	CertificateMetadataTypes: Read	Users can read custom metadata attribute definitions on the Certificate Metadata page in the Management Portal and the equivalent API functions.
Modify	CertificateMetadataTypes:  Modify	Users can add, edit, and delete custom metadata attribute definitions on the Certificate Metadata page in the Management Portal and the equivalent API functions.

# **Certificate Requests**

Table 53: Certificate Requests Security Role Permissions v1

Portal Permis- sion	API Permission	Description
Manage	WorkflowManagement: Participate	Users can participate in the pending, issued, and denied alerts by approving or denying certificate requests from the Certificate Requests page, from the individual pages reached from links included in alerts, or using the

Portal Permis- sion	API Permission	Description
		Keyfactor API /Workflow/Certificates endpoints.
		Note: In previous versions of Keyfactor Command, this permission was Workflow Management: Participate.

## **Certificate Store Management**

Table 54: Certificate Store Management Security Role Permissions v1

See Container Permissions on page 630, Certificate Operations on page 46, Certificate Store Types on page 702 and Certificate Store Operations on page 414 for more information.

UI Permission	API Permission	Description
Read	CertificateStoreManagement: Read	Users can view the certificate stores and containers tabs on the <i>Locations &gt; Certificate Stores</i> menu, and view certificate store types.
Schedule	CertificateStoreManagement: Schedule	Users can add certificates to certificate stores, renew/reissue certificates, schedule and remove certificates from certificate stores.
Modify	CertificateStoreManagement:  Modify	Users can manage all operations regarding certificate stores—including the stores, containers, and discovery process—and certificate store types.

## Certificates

Table 55: Certificates Security Role Permissions v1

Portal Permis- sion	API Permission	Description
Read	Certificates: Read	Users can view certificates, including certificate history, and can download certificates. Users who also have Read permissions for Certificate Store Management or certificate store container permissions can add certificates to certificate stores from Certificate Search and Certificate Collections. The certificate operations possibly available to users with this permission are:

Portal Permission	API Permission	Description
		<ul> <li>Add to Certificate Store (Also requires the Read and Schedule Certificate Store Management permissions)</li> <li>Edit</li> <li>Download</li> <li>Get CSV</li> <li>Identity Audit (Also requires the Read Security Settings permission)</li> <li>Include Revoked checkbox</li> <li>Include Expired checkbox</li> <li>Renew (Also requires the Read and Schedule Certificate Store Management permissions)</li> <li>Remove from Certificate Store (Also requires the Read and Schedule Certificate Store Management permissions)</li> <li>This permission can be applied at either the global or certificate collect level (see Certificate Collection Permissions on page 628.</li> <li>Users with global Read role permissions can browse to Certificate Search in the Management Portal and view all saved certificate collections. They can view any certificate in the Keyfactor Command database and are not limited to just those returned by select collections. Users with this permission can view the certificates returned by searches and open the details of the certificates.</li> <li>Users with collection-level Read role permissions on a collection will see the collections to which they have been granted access appear on the Certificate Collections menu (if they have been configured to appear on the menu—see Certificate Collection Manager on page 85). The users will be able to view all the certificates in the collections and open the details of the certificates in the collections and open the details of the certificates.</li> </ul>
Edit Metadata	Certificates: EditMetadata	Users can modify certificate metadata for certificates in the Certificate Details on page 20 dialog (only information on the metadata tab can be edited) and the equivalent API functions. If the users have also been granted global <i>Read</i> permission on Certificates, they can modify the metadata of any certificates within the Keyfactor Command database. If the users have not been granted the global <i>Read</i> permission, they can only modify the certificates found in collections to which they

Portal Permis- sion	API Permission	Description
		have been granted collection-level <i>Read</i> access.
		Note: If you plan to edit metadata via the Keyfactor API, the user running the API needs only <i>Edit Metadata</i> permissions. <i>Read</i> permissions are not required.
Import	Certificates: Import  Users can import certificates using the Managemer Add Certificate page or the Keyfactor API POST /C tificates/Import method. Users who also have Read sions for Certificate Store Management or contained permissions can add certificates to certificate store Add Certificate.	
		Note: This permission cannot be applied at the certificate collection level.
Download with Private Key	Certificates: Recover	Users can download the certificates with their private key.
Revoke Certificates: Revo		Users can revoke certificates through Keyfactor Command. Users with this role can use the revoke certificate operation on any certificates to which they have been granted access. This includes certificates that have been issued by a Microsoft or EJBCA CA configured for synchronization or by a cloud-based certificate vendor that is managed via a Keyfactor certificate gateway.
		Important: In order to successfully revoke certificates, the service account under which the Keyfactor Command application pool is running must be granted "Issue and Manage Certificates" and "Manage CA" permissions to the CA database as per Create Active Directory Groups to Control Access to Keyfactor Command Features in the Keyfactor Command Server Installation Guide, or, if delegation is configured for the CA, the user executing the revoke must have the "Issue and Manage Certificates" permissions while the application pool service account has the "Manage CA" permissions. If

Portal Permission	API Permission	Description	
		you are using explicit credentials to authenticate your CA (see Adding or Modifying a CA Record on page 355), it is the user specified on the CA configuration in Keyfactor Command who must have permissions on the CA.	
Delete	Certificates: <i>Delete</i>	Users can delete certificates and, if applicable, the private keys of the certificates from the Keyfactor Command database.	
Import Private Key	Certificates: ImportPrivateKey	Users can save the private key for the certificate in the Keyfactor Command database.  Users with this role can add a certificate with an associated private key through the Add Certificate option under the Certificate Locations menu (see Add Certificate on page 74 and the private key will be stored in the Keyfactor Command database. Users must also be granted the <i>Import</i> role in ord to be able to use the Add Certificate feature.	
		Note: This permission cannot be applied at the certificate collection level.	

## Dashboard

Table 56: Dashboard Security Role Permissions v1

Portal Permis- sion	API Permission	Description
Read	Dashboard: Read	Users can view the panels on their personalized dashboard and add and remove them.
Risk Header	Dashboard: RiskHeader	Users can view the risk header at the top of the dashboard.

## **Event Handler Registration**

Table 57: Event Handler Registration Security Role Permissions v1

Portal Permis- sion	API Permission	Description
Read	EventHandlerRegistration: Read	Users can view the event handler registration settings.
Modify	EventHandlerRegistration:  Modify	Users can modify the event handler registration settings.

## **Identity Providers**

Table 58: Identity Providers Security Role Permissions v1

Portal Permission	API Permission	Description
Read	IdentityProviders: Read	Users can view the identity provider settings.
Modify	IdentityProviders: Modify	Users can modify the identity provider settings.

## Mac Auto-Enroll Management

Table 59: Mac Auto-Enroll Management Security Role Permissions v1

Portal Permis- sion	API Permission	Description
Read	MacAutoEnrollManagement: Read	Users can view the Mac Auto-Enroll Management settings.
Modify	MacAutoEnrollManagement:  Modify	Users can modify the Mac Auto-Enroll Management settings.

## **Management Portal**

Table 60: Management Portal Security Role Permissions v1

Portal Permission	API Permis- sion	Description
Read	AdminPortal: Read	Users can access the Management Portal. This permission must be enabled for all roles that will access the Management Portal.

# Monitoring

Table 61: Monitoring Security Role Permissions v1

Portal Permis- sion	API Permis- sion	Description
Read	Monitoring: Read	Users can view the expiration alerts in the Certificate Alerts in the Management Portal and the equivalent API functions, including the alert schedule.
Modify	Monitoring: <i>Modify</i>	Users can modify the expiration alerts, including the alert text, recipients and event handlers. Users can also add new alerts, delete alerts and configure the expiration alert delivery schedule.
Test	Monitoring: Test	Users can test the expiration alerts, including sending email to recipients. Users must also have Read permissions for Monitoring to access this in the Management Portal.

## **PKI Management**

Table 62: PKI Management Security Role Permissions v1

Portal Permis- sion	API Permission	Description
Read	PkiManagement: Read	Users can view PKI management settings within:  Certificate Authorities  Certificate Templates  Revocation Monitoring
Modify	PkiManagement:  Modify	Users can modify PKI management settings to:  Import, add, edit, and delete certificate authorities  Import and edit certificate templates  Add, edit, delete, and test revocation monitoring endpoints  Configure revocation monitoring schedules  Configure revocation monitoring recipients

# **Privileged Access Management**

Table 63: Privileged Access Management Security Role Permissions v1

Portal Permis- sion	API Permission	Description
Read	PrivilegedAccessManagement: Read	Users can view PAM providers.
Modify	PrivilegedAccessManagement:  Modify	Users can add, edit, and delete PAM providers.

## **Reports**

Table 64: Reports Security Role Permissions v1

Portal Permis- sion	API Permis- sion	Description	
Read	Reports: Read	Users can generate and view reports.	
Modify	Reports: Modify	Users can modify the delivery schedule for reports in Report Manager in the Management Portal and the equivalent API func- tions and add, edit, and delete custom reports.	
		Note: Report scheduling is limited by collection permissions. Users in roles that have <i>Reports: Read and Modify</i> permissions will also need to have <i>Read</i> collection permissions on individual collections to have the ability to add, edit, and delete schedules associated with collections. The user will not have access to add, edit, and delete schedules for any collections for which they do not have collection <i>Read</i> permissions in addition to <i>Reports</i> permissions.	

## **Scripts**

Table 65: Scripts Security Role Permissions v1

Portal Permission	API Permission	Description
Read	Scripts: Read	Users can view scripts.
Modify	Scripts: Modify	Users can add, edit, and delete scripts.

# **Security Settings**

Table 66: Security Settings Security Role Permissions v1

Portal Permis- sion	API Permission	Description
Read	SecuritySettings: Read	Users can view the settings for Security Roles and Security Claims. Users must also have the Read permission for System Settings to access this in the Management Portal.
Modify	SecuritySettings: Modify	Users can modify the settings for Security Roles and Security Claims.

## SSH

Table 67: SSH Security Role Permissions v1

Portal Permis- sion	API Permission	Description
User	SSH: User	Users can generate their own SSH keys.
Server Admin	SSH: ServerAdmin	Users can use all SSH functions, except creating server groups and assigning server group owners. Users have limited access to some functions based on server group ownership (see <a href="SSH Permissions on page 598">SSH Permissions on page 598</a> ).
Enterprise Admin	SSH: Enter- priseAdmin	Users can use all SSH functions (see <u>SSH Permissions on page 598</u> ).

## SSL Management

Table 68: SSL Management Security Role Permissions v1

Portal Permis- sion	API Permission	Description
Read	SslManagement: Read	Users can view the SSL Discovery pages in the Management Portal and the equivalent API functions, including defined networks and the network ranges configured for them, agent pools, and scan results. Users can use the query tool on the Results tab to find discovered endpoints and then view the discovered endpoints, including the details for the endpoints.
Modify	SslManagement:  Modify	Users can modify the SSL Discovery settings:  • Create, edit, and delete networks, including scan sched-

Portal Permis- sion	API Permission	Description
		ules and notification recipients  Add, edit, and delete network ranges for networks  Add, edit, and delete agent pools  Add and remove discovered endpoints from monitoring

## **System Settings**

Table 69: System Settings Security Role Permissions v1

Portal Permission	API Permission	Description
Read	SystemSettings: Read	Users can view the orchestrator auto-registration settings; users must also have <i>Read</i> permissions for Agent Management to access this in the Management Portal. Users can view the System Settings for:  • SMTP Configuration for email delivery of reports and alerts  • Installed components  • Licensing  • General Alerts and Warnings about the health of the Keyfactor Command system (not related to a specific area of the product)
Modify	SystemSettings:  Modify	Users can modify the System Settings for:  • Update SMTP Configuration for email delivery of reports and alerts  • Installed components, including removing servers from use  • Licensing, including the option to replace the existing license file

## **Workflow Definitions**

Table 70: Workflow Definitions Security Role Permissions v1

Portal Permis- sion	API Permission	Description
Read	WorkflowDefinitions: Read	Users can view the configured workflow definitions.
Modify	WorkflowDefinitions:	Users can modify both the built-in and any custom work-

Portal Permis- sion	API Permission	Description
	Modify	flow definitions, including the name and description and the configuration for the steps. Users can also add new workflow definitions, delete workflow definitions, publish workflow definitions, and import and export workflow definitions.

## **Workflow Instances**

Table 71: Workflow Instances Security Role Permissions v1

Portal Permis- sion	API Permission	Description
ReadAll	WorkflowInstances: ReadAll	Users can view all the workflow instances that have been initiated.
Read - Assigned To Me	WorkflowInstances: ReadAssignedToMe	Users can view the workflow instances that have been initiated and are awaiting input from them.
		Tip: There is not a security permission at this level that controls whether users can provide input (a signal) to a workflow instance. This is controlled using the security roles configured on the specific workflow definition. Any user who holds one of the roles configured in the workflow step that requires a signal may provide the necessary input. The user does not need to hold the Read - Assigned To Me Workflow Instances permission in order to provide the input.
Read - Started By Me	WorkflowInstances: ReadMy	Users can view the workflow instances that have been initiated by them (e.g. because they enrolled for a certificate).
Manage	WorkflowInstances: Manage	Users can manage initiated workflow instances, including stopping, restarting, and deleting them.

#### **Security Role Operations**

### Adding or Modifying a Security Role

**Tip**: The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Security > Modify

Security > Read

To add a new security role or update an existing role:

- 1. In the Management Portal, browse to System Settings Icon \* > Security Roles and Claims.
- 2. On the Security Roles and Claims page, select the Security Role tab and click **Add** from the menu at the top of the grid to add a new security role, or highlight a row and click **Edit** from the top of the grid or from the right click menu to modify an existing role.

**Note**: The Administrator and Reporting API Access roles cannot be edited or deleted—they are shown as *immutable* in the grid.

3. Either the **Add Security Role** dialog or **Role information For <role>** dialog will open. Fill in each tab of the dialog with the information desired for the selected security role as described below.

#### **Details Tab**

On the details tab, give the role a **Name** and **Description**. Both fields are required. In the **Permission Set** dropdown, select a permission set to apply to the role. For more information about permission sets, see *Permission Sets* in the *Keyfactor API Reference Guide*.

**Note**: Selecting a permission set limits the permissions available for selection in the dialog to those supported by the permission set. If you select a permission set other than the Global permission set, some permissions may not appear in the dialogs. This includes the Collection Permissions, Container Permissions and PAM Provider Permissions tabs, which only appear if the permissions for these are included in the selected permission set.

If you change the permission set for a role after permissions have already been granted for the role, any permissions not contained in the new permission set will be removed from the role upon save.

#### **Global Permissions Tab**

On the Global Permissions tab, check the boxes for the permissions that are appropriate for the new role (see Security Role Permissions on page 633).

## Security Roles and Claims 9

Role Information For: Power Users

Figure 349: Grant Global Permissions to a Security Role

Tip: If desired, use the dropdown at the top to enable all the **Read** boxes (*Read Only*) or **All** the boxes (*Select All*). Click **Apply** to apply the selection in the dropdown across all permissions. Click **Reset** to return the dialog to the state it was in when last saved and remove any changes made since opening the permissions for editing. Click **Clear** to uncheck all the boxes.

**Note:** For the most part, when you grant Modify role permissions to an area in the Management Portal, you must also grant Read role permissions to that same area for

that security role to receive full functionality. Granting Modify without Read to a user or a group can result in unexpected behavior. See also <u>Certificate Collection Permissions on page 628</u>.

**Note**: Security roles for SSH key management are structured somewhat differently than those for most of the rest of the product set, as they don't use the standard Read and Modify convention. For more information, see SSH Permissions on page 598.

#### **Collection Permissions Tab**

Optionally, on the Collection Permissions tab, highlight each certificate collection you would like to set permissions for and click the toggle button for each desired permission (see <u>Certificate Collection Permissions on page 628</u>). If you do not opt to set permissions on any collections, the permissions set on the Global Permissions tab will apply to all collections.

Along the top of the Collection Permissions tab, you can see the system-wide certificate collection permissions that have been configured. This is useful for reference. The system-wide settings may also be edited from this tab, if desired.

Any permissions that have been enabled at the system-wide level will not be available for configuration at the collection-level. Toggles for these will be grayed out.

**Tip:** The search bar at the top of Collection Name column on the collections tab can make it easier to find collections if you have a large number of them.

Figure 350: Grant Collection Permissions to a Security Role

#### **Container Permissions Tab**

Optionally, on the Container Permissions tab, highlight each certificate store container you would like to set permissions for and click the toggle button for each desired permission (see Container Permissions on page 630). If you do not opt to set permissions on any certificate store containers, the permissions set on the Global Permissions tab will apply to all certificate store containers.

**Tip:** The search bar at the top of Container Name column on the containers tab can make it easier to find certificate store containers if you have a large number of them.

Figure 351: Grant Container Permissions to a Security Role

#### **PAM Provider Permissions Tab**

Optionally, on the PAM Provider Permissions tab, highlight each PAM provider you would like to set permissions for and click the toggle button for each desired permission (see <u>PAM Permissions on page 632</u>). If you do not opt to set permissions on any PAM providers, the permissions set on the Global Permissions tab will apply to all PAM providers.

**Tip:** The search bar at the top of PAM Provider Name column on the PAM provider permissions tab can make it easier to find PAM providers if you have a large number of them.

#### Claims Tab

On the Claims tab, you associate security claims with the security role to grant the permissions associated with the role to claim owners. You can associate existing security claims or add new security claims and associate them in one step. Claim to role associations can also be removed from this tab, but claims cannot be deleted from here.

To add a new claim and associate it with the role in one step:

- a. On the Claims tab, click **Add New** from the menu at the top of the grid to add a new security claim and associate it.
- b. In the Add Claim dialog, select a Claim Type in the dropdown. Supported claim types are:
  - Active Directory User
     Active Directory user account.
  - · Active Directory Group
  - · Active Directory group.
  - Active Directory Computer
  - · Active Directory machine account.
  - OAuth Client Id

An open authorization client application claim.

OAuth Object Id

An open authorization claim of a type not covered by client, role or subject.

OAuth Role

An open authorization group claim.

OAuth Subject

An open authorization user claim.

c. In the Claim Value field, enter the identifying information for the entity specified in the claim. For Active Directory users and groups, this will be in the form DOMAIN\user or group name (e.g. KEYEXAMPLE\PKI Administrators). For Active Directory computers, this will be in the form of a machine account (e.g. KEYEXAMPLE\MyServer\$). For Keyfactor Identity Provider, users are referenced by GUID (see Configuring Keyfactor Identity Provider and Collection Data for the Keyfactor Command Installation in the Keyfactor Command Server Installation Guide) and groups (roles) are referenced by role name.

**Important:** The built-in Active Directory groups Domain Admins and Enterprise Admins cannot be used directly to grant access to the Management Portal due to how these groups function within Windows. You can create a custom Active Directory group, reference that group in the Management Portal, and add the built-in Domain Admins or Enterprise Admins group to that custom group, if desired.

**Tip:** If you're using a federated identity provider to authenticate your users, enter the Keyfactor Identity Provider identity for that user or a role in Keyfactor Identity

Provider that user has been granted (see Federating from Keyfactor Identity Provider in the Keyfactor Command Server Installation Guide).

d. In the **Provider** dropdown, select the correct identity provider for the claim—either Active Directory or the Keyfactor Identity Provider name you configured using the configuration wizard.

**Tip:** If you're using a federated identity provider to authenticate your users, select the Keyfactor Identity Provider name in the dropdown.

e. In the **Description** field, enter a description for the security claim. For example, the user's full name or the group owner. This field is required.

Figure 352: Add a Security Claim for a Keyfactor Identity Provider Role

To associate an existing claim with the role:

- a. On the Claims tab, highlight a row and click **Add Existing** from the top of the grid or from the right click menu to associate an existing claim.
- b. On the Select Existing Claims dialog, check the box next to each desired claim and click **Include** or **Include** and **Close** to associate the claim(s) with this role. You may use the search at the top of the dialog to limit the claims shown in the dialog grid (see <u>Using the Security Claim Search Feature on page 700</u>).

Figure 353: Associate Existing Claims with a Security Role

To remove the association of a claim to the role, on the Claims tab, highlight one or more rows and click **Remove** from the top of the grid or select a single row and choose **Remove** from the right click menu.

4. Click Save to save the role.

### Copying a Security Role

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Security > Modify

Security > Read

To copy a security role:

- 1. In the Management Portal, browse to System Settings Icon \*> Security Roles and Claims.
- 2. On the Security Roles and Claims page, select the Security Role tab. Highlight a row and click **Copy** from the top of the grid or from the right click menu to copy an existing role.
- 3. Click OK to the Confirm Operation message.

**Note**: Copying a security role will also assign the new role to all the same security claims as the original role.

4. The name will automatically be set to *Copy of (original role name)* with the same description as the original role. Update the name and description and click **Save**.

Note: The Administrators and Reporting API Access roles cannot be copied.

### **Deleting a Security Role**

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Security > Modify

Security > Read

To delete a security role:

- 1. In the Management Portal, browse to System Settings Icon \*> Security Roles and Claims.
- 2. On the Security Roles and Claims page, select the Security Role tab. Highlight a row and click **Delete** from the top of the grid or from the right click menu to delete an existing role.

Note: The Administrators and Reporting API Access roles cannot be edited or deleted.

**Tip:** You can view all the permissions set for a given role at a glance by granting *one* role to *one* claim only (and no other roles) and then using the View Permissions option for the claim (see Viewing Permissions for a Security Claim on page 697).

### **Using the Security Role Search Feature**

**Note**: The security role search skips the validation check when loading for improved performance. The validation still occurs when loading a single record, so users will encounter an error when trying to work with an invalid role.

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an *is null* or *is not null* comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

Each query consists of three parts:

### **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

Name	ClaimProviderName
Complete or partial matches with the name of the security role.	Complete or partial matches with the name of the claim provider (e.g. Active Directory) for claims associated with the roles.

### Comparison Operator

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

•	Is equal to (-eq)	•	Starts with (-startswith)		
•	Is not equal to (-ne)	•	Ends with (-endswith)		
•	Contains (-contains)	•	Is null (-eq NULL)		
•	Does not contain (-notcontains)	•	Is not null (-ne NULL)		
Most date and integer fields support:					

M

• Is equal to (-eq)	<ul> <li>Is greater than (-gt)</li> </ul>					
• Is not equal to (-ne)	• Is greater than or equal to (-ge)					
• Is less than (-It)	• Is null (-eq NULL)					
• Is less than or equal to (-le)	<ul> <li>Is not null (-ne NULL)</li> </ul>					
Most Boolean (true/false) fields support:						

•	Is equal to (-eq)	•	Is null (-eq NULL)
•	Is not equal to (-ne)	•	Is not null (-ne NULL)

### **Comparison Value**

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

· Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.

• Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

#### Advanced Searches

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

#### Multiple Criteria

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click **Insert** to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

### **Security Claim Operations**

From the *Claims* tab of the Security Roles and Claims page in Keyfactor Command you can create the individual claims that will be associated with one or more security roles to define the user access to Keyfactor Command. Prior to adding new claims, it is recommended that you create all of the security roles you require (see <u>Security Role Operations on page 685</u>) so they can be assigned to the new claims.

**Tip:** To associate a security claim with a role, edit the desired security role, and select claims on the Claims tab (see Claims Tab on page 688).

### Adding or Modifying Security Claims

Security claims can be added on the Security Roles and Claims page Claims tab and also from the Claims tab within each role when editing roles on the Security Roles and Claims page Roles tab.

Tip: The following permissions (see Security Roles and Claims in the Keyfactor Command Reference Guide) are required to use this feature:

Security > Read

Security > Modify

To add a new security claim or update an existing claim:

- 1. In the Management Portal, browse to System Settings Icon \*> Security Roles and Claims.
- 2. On the Security Roles and Claims page, select the Claims tab and click Add from the menu at the top of the grid to add a new security claim, or highlight a row and click Edit from the top of the grid or from the right click menu to modify an existing claim.
- 3. In the Add/Edit Claim dialog, select a Claim Type in the dropdown. Supported claim types are:
  - · Active Directory User
    - Active Directory user account.
  - Active Directory Group
  - Active Directory group.
  - · Active Directory Computer
  - · Active Directory machine account.
  - OAuth Client Id
    - An open authorization client application claim.
  - · OAuth Object Id
    - An open authorization claim of a type not covered by client, role or subject.
  - OAuth Role
    - An open authorization group claim.
  - · OAuth Subject
    - An open authorization user claim.

Note: This field cannot be modified on an edit.

4. In the Claim Value field, enter the identifying information for the entity specified in the claim. For Active Directory users and groups, this will be in the form DOMAIN\user or group name (e.g. KEYEXAMPLE\PKI Administrators). For Active Directory computers, this will be in the form of a machine account (e.g. KEYEXAMPLE\MyServer\$). For Keyfactor Identity Provider, users are referenced by GUID (see Configuring Keyfactor Identity Provider and Collection Data for the Keyfactor Command Installation in the Keyfactor Command Server Installation Guide) and groups (roles) are referenced by role name.

Important: The built-in Active Directory groups Domain Admins and Enterprise Admins cannot be used directly to grant access to the Management Portal due to how these groups function within Windows. You can create a custom Active Directory group, reference that group in the Management Portal, and add the built-in Domain Admins or Enterprise Admins group to that custom group, if desired.

Tip: If you're using a federated identity provider to authenticate your users, enter the Keyfactor Identity Provider identity for that user or a role in Keyfactor Identity Provider that user has been granted (see Federating from Keyfactor Identity Provider in the Keyfactor Command Server Installation Guide).

Note: This field cannot be modified on an edit.

5. In the Provider dropdown, select the correct identity provider for the claim-either Active Directory or the Keyfactor Identity Provider name you configured using the configuration wizard.

Tip: If you're using a federated identity provider to authenticate your users, select the Keyfactor Identity Provider name in the dropdown.

Note: This field cannot be modified on an edit.

6. In the Description field, enter a description for the security claim. For example, the user's full name or the group owner. This field is required.

Figure 354: Add a Security Claim for a Keyfactor Identity Provider Role

### **Deleting a Security Claim**

**Tip**: The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Security > Read

Security > Modify

To delete a security claim:

- 1. In the Management Portal, browse to System Settings Icon \*> Security Roles and Claims.
- 2. Select the **Claims tab** of the page. Highlight the claim you want to delete and click **Delete** at the top of the grid. Or right-click the row in the grid and choose **Delete** from the right-click menu.

**Important:** Do not delete the last claim associated with the Administrator role or you will lose access to the administrative features of the Management Portal.

### Viewing Permissions for a Security Claim

Within this dialog you can view the global permissions for the claim, certificate store container permissions, or certificate collection permissions.

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature: Security > Read

- 1. In the Management Portal, browse to System Settings Icon \*> Security Roles and Claims.
- 2. Select the **Claims tab** of the page. Highlight the claim you want to view permissions for and click **View Permissions** at the top of the grid. Or right-click the row in the grid and choose **View Permissions** from the right-click menu.

**Note**: The **Global Permissions** tab of the *View Permissions* dialog will be updated in a future release to match the new Keyfactor Command v11 security structure. Currently it is showing the old structure which is not a one-to-one match to the v11 structure. The other tabs are upto-date and accurate.

If the user or group has been granted more than one role, you see the permissions of all the roles granted to the user or group consolidated together on the **View Permissions** dialog for easy viewing. Hover over a specific permission to see how that permission was granted.

Figure 355: View Global Permissions for a Security Claim

Figure 356: Collection Permissions for a Security Claim

Figure 357: Container Permissions for a Security Claim

## Viewing Roles for a Security Claim

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature: Security > Read

To view the roles associated with a claim:

- 1. In the Management Portal, browse to System Settings Icon \*> Security Roles and Claims.
- Select the Claims tab of the page. Highlight the claim you want to view roles for and click View Roles at the top of the grid. Or right-click the row in the grid and choose View Roles from the right-click menu.

Figure 358: View Roles associated with a Security Claim

### Using the Security Claim Search Feature

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an *is null* or *is not null* comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

Each query consists of three parts:

## **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

#### **ADClaimValue**

Complete matches with the name of the security claim for Active Directory (e.g. KEYEXAMPLE\Keyfactor Administrators).

#### ClaimType

The claim type matches or doesn't match the referenced value. Supported claim types are:

- Computer
- Group
- User
- OAuthClientId
- OAuthOid
- OAuthRole
- OAuthSubject

#### ClaimValue

Complete or partial matches with the name of the security claim for OAuth providers (e.g. Keyfactor Administrators).

#### Description

Complete or partial matches with the description for the security claim.

## **Comparison Operator**

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Contains (-contains)
- Does not contain (-notcontains)
- Most date and integer fields support:
- Is equal to (-eq)
- Is not equal to (-ne)
- Is less than (-It)
- Is less than or equal to (-le)
- Most Boolean (true/false) fields support:
- Is equal to (-eq)
- Is not equal to (-ne)

- Starts with (-startswith)
- Ends with (-endswith)
- Is null (-eq NULL)
- Is not null (-ne NULL)
- Is greater than (-gt)
- Is greater than or equal to (-ge)
- Is null (-eq NULL)
- Is not null (-ne NULL)
- Is null (-eq NULL)
- Is not null (-ne NULL)

### **Comparison Value**

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

- Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.
- Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

#### **Advanced Searches**

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

#### **Multiple Criteria**

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click **Insert** to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

### 2.1.11.3 Certificate Store Types

Certificate store types allow you to define types of locations to contain certificates. These locations can be defined for operations such as inventory, management, discovery, and reenrollment.

Custom certificate store types can be created for use with custom extensions (see <u>Certificate Store</u> Type Operations on the next page).

Tip: Click the help icon (3) next to the page title to open the embedded web copy of the Keyfactor Command Documentation Suite to this section.

You can also find the help icon at the top of the page next to the Log Out button. From here you can choose to open either the Keyfactor Command Documentation Suite at the home page or the Keyfactor API Endpoint Utility.

### **Certificate Store Type Operations**

Certificate store types define locations against which Keyfactor Command can perform predefined operations. New ones are commonly added for custom orchestrators created with the Keyfactor AnyAgent, the Keyfactor Native Agent, or another of the tools in the Keyfactor Integration SDK (see Orchestrators on page 482).

The certificate store types page displays a list of the currently defined types and offers the options to create new types, edit existing types and delete types. It is not possible to update built-in certificate store types because doing so will break the associated orchestrator functionality.

## Certificate Store Types 9

Use this page to configure the platforms that store and use certificates that will be managed with a Keyfactor Orchestrator

Figure 359: Certificate Store Types

### Adding or Editing a Certificate Store Type

Tip: The following permissions (see Security Roles and Claims in the Keyfactor Command Reference Guide) are required to use this feature:

Certificate Stores > Modify Certificate Stores > Read

Note: Certificate store types can only be updated in a very limited way if they are actively in use (there are any certificate stores defined for them). Updates to the Name and Short Name

are supported in this case as are additions to the Supported Job Types, but no other updates can be saved.

To create or modify a certificate store type:

- 1. In the Management Portal, browse to System Settings Icon ❖ > Certificate Store Types.
- 2. On the Certificate Store Types page, click **Add** to create a new certificate store type, or click **Edit** from either the top or right-click menu to modify an existing one.
- 3. In the Certificate Store Types dialog, you will see four tabs. Complete the dialog with appropriate information using the following information:

### **Basic Tab**

Figure 360: Add New Certificate Store Type: Basic Tab

- Name: Enter a user friendly recognizable name for the certificate store type.
- Short Name: Enter a short name identifier for the certificate store type. This value is used by the Keyfactor Universal Orchestrator installation and configuration tools to validate the orchestrator capabilities.
- Custom Capability: If desired, check this box to allow you to define a custom capability name. By default, the Short Name is used as the capability name, and in most cases a separate capability name is not needed. The capability name you set here corresponds to configurations made in the manifest.json file for your custom orchestrator extension.

**Tip:** This box shows as checked only if the value entered in the *Custom Capability* does not match the value entered in the *Short Name*. If you check the box, enter a value that matches the short name value, save the record and open it again, the box will show unchecked and the *Custom Capability* field will show empty since the value matches the *Short Name* value.

**Note**: The *Custom Capability* cannot be changed on an edit if an orchestrator has registered with Keyfactor Command, been approved, and included the certificate store type in its capability list. If you change the *Short Name* in this circumstance, the *Custom Capability* box will be checked and the value set to the original value of the *Short Name*.

#### Supported Job Types

Select the job capabilities required to support the store type.

- Inventory: Determine what is in the certificate store(s) and report the contents to Keyfactor Command. This capability is required for all store types.
- Add: Add new certificates to a certificate store.
- Remove: Remove certificates from a certificate store.
- Create: Create a new certificate store.
- Discovery: Determine what certificate stores of this type are on the device.
- Reenrollment: Generate a keypair on the device and submit a certificate signing request using on-device key generation (ODKG).

#### General Settings

 Needs Server: Select if server access is required for adding certificate stores to the certificate store type. If selected, a user will be prompted for a username and password to connect to the remote server.

- Blueprint Allowed: Select whether certificate stores of this type will be included when creating or applying blueprints. For more details, see <u>Generating and</u> Applying Blueprints on page 502.
- Uses PowerShell: Select if the jobs for this store type are implemented by Power-Shell instead of a .NET class.

### Password Settings

- Requires Store Password: Select to mandate that a password be entered and authenticated when creating stores of this type. This password secures the store as a whole.
- Supports Entry Password: Select to allow an entry password to be entered and authenticated when adding a certificate to a store. This password secures a single certificate within the store.

### **Advanced Tab**

Figure 361: Add New Certificate Store Type: Advanced Tab

#### Store Path Type:

- Freeform: Select if users are required to enter a path defining the store location.
- Fixed: Select if a store path does not apply, generally one store per device (e.g. IIS).
- Multiple Choice: Select to allow users to select an option during certificate store creation.

If Store Path Type is Fixed or Multiple Choice, a value should be provided in the value field. For multiple choice, this should be a comma separated list of values that users will be able to select from when defining a certificate store location.

## Other Settings

#### Supports Custom Alias:

Forbidden: Select if a custom alias is not required.

**Note**: If this is set to **Forbidden**, the **Alias** field will not display on the Add to Certificate Store page unless *Overwrite* is checked on the page.

- Optional: Select if the custom alias is optional.
- Required: Select if the custom alias is required.

#### Private Key Handling:

- Forbidden: Select if a private key is not required; generally, applies to trust stores (e.g. Root CA certificates).
- Optional: Select if the private key is optional; applies to store types that could represent either a Trust Store or End-Entity Store.
- Required: Select if the private key is required; applies to stores that hold an End-Entity Certificate (server or client authorization).

#### PFX Password Style:

- **Default:** Opt to have Keyfactor Command randomly generate a password.
- Custom: Opt to allow a password to be entered and authenticated when enrolling a certificate through the Keyfactor Command Management Portal when installing a store of this type. The Custom option can be selected only if Allow Custom Password in the Application Settings is equal to *True*. For more details, see Application Settings: Enrollment Tab on page 610.

#### **Custom Fields Tab**

Custom fields define unique properties for the given certificate store type. Click **Add** on this tab to open the Add Custom Field dialog box.

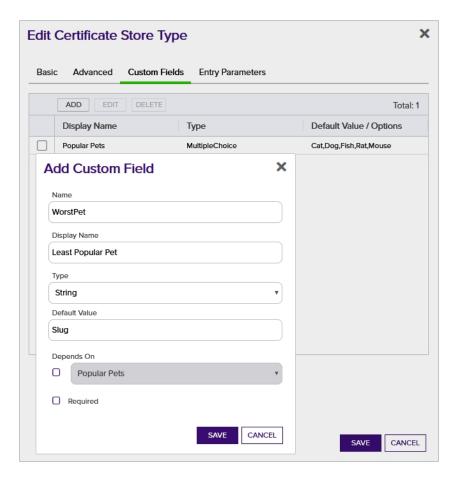

Figure 362: Add New Certificate Store Type: Custom Fields Tab

- Name: Enter the name submitted to the orchestrator and referenced in the extension module custom code.
- Display Name: Enter a user-friendly recognizable name.
- **Type:** Select whether parameter information is stored as a string, Boolean, multiple choice or secret.

Note: This field cannot be modified on an edit.

Default Value / Multiple Choice Options: Add a default value that will pre-populate the
parameter field in the Add New Certificate Store dialog box. If you select a type of
Multiple Choice, populate this field with a comma-separated list of multiple choice options
for this parameter. If you select a type of Boolean, you will be given the option of True or
False here.

- Depends On: Check this box if you have another custom field for this certificate store
  type and want to create a relationship between that one and this one. Then select the
  custom field on which this custom field depends in the dropdown. This option configures
  one custom field to display in the certificate store configuration dialog only if another
  custom field contains a value.
- Required: Select whether a value for this parameter must be entered before a certificate store can be added to Keyfactor Command.

## **Entry Parameters Tab**

Entry parameters define unique properties that are required when performing management jobs on a certificate store of this type. Click **Add** on this tab to open the Add Entry Parameter dialog box.

Tip: What's the difference between custom fields and entry parameters?

- Custom fields are about the certificate store definition itself and are static. For example, you might use a custom field to define the primary node name of an F5 instance. This node name is the same no matter what inventory or management jobs you do with the F5 device(s). Values for custom fields are entered in the certificate store record when creating or editing the certificate store record.
- Entry parameters are about the specific certificate within the certificate store. They are used to send additional information related to the certificate to the server or device that hosts the certificate store when running management jobs for that certificate store. Often this is more fluid information that isn't the same for every use of that certificate store. For example, several virtual servers with separate certificates in the same folder may exist on a NetScaler device. When replacing one certificate, updates may need to be made to only the virtual server that is using the certificate. In this case, the authorized user will be prompted to enter the virtual server name based on an entry parameter. Values for entry parameters are entered at the time a management job is initiated (e.g. adding a certificate to a certificate store).

Figure 363: Add New Certificate Store Type: Entry Parameters Tab

- Name: Enter the name for the entry parameter. This value must be unique.
- Display Name: Enter a user-friendly recognizable name. This value must be unique.
- **Type:** Select whether parameter information is stored as a string, Boolean, multiple choice or secret.

Note: This field cannot be modified on an edit.

- **Default Value**: Add a default value that will pre-populate the parameter field in the *Add New Certificate Store* dialog box. If you select a type of Boolean, you will be given the option of True, False, or Not Set here.
- Multiple Choice Options: Populate this field with a comma-separated list of multiple choice options if you selected a *Type* of multiple choice. This field will be grayed out if you selected a *Type* other than multiple choice.
- **Depends On:** Check this box if you have another entry parameter for this certificate store type and want to create a relationship between that one and this one. Then select the entry parameter on which this entry parameter depends in the dropdown. This option configures one entry parameter to display in the certificate store configuration dialog only if another entry parameter contains a value.

#### · Required When:

- Entry has a private key: If set to true, a value must be provided for this field when configuring a management job (either add or remove) if the certificate has an associated private key in Keyfactor Command. This would be the case, for example, when doing a PFX enrollment and adding the resulting certificate to a certificate store.
- Adding an entry: If set to true, a value must be provided for this field when configuring an add certificate job.
- **Removing an entry**: If set to *true*, a value must be provided for this field when configuring a remove certificate job.
- Reenrolling an entry: If set to true, a value must be provided for this field when configuring a reenrollment job.
- 4. Click **Save** to save the new certificate store type.

Note: Built-in certificate store types cannot be edited.

## **Deleting a Certificate Store Type**

You may delete one store type at a time.

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

Certificate Stores > Modify

Certificate Stores > Read

To delete a certificate store type:

- 1. In the Management Portal, browse to System Settings Icon \*> Certificate Store Types.
- 2. On the Certificate Store Types page, highlight the row in the grid of the certificate store type to delete and click **Delete** at the top of the grid or right-click the type in the grid and choose

**Delete** from the right-click menu.

3. On the Confirm Operation alert, click **OK** to confirm or **Cancel** to cancel the operation.

#### 2.1.11.4 Certificate Metadata

Using user-defined certificate metadata you can tag certificates with additional information you want to assign to certificates at the point of enrollment, such as points of contact or certificate/app owners. Metadata fields can be defined as being required or optional during enrollment. The data from the metadata fields can then be used for queries and alerts in the Management Portal.

First, you must add all the metadata fields you will use across the platform via System Settings Icon 🌣 > Certificate Metadata (see Metadata Field Operations below). These system-wide settings will then become the default metadata settings for all templates and they will be assigned to certificates during enrollment via the selected template. You may choose to modify the system-wide metadata field(s) for specific templates by creating template-specific metadata settings. See Certificate Template Operations on page 382 and Enrollment on page 135 for more information.

Tip: Click the help icon (3) next to the page title to open the embedded web copy of the Keyfactor Command Documentation Suite to this section.

You can also find the help icon at the top of the page next to the **Log Out** button. From here you can choose to open either the Keyfactor Command Documentation Suite at the home page or the Keyfactor API Endpoint Utility.

## **Metadata Field Operations**

To select a single row in the certificate metadata field grid, click to highlight it and then select an operation from either the top of the grid or the right-click menu.

Tip: The following permissions (see Security Roles and Claims in the Keyfactor Command Reference Guide) are required to use this feature:

Metadata > Types > Read

Metadata > Types > Modify

# Adding or Modifying a Metadata Field

To create a new metadata field or edit an existing one:

- 1. In the Management Portal, browse to the System Settings Icon > Certificate Metadata.
- 2. On the Certificate Metadata page, click Add to create a new metadata field, or, to edit an existing one, double-click the row in the metadata grid, right-click the row and choose Edit from the right-click menu, or highlight the row in the grid and click **Edit** at the top of the grid.

#### Certificate Metadata 9

Certificate Metadata Types define additional fields that can be associated with Certificates to further identify them. These fields may then be used in Certificate Collections to create logical groupings.

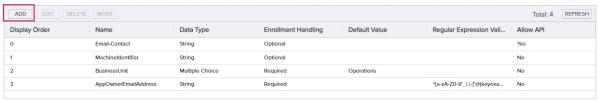

Figure 364: Certificate Metadata

3. In the Metadata Edit dialog, enter a Name for your metadata field. This name appears in interfaces where you can use metadata, such as certificate details dialogs, alert dialogs, certificate imports and certificate requests. Once this field has a value associated with it for at least one certificate, you cannot change this name. The metadata name field cannot contain spaces; dashes and underscores are supported.

**Important:** Be sure to review the list of existing queryable certificate fields on the <u>Certificate Search Page on page 35</u> before adding a new metadata field, so you do not add a field of the same name or alias as an existing field. Doing so would cause a search or alert on that field to fail. For example, do not create a metadata field called *NetBIOSRequester* or its alias *RequesterName*, as this would match is an existing certificate field, and having a metadata field with this name would create issues.

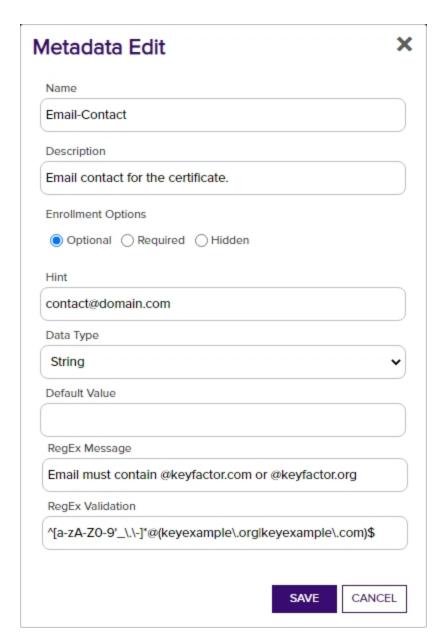

Figure 365: Create or Edit Certificate Metadata Field

- 4. Enter a **Description** for the metadata field.
- 5. The **Enrollment Options** provide three possible settings for the metadata field:
  - Select the **Optional** radio button to allow users the option to either enter a value or not enter a value in the field when populating metadata fields.

- Select the **Required** radio button to force users to enter a value in the field when populating metadata fields. Required fields will be marked with \*Required next to the field label on the Certificate Details dialog for a certificate and on the certificate enrollment pages.
- To hide the field on the enrollment pages (see <u>Enrollment on page 135</u>), select the **Hidden** radio button. Selecting the **Hidden** option does not hide the field in the certificate details (see <u>Metadata Tab on page 21</u>) or on the Add Certificate page (see <u>Add Certificate on page 74</u>).
- 6. Enter a short hint in the **Hint** field. This hint appears in unpopulated metadata string, integer, big text and date fields on editing interfaces to provide the user with a clue as to what type of data should be entered in the field.

**Note**: The Hint field is not used for some selections of the Data Type field (see the next step) and will disappear from the screen if a Data Type that does not use a Hint is selected.

Figure 366: Metadata Hints in a Certificate Details Dialog

7. Select the **Data Type** for the field in the dropdown. The available field types are String (alphanumeric), Integer (whole numbers), Date, Multiple Choice, Big Text, and Boolean (True/False). String fields are limited to 400 characters. Big text fields are limited to 4000 characters. String fields support additional indexing, and so may be preferable for large databases where possible. The data type cannot be edited if the metadata field is associated with any certificate values.

The remaining fields on the dialog—plus the *Hint*—will vary depending on the data type selected. <u>Table 72: Certificate Metadata Data Type Dialog Options</u> shows the fields that appear based on the data type selected.

Table 72: Certificate Metadata Data Type Dialog Options

Data Type	Character Limit	Hint	Default Value	RegEx Message	RegEx Validation	Options
String	400 alpha- numeric with indexing	1	1	1	1	
Integer		1	1			
Date		1				
Boolean			1			
Multiple Choice	4,000		1			<b>✓</b>
Big Text	4000	1				

- 8. To set a default value with which to pre-populate the metadata field for new certificate requests made using the Management Portal enrollment pages, enter the desired value in the **Default Value** box, or, for Boolean fields, select the desired radio button. The default value option appears for string, integer, Boolean and multiple choice fields.
- 9. For string fields, you can choose to enter a regular expression against which entered data will be validated in the RegEx Validation field. When a user enters information in a metadata field that does not match the specified regular expression, he or she will see the warning message specified in the RegEx Message field. The example regular expression shown in Figure 365: Create or Edit Certificate Metadata Field is:

$$^[a-zA-Z0-9'_\.\-]*@(keyexample\.org|keyexample\.com)$$$

This regular expression specifies that the data entered in the field must consist of some number of characters prior to the @ made up only of lowercase letters, uppercase letters, numbers, apostrophes, underscores, periods, and/or hyphens followed by exactly either @keyexample.org or keyexample.com. For more examples of regular expressions, see Regular Expressions on page 403.

10. For multiple choice fields, enter the series of values that should appear in the field dropdown as a comma delimited list in the **Options** field.

For example:

**Note:** The multiple choice options are displayed in the order entered in the comma delimited list. When a user selects a multiple choice value in a metadata field while editing a certificate, the value is saved to the database as the string (e.g. Marketing). Subsequently editing the series of values for the metadata field or rearranging them will not affect existing certificates configured with values for this field.

11. Click Save to save your metadata field.

# **Sorting Metadata Fields**

You may change the display order for metadata fields. This affects how the fields display on the certificate details, certificate template details when configuring the metadata tab, and on enrollment pages.

To change the display order of a metadata field:

- 1. Browse to System Settings Icon ❖ > Certificate Metadata.
- 2. Right-click a grid row and choose **Move** from the right-click menu, or highlight the row in the grid and click **Move** at the top of the grid.
- 3. In the Display Order dialog enter the desired display order number and click Save. The value entered must fall without the current display order range. For example, if the current range is 0-12, enter 12 to move a field to the end of the list, not 13. The metadata field will move to the entered display order row and the metadata fields from the rows above and below will be reordered.

Figure 367: Metadata Display Order

## Deleting a Metadata Field

Metadata fields cannot be deleted if they are associated with any certificate values.

To delete a metadata field:

- 1. Browse to System Settings Icon ❖ > Certificate Metadata.
- 2. Right-click a grid row and choose **Delete** from the right-click menu, or highlight the row in the grid and click **Delete** at the top of the grid.

#### 2.1.11.5 Audit Log

PKI is more than Keyfactor Command, CAs, and certificates. It also includes the people and polices that interact with these entities. It is therefore critical to track the actions taken within Keyfactor Command that enable management of all entities that make up a PKI, as most attack vectors are only exposed internally. The Keyfactor Command audit logs are an immutable record of all changes made to the state of the application.

The information collected in the audit logs is available for viewing and analysis by several means:

- The data is available for viewing within the Keyfactor Command Management Portal, where a search tool may be used to search for specific logs (see <u>Using the Audit Log Search Feature on the next page</u>).
- The data is output to text-based logs on the Keyfactor Command server and stored for 14 days, by default (see <u>Log Monitoring on page 794</u>). From here, the logs may be collected by a centralized logging solution for analysis.
- The data is output to the Windows event log on the Keyfactor Command server in the Windows application event log. From here, the logs may be collected by a centralized logging solution for analysis. See <a href="Keyfactor Command Windows Event IDs on page 806">Keyfactor Command Windows Event IDs on page 806</a>. When analyzing audit logs as written to the Windows event log, it can be helpful to have the translations for the operation codes handy (see <a href="Audit Log Reference Codes on page 729">Audit log failures</a> (when Keyfactor Command fails to log to the audit log) are also logged to the Windows event log.
- The data may optionally be copied in real time to a separate server for analysis with a centralized logging solution (e.g. rsyslog, Logstash). For more information, see <u>Audit Log Output to a Cent-</u> ralized Logging Solution on page 805.

Any activity that triggers an audit flag generates an audit record. Auditable activities include actions (e.g. creation, change, deletion) on records in Keyfactor Command that have been configured as auditable (e.g. Certificates, Security, Templates, Application Settings). For a complete list of Keyfactor Command activity that is tracked through the audit log, see <a href="Audit Log Reference Codes">Audit Log Reference Codes</a> on page 729.

The audit log page in the Keyfactor Command Management Portal allows you to view all the audit logs stored in Keyfactor Command and perform searches on them. Audit logs are stored for seven years, by default (see Application Settings: Auditing Tab on page 609).

The audit log grid includes these fields:

- Level
   The logging level of the message. Most messages are generated at Information level.
- Category
   The area of Keyfactor Command that generated the audit log (see <u>Audit Log Categories on page 731</u>).
- Message
   The audit log message. The message is made up of the user who took the auditable action, the action the user took, the category the user acted upon, and the name of the object acted upon.
- Timestamp
   The time and date that the message was generated.

The grid can be sorted by clicking on a column header. All columns except Message may be sorted. Click the column header again to reverse the sort order. The grid columns can be arranged in any order desired by click-holding and dragging the header of the column you wish to move. The column widths may be adjusted by click-holding and dragging the line separating two column headers.

## Audit Log 9

View portal actions and logs for auditing. Clicking "Advanced" allows you to build a query based on multiple criteria using AND/OR logic. Select a field and comparison operator in the drop-downs and then enter a comparison value. Click "Insert" to add the search criteria to the query field below the selection fields. Each time you click the "Insert" button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

Figure 368: Audit Log

Tip: Click the help icon (3) next to the page title to open the embedded web copy of the Keyfactor Command Documentation Suite to this section.

You can also find the help icon at the top of the page next to the Log Out button. From here you can choose to open either the Keyfactor Command Documentation Suite at the home page or the Keyfactor API Endpoint Utility.

# Using the Audit Log Search Feature

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an is null or is not null comparison operator, the value field will be grayed out. Click the Search button to execute the query.

Each query consists of three parts:

# **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

**ActingUser** Name The user who performed the audited action, in the format DOMAIN\username for Active Directory authentication or just the username for Keyfactor Identity Provider. For actions initiated by the Keyfactor Command Service, this will be *Timer Service*. Supports the %ME% token (see Advanced Searches on page 722).

#### Level

The logging level of the message:

- Information
   A successful operation that changes the state of the data in the application
- Warning
   Notification of a possible malicious access attempt (e.g. an unauthorized user attempting to access a web page)
- Failure
   Notification that a user was denied access to an activity (this can be used to alert to a possible internal role security issue)

#### Timestamp

The time at which an action took place. Supports the %TODAY% token (see <u>Advanced Searches on page 722</u>).

## Category

The area of the product in which the auditable activity occurred. This list is built dynamically to show only those categories that are actually in your audit log. Select a category (e.g. Template) and for most categories an optional subsearch

The name of the object being audited. The name of the object is related to the category of auditable activity. If the category is template, the name will be the template name. If the category is SSH user, the name will be the username of the user owning the SSH key. If the category is expiration alert, the name will be the expiration alert name. Some category to name relationships are more clear than others.

For example, in the following audit message for a certificate enrollment, the name is the DN of the certificate:

The user 'KEYEXAMPLE\ggant' Created Certificate, 'CN=appsrvr12.keyexample.com,L=Chicago,ST=IL,C=US'

In the following workflow instance message, the name is the entire title of the workflow instance:

The User 'KEYEXAMPLE\mjones' Completed Workflow Instance, 'KEYEXAMPLE\mjones is enrolling for a certificate with CN=websrvr12.keyexample.com.'

In the following certificate collection message, the name is the name of the certificate collection that was created:

The user 'KEYEXAMPLE\jsmith' Created Certificate Query, 'Revoked Certs'

When you open the details for an audit log record, the name appears at the top of the details dialog as the second part of the dialog title (see <u>View</u>: <u>Audit Log Details on page 725</u>).

#### Operation

The type of operation performed. See <u>Audit Log Operations on</u> page 729 for a complete list of the available operations.

field (e.g. Template Defaults for templates) to find entries related to that category and optional subsearch field (e.g. any changes made to template default settings). See <u>Audit Log Categories on page 731</u> for a complete list of possible categories.

# **Comparison Operator**

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

- Is equal to (-eq)
- Is not equal to (-ne)
- Contains (-contains)
- Does not contain (-notcontains)
- Most date and integer fields support:
- Is equal to (-eq)
- Is not equal to (-ne)
- Is less than (-lt)
- Is less than or equal to (-le)
- Most Boolean (true/false) fields support:
- Is equal to (-eq)
- Is not equal to (-ne)

- Starts with (-startswith)
- Ends with (-endswith)
- Is null (-eq NULL)
- Is not null (-ne NULL)
- Is greater than (-gt)
- Is greater than or equal to (-ge)
- Is null (-eq NULL)
- Is not null (-ne NULL)
- Is null (-eq NULL)
- Is not null (-ne NULL)

## Comparison Value

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

 Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field. • Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

**Tip:** The *Message* field in the audit log grid is built from the *Acting User*, *Operation*, *Category*, and *Name* fields and is not searchable as the Message. Instead, search by Acting User, Operation, Category, and/or Name.

When you select Category in the query field, a fourth dropdown will appear. This *Property Field* allows you to further refine the search. The options available in this field vary depending on the selection made in the comparison value. Select *Any* to display all of the results for the selected category search combination. Select a specific value in the property field to display all the audit records that had changes to the selected field.

#### **Advanced Searches**

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

#### **Multiple Criteria**

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click **Insert** to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

In addition to the options available in the query builder, three special values can be used in selected searches by typing them in directly:

- %TODAY%
  - Use the TODAY special value in place of a specific date in date queries. This option supports math operations, so you can use TODAY-10 or TODAY+30. The built-in *Certificates Expiring in 7 Days* collection uses this special value (see Certificate Collection Manager on page 85).
- %ME%
   Use the ME special value in place of a specific domain\user name in queries that match a domain\user name. The built-in My Certificates collection uses this special value (see Certificate Collection Manager on page 85).
- %ME-AN%
   Use the ME-AN special value in place of a specific user name excluding the domain. This is beneficial in environments with multiple domains where there is a desire to query for a user's certificates even if they were requested across multiple domains.

**Important:** The special query options of %TODAY%, %ME%, and %ME-AN% are only supported in uppercase. Lowercase equivalents (e.g. %me%) cannot be substituted.

## **Audit Log Operations**

The audit log page in the Keyfactor Command Management Portal allows you to perform searches for all the audit logs stored in Keyfactor Command, view details for them, validate that they have not been tampered with, and output selections of them in CSV format.

## **Download CSV**

Click the **Download CSV** button at the top of the audit log grid to generate and download a commadelimited CSV file containing all audit log records per the search criteria applied to the grid. The CSV file will contain the information shown in <u>Table 73: Audit Download CSV Records</u> for each exported record.

Table 73: Audit Download CSV Records

Field	Description	
ld	Sequential Internal reference number	

Field	Description
Timestamp The date and time the auditable change was made.	
Message	The message displayed on the audit log grid. This field contains a human-readable summary of the change and is made up of the user who took the auditable action, the action the user took, the category the user acted upon, and the name of the object acted upon.
Operation	The operation type (e.g. Created, Updated, Deleted). For a list of possible operations, see <a href="Audit Log Operations on page 729">Audit Log Operations on page 729</a> .
Level	The logging level of the message (e.g. Info, Warning). Most messages are generated at Information level.
User	The user taking the action that generated that audit log, generally in DOMAIN\user-name format, though for actions initiated by the Keyfactor Command Service, this will be <i>Timer Service</i> .
Category  The area of the product in which the change was made (e.g. Certificates, Ter Application Settings) as per the available values in the <i>category</i> field in the a For a list of possible categories, see <a href="Audit Log Categories on page 731">Audit Log Categories on page 731</a> .	
Name	The specific object the action was taken on (e.g. the template name for a template change or the application setting name for an application setting change).
XMLMessage	The details of the change that was made in XML format. This field contains both the before state and the after state where applicable (e.g. an application setting that was configured as <i>true</i> before the change and <i>false</i> after the change). For example, this entry indicates that a change was made to the key retention policy (the template name the change was made to is specified in the Name field) to change the number of days for retention from four days to seven days:
	<pre><auditaction>   <modelstate>     <template></template></modelstate></auditaction></pre>

# **View: Audit Log Details**

To view audit log details for an audit log record, double-click the audit log entry in the audit log grid, right-click the row in the grid and choose **View** from the right-click menu, or highlight the row in the grid and click **View** at the top of the grid. The information on the detail dialog will vary depending on the type of activity that was logged.

The contents of the audit log details dialog will vary depending on the category and object type audited and whether the log item is a new entry or has been updated. The details dialog has four sections.

#### Name

The Keyfactor Command audit **Name** for the selected audit log entry is in the gray title bar at the top of the dialog. This is a useful field to use in the search criteria.

## **Entry Metadata**

Directly below the **Name** at the top left of the dialog is the **Entry Metadata** section, which displays the internal metadata information about the currently displayed detail record:

- Operation
   The type of activity that generated the audit log record (see <u>Audit Log Operations on page 723</u>).
- Time
   The time and date that the audit log entry was generated.
- User
   The user who carried out the activity that generated the audit log.
- Category
   The area of the product in which the auditable activity occurred (see <u>Audit Log Categories on page 731</u>).

Validation Status
 Whether the audit log entry in the database is valid or invalid.

Selecting a different entry in the **Related Entries** section will change the display in this section.

Figure 370: Audit Log Details: Entry Metadata Section

#### **Related Entries**

The **Related Entries** tab displays the history of all the related audit log items (e.g. changes to the same template or certificate) for the selected audit log entry. Click a row in the related entries grid and click **View** to update the details dialog with the details of the audit log item for the selected related entry.

The related entries can be sorted by clicking on a the *Time* or *User* column headers in the results grid. Click the column header again to reverse the sort order.

Figure 371: Audit Log Details: Related Entries Section

**Note:** The Related Entries tab includes all entries, including the initial entry that you opened to reach the tab.

# Selected Entries: Audit Details Pane

The Selected Entry tab of the audit log details dialog will either have one column (for new, or single event, entries) or two (for updated items) showing the details of the auditable action.

The title of a single column pane changes depending on the audit entry event that triggered the entry. It is made up of the category and operation performed to create the entry. The details displayed vary depending on the type object being audited.

Figure 372: Audit Log Details: Single Column Audit Details Pane

The two column pane includes **Before Changes** and **After Changes** sections. Only those details that have a different value as a result of a particular audit event will be displayed. Changed fields with sensitive data will display as \*\*\*\*\*\*.

Figure 373: Audit Log Details: Two Column Audit Details Pane

**Note:** Updates where a field had no value before the update will appear in the single column format.

Figure 374: Audit Log Details Dialog

Click Close to close the details dialog.

## Validate

Highlight a row in the audit log grid and click the **Validate** button to verify whether the selected item is valid or not valid. This function checks the integrity of the audit log data for that grid row to determine whether the data has been tampered with. If the status of the selected item is valid, the validate dialog will indicate this. If the selected item has been tampered with, the validate dialog will indicate that the selected item is not valid.

Figure 375: Audit Log Record is Valid

The validation status of any audit log item can also be viewed in the details dialog, where a status of **Valid:** or **Valid:** will be shown.

Figure 376: Audit Log Details Showing Valid Status

Figure 377: Audit Log Details Showing Invalid Status

## **Audit Log Reference Codes**

The Keyfactor Command audit logs are a record of historical changes that have been made within the product to key systems. The following shows the full list of currently audited areas (areas of the product) and operations (types of activity). The equivalent numeric codes are included for those interested in viewing or analyzing raw log data.

# **Audit Log Operations**

The type of operation performed.

Table 74: Audit Operations

Value	Description
1	Created
2	Updated
3	Deleted
4	Approved
5	Denied
6	Revoked
7	Downloaded
8	Deleted Private Key
9	Renewed
10	Encountered
11	Scheduled Replacement
12	Recovered
13	Imported
14	Removed from Hold
15	Scheduled Add
16	Scheduled Removal
17	Download with Private Key
18	Scheduled
19	Reset
20	Disapproved
21	Restarted
22	Sent

Value	Description
23	Failed
24	Completed
25	Rejected

# **Audit Log Categories**

The area of the product in which the auditable activity occurred. The subcategory name is primarily used in the Keyfactor API or when reviewing downloaded CSV files.

Table 75: Audit Categories

Value	Subcategory Name	Description
2001	Certificate	Certificate
2001	AuditingCertificateScheduledReplacement	Auditing Certificate Scheduled Replacement
2001	AuditingCertificateRequest	Certificate Request
2002	ApiApplication	API Application
2003	Template	Template
2004	CertificateQuery	Certificate Collection/Query
2005	ExpirationAlert	Expiration Alert
2005	ExpirationAlertDefinitionContextModel	Expiration Alert
2006	PendingAlert	Pending Alert
2006	PendingAlertDefinitionContextModel	Pending Alert
2007	ApplicationSetting	Application Setting
2008	IssuedAlert	Issued Alert
2008	IssuedAlertDefinitionContextModel	Issued Alert
2009	DeniedAlert	Denied Alert
2009	DeniedAlertDefinitionContextModel	Denied Alert

		2
Value	Subcategory Name	Description
2010	ADIdentityModel	Security Identity
2011	SecurityRole	Security Role
2012	AuthorizationFailure	Authorization Failure
2013	CertificateSigningRequest	CSR
2014	ServerGroup	SSH Server Group
2015	Server	SSH Server
2016	DiscoveredKey	Rogue Key for Logon
2016	Key	SSH Key
2017	ServiceAccount	SSH Service Account
2018	Logon	SSH Logon
2019	SshUser	SSH User
2020	KeyRotationAlertDefinitionContextModel	SSH Key Rotation Alert
2021	CertificateStore	Certificate Store
2022	JobType	Orchestrator Job Type
2023	AgentSchedule	Orchestrator Job
2024	BulkAgentSchedule	Bulk Orchestrator Job
2025	CertificateStoreContainer	Store Container
2026	Agent	Orchestrator
2027	RevocationMonitoring	Monitoring
2028	License	License
2029	WorkflowDefinition	Workflow Definition
2030	WorkflowInstance	Workflow Instance
2031	WorkflowInstanceSignal	Workflow Instance Signal

Value	Subcategory Name	Description
2032	IdentityProvider	Identity Provider
2033	RoleClaimDefinition	Claim Definition

**Tip:** The Category code of the auditable activity matches the Windows Event ID of the activity.

# **Audit Logging Specifics**

While the Keyfactor Command audit log functionality covers the entire product, the following areas may be of particular interest.

#### **Access Control**

When a user tries to access a page in the Management Portal or an API endpoint that they don't have access to, they will receive an error and a warning will be logged in the audit log.

Insufficient Permissions
The user 'KEYEXAMPLE\eedwards' does not have rights to the requested resource or to perform the requested operation. Please contact the site administrator to obtain permissions.

Figure 378: Management Portal Access Denied Message

The audit log shows the level as *Warning* and the category as *Authorization Failure* with a message detailing the user and the requested page.

# Audit Log 6

View portal actions and logs for auditing. Clicking "Advanced" allows you to build a query based on multiple criteria using AND/OR logic. Select a field and comparison operator in the drop-downs and then enter a comparison value. Click "insert" to add the search criteria to the query field below the selection fields. Each time you click the "insert" button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

Figure 379: Audit Log Authorization Failure Messages

Click View to see the details dialog:

- Username
   The user making the page request.
- Request Route
   The page the user requested.

- Request Type Either API Endpoint or Portal Page.
- HTTP Verb
   This appears for both API requests and portal requests. For API requests, this can help to determine which action was denied.
- User's Roles
   The security role or roles that the user holds (see <u>Security Roles and Claims on page 623</u>). A role will not be listed if the user denied access is not a user in Keyfactor Command.

For more information about the audit log details, see View: Audit Log Details on page 725.

Figure 380: Authorization Failure Audit Log Detail

# **Certificate Operations**

Tracking of operations related to certificates is especially extensive. Certificate-related operations that are audited include:

- · Certificate revocation (Category: Certificate)
- Certificate download (Category: Certificate)
- Enrollment for certificates via PFX enrollment and CSR enrollment (Category: Certificate)
- Certificate renewal via one-click or seeded renewal (Category: Certificate)

- CSR generation, re-download and deletion (Category: CSR)
- Approval of certificate requests made using templates requiring manager approval at the CA level (Category: Certificate Request—see also Workflow on page 739)
- Certificate deletion (Category: Certificate)
- Certificate metadata operations—addition of or updates to metadata tags on certificates (Category: Certificate)
- Certificate collection creation or modification (Category: Certificate)
- Addition of certificates to and removal from certificate stores (Category: Certificate Store)

Figure 381: Audit Logs for Certificates

# Security

The management of security identities and roles to limit access to the Keyfactor Command Management Portal and Keyfactor API generates audit log entries as roles and identities are created, updated, and deleted. This includes the granting of permissions to roles and the assigning of roles to identities (these are considered updates). The Security Identity and Security Role categories do not cover any attempts to access the system. These are tracked separately using the Authorization Failure category (see Access Control on page 733). Successful authorizations are not logged.

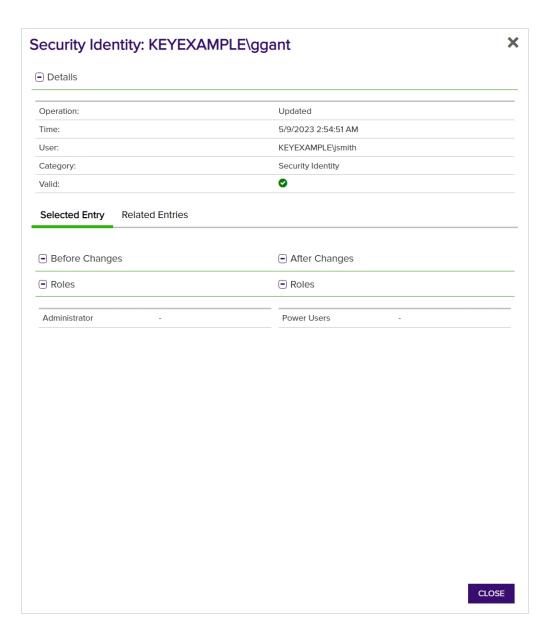

Figure 382: Audit Log Details for Security

## SSH

SSH key management with the Keyfactor Bash Orchestrator generates a wide variety of audit log entries, including:

- An SSH user key is created or updated (with an object name of the user)
- An SSH service account key is created, updated, or deleted (with an object name of the service account)
- An SSH key is updated or deleted (with an object name of the public key fingerprint rather than user or service account name—this references the same key as issued for the user or service

account)

- · An SSH logon is created, updated, or deleted
- · An SSH server is created, updated, or deleted

Comparison

- · An SSH server group is created, updated, or deleted
- A rogue SSH key is identified associated with a logon while scanning a server configured for SSH key management
- · An SSH key rotation alert is created, updated or deleted

#### Audit Log 9

View portal actions and logs for auditing. Clicking "Advanced" allows you to build a query based on multiple criteria using AND/OR logic. Select a field and comparison operator in the drop-downs and then enter a comparison value. Click 'insert' button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

Value

Figure 383: Audit Logs for SSH Management

# System Audit Logs

Audit log entries are created during the initial Keyfactor Command installation process when the initial templates and API applications are configured and application settings established. Audit log entries may also be created when you re-run the Keyfactor Command configuration wizard if you make an auditable change in the wizard. When you upgrade from a previous version of Keyfactor Command or make a change in the configuration wizard to an existing Keyfactor Command installation, the audit log entries will show as *Updated*. The exact number of entries created depends on the configuration options selected, number of templates, and the templates configured for enrollment in Keyfactor Command.

Figure 384: Automated Entries Created by the System in the Audit Log

## Workflow

Audit log entries that are generated for workflow include:

- · Workflow definition is created
- Workflow definition is imported
- · Workflow definition is edited and saved
- · Workflow definition is published
- · Workflow definition is deleted
- Workflow instance is initiated (created)
- Workflow instance is suspended due to workflow configuration (e.g. the workflow requires approval)
- Workflow instance is stopped manually (this appears as an update to the status of the workflow from Can Receive Signals = True to Can Receive Signals = False)
- · Workflow instance is restarted
- · Workflow instance failed
- · Workflow instance completed

#### Audit Log 9

View portal actions and logs for auditing. Clicking "Advanced" allows you to build a query based on multiple criteria using AND/OR logic. Select a field and comparison operator in the drop-downs and then enter a comparison value. Click 'insert' batch the search criteria to the query field below the selection fields. Each time you click the "insert" button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

Figure 385: Audit Log Entries for Workflow

For more information about the audit log and using the audit log search feature, see <u>Audit Log on page 718</u>.

#### **Audit Log Security**

Keyfactor considers the security and integrity of the audit log to be of the utmost importance and takes steps to ensure that transactions are recorded to the audit log accurately and retained

without tampering until they are purged (by default, after 7 years—see <u>Application Settings: Auditing Tab on page 609</u>).

When Keyfactor Command is installed, a 64-byte key is generated for use in securing audit logs. This key is unique for the implementation. The key is encrypted and stored in the secrets table in SQL using either SQL-level encryption or application-level encryption, depending on the level of encryption selected during installation (see *Install the Main Keyfactor Command Components on the Keyfactor Command Server(s): Database Tab* in the *Keyfactor Command Server Installation Guide*). If application-level encryption is selected, use of a hardware security module (HSM) is supported. For more information, see *Acquire a Public Key Certificate for the Keyfactor Command Server* in the *Keyfactor Command Server Installation Guide*.

When an audit log record is created, the key components of it are signed using the unique 64-byte key and stored in the SQL database. The signature is retained and tracked. When the audit log is read, it is validated using the signature. If the signature does not match, the audit log is flagged as invalid (see <u>Validate on page 728</u>), as this could indicate that the record has been tampered with. The following data is included in the key components:

- The date and time at which the action took place.
- The audit message content, which will vary depending on the type of action that was audited. For example, for a modification to a template, this would include:
  - Template common name (short name)
  - Template name
  - Template OID
  - Key size
  - ° Key type
  - Configuration tenant (forest)
  - Private key retention setting
  - Key archival setting
  - Allowed requesters setting

See also Download CSV on page 723.

- The operation type (see Audit Log Operations on page 729).
- The user who performed the auditable action.

In order to access the audit logs, users must be granted the **Read** role permission for the **Auditing** role (see <u>Security Roles and Claims on page 623</u>). Users with auditing Read permissions are allowed to access the audit log page and make API requests to obtain data from the audit log.

**Important:** Be aware that this permission essentially grants a user global read access to the product since the user will be able to view, from the audit log, many of the actions being taken in Keyfactor Command.

Figure 386: Security Role Showing Auditing Permissions Setting

# 2.1.11.6 Event Handler Registration

Event handlers are used with expiration and enrollment (pending, issued and denied certificate requests) alerts to trigger additional automated tasks at the time the alerts are run. Keyfactor Command workflows (see Workflow Definitions on page 230) do not use event handlers.

Keyfactor provides several event handlers out of the box:

# **Expiration Logger**

Log events to the Keyfactor Command server Windows event log (or other machine event log) for each expiration alert when the alert task is triggered.

# **Expiration PowerShell**

Run a PowerShell script on the Keyfactor Command server for each expiration alert when the alert task is triggered.

## **Expiration Renewal**

#### **Issued PowerShell**

Run a PowerShell script on the Keyfactor Command server for each issued certificate alert when the alert task is triggered.

# **Denied Logger**

Log events to the Keyfactor Command server Windows event log (or other machine event log) for each denied request alert when the alert task is triggered.

#### **Denied PowerShell**

Execute a certificate renewal for each expiring certificate that is found in a supported certificate store for each expiration alert when the alert task is triggered.

## **Pending Logger**

Log events to the Keyfactor Command server Windows event log (or other machine event log) for each pending request alert when the alert task is triggered.

# **Pending PowerShell**

Run a PowerShell script on the Keyfactor Command server for each pending request alert when the alert task is triggered.

## **Issued Logger**

Log events to the Keyfactor Command server Windows event log (or other machine event log) for each issued certificate alert when the alert task is triggered.

Run a PowerShell script on the Keyfactor Command server for each denied request alert when the alert task is triggered.

# SSH Key Rotation Logger

Log events to the Keyfactor Command server Windows event log (or other machine event log) for each SSH key rotation alert when the alert task is triggered.

# SSH Key Rotation PowerShell

Run a PowerShell script on the Keyfactor Command server for each SSH key rotation alert when the alert task is triggered.

For information on using built-in event handlers, see <u>Using Event Handlers on page 218</u>.

**Tip**: Click the help icon (2) next to the page title to open the embedded web copy of the *Keyfactor Command Documentation Suite* to this section.

You can also find the help icon at the top of the page next to the **Log Out** button. From here you can choose to open either the *Keyfactor Command Documentation Suite* at the home page or the *Keyfactor API Endpoint Utility*.

## **Custom Event Handler Operations**

Custom event handlers are used by expiration and enrollment alerts (see <u>Alerts on page 166</u>) but **not** by Keyfactor Command workflows (see Workflow on page 229).

## Registering a Custom Event Handler

The built-in event handlers are registered as part of the Keyfactor Command installation. You should only need to use this option if you have a custom event handler.

To register custom event handlers:

- 1. In the Management Portal, browse to System Settings Icon 🌣 > Event Handler Registration.
- 2. On the Event Handler Registration page, click Analyze Handler File.

## Event Handler Registration 9

Use this page to register handlers for various application events, such as Certificate Expiration, Pending Certificate Requests, and Enrollment Authorization.

Figure 387: Event Handler Registration Grid

3. In the Analyze Event Handler Assembly File dialog, enter the file name for the event handler file (provided by Keyfactor if the file has been created by Keyfactor) for analysis and click **Save**.

Figure 388: Event Handler Registration

# **Deleting an Event Handler**

To delete an event handler:

- 1. Browse to System Settings Icon ❖ > Event Handler Registration.
- 2. Highlight the row in the grid and click **Delete** at the top of the grid.

## Editing an Event Handler

To edit an event handler:

- 1. Browse to System Settings Icon ❖ > Event Handler Registration.
- 2. Double-click the event handler or highlight the row in the grid and click **Edit** at the top of the grid.
- 3. In the Event Handler Registration dialog, you can change the **Display Name** for the event handler, if desired. This name appears in the dropdowns in the expiration, pending request, issued certificate, and denied request alert configuration dialogs. You can also disable the event handler by unchecking the **Enabled** box. If you disable an event handler, it will not appear in the dropdowns in the alert configuration dialogs.
- 4. Click Save.

Figure 389: Event Handler Registration Editor

### 2.1.11.7 Privileged Access Management (PAM)

Privileged access management (PAM) functionality in Keyfactor Command allows for configuration of third party PAM providers to secure certificate stores, credentials for accessing certificate authorities, and similar. PAM functionality is provided using custom PAM extensions. Keyfactor provides several PAM extensions on the publicly-facing Keyfactor GitHub:

https://keyfactor.github.io/integrations-catalog/content/pam

The Keyfactor Command PAM solution is made up of three elements:

- Install an appropriate custom PAM provider extension (see <u>Installing Custom PAM Provider</u> Extensions on the next page).
- Create a PAM provider record in Keyfactor Command (see <u>PAM Provider Configuration in Keyfactor Command on page 751</u>).
- Apply PAM provider security to individual certificate stores (see <u>Adding or Modifying a Certificate Store on page 414</u>), certificate authority records and other locations as needed in Keyfactor Command.

PAM Extensions support installation either locally (on the Keyfactor Command server) or remotely (on each instance of the Keyfactor Universal Orchestrator that will be accessing PAM secrets). You will need to make a determination as to which installation type best meets your needs:

- Local (on the Keyfactor Command server) installations support any type of PAM secret storage supported by Keyfactor Command, including certificate stores and certificate authority secrets, but may require greater accessibility between the Keyfactor Command server and the PAM provider than is desired for your environment.
- Remote (on the orchestrator) installations support PAM secret storage only for the certificate stores managed by the Universal Orchestrator where the PAM extension is installed, but may be a better choice in terms of network accessibility for your environment.

**Tip:** Click the help icon (②) next to the page title to open the embedded web copy of the *Keyfactor Command Documentation Suite* to this section.

You can also find the help icon at the top of the page next to the **Log Out** button. From here you can choose to open either the *Keyfactor Command Documentation Suite* at the home page or the *Keyfactor API Endpoint Utility*.

### **Installing Custom PAM Provider Extensions**

Before you can begin to use a third party PAM provider with Keyfactor Command, you need to acquire and install the appropriate custom-built PAM extension for your desired PAM provider from the Keyfactor GitHub:

https://keyfactor.github.io/integrations-catalog/content/pam

To find a package on GitHub:

1. Visit the link above to find your desired package, and click either **Github Repository** or **View source on GitHub** to go to the package page on GitHub.

### CyberArk PAM Provider

A Keyfactor PAM Provider plugin supporting credential retrieval with a CyberArk Credential Provider. The Central Credential Provider (cloud-losted) can be used, or the standard Credential Provider with installed SDK.

Github Repository

Figure 390: View Packages as Part of a List

# CyberArk PAM Provider

### **PAM Provider**

A Keyfactor PAM Provider plugin supporting credential retrieval with a CyberArk Credential Provider. The Central Credential Provider (cloud-hosted) in be used, or the standard Credential Provider with installed SDK.

Figure 391: View Packages on Individual Pages

2. On the GitHub page, on the right-hand side, click the link for the Latest version.

Figure 392: Find the Latest Version of the Package

3. On the GitHub version page in the Assets section, click the package name to download the zip file

Figure 393: Download the Package Zip File

4. On the main extension GitHub page, review the documentation for the specific extension. Here you will find supported platforms, prerequisites, and extension-specific installation and configuration instructions. The below instructions only cover where to place the extension files on either the Keyfactor Command or the orchestrator and building custom manifest.json files (changes to which aren't needed for extensions from GitHub unless you are customizing something), but not the details for creation of a PAM provider type in Keyfactor Command for the extension or any other customization specific to a given extension.

Extensions support installation either locally (on the Keyfactor Command server) or remotely (on each instance of the Keyfactor Universal Orchestrator that will be accessing PAM secrets). Be sure to follow the installation instructions for the type of installation you wish to do:

- Local (on the Keyfactor Command server) installations support any type of PAM secret storage supported by Keyfactor Command, including certificate stores and certificate authority secrets, but may require greater accessibility between the Keyfactor Command server and the PAM provider than is desired for your environment.
- Remote (on the orchestrator) installations support PAM secret storage only for the certificate stores managed by the Universal Orchestrator where the PAM extension is installed, but may be a better choice in terms of network accessibility for your environment.

### Installation on the Keyfactor Command Server

To install a PAM extension on the Keyfactor Command server:

 Using the Keyfactor API, add a PAM provider type in Keyfactor Command for the custom PAM extension. See the Adding a PAM Provider Type instructions for your selected PAM extension. The following is an example request body for a POST /PamProviders/Types request to create a PAM provider type for the Delinea extension:

```
"Name": "Delinea-SecretServer",
   "Parameters":[
      {
         "Name": "Host",
         "DisplayName": "Secret Server URL",
         "InstanceLevel":false,
         "DataType": "string"
      },
         "Name": "Username",
         "DisplayName": "Secret Server Username",
         "InstanceLevel":false,
         "DataType": "secret"
      },
      {
         "Name": "Password",
         "DisplayName": "Secret Server Password",
         "InstanceLevel":false,
         "DataType": "secret"
      },
         "Name": "SecretId",
         "DisplayName": "Secret Server Secret ID",
         "InstanceLevel":true,
         "DataType": "string"
      },
         "Name": "SecretFieldName",
         "DisplayName": "Secret Field Name",
         "InstanceLevel":true,
         "DataType": "string"
     }
   ]
}
```

2. On the Keyfactor Command server, locate the \WebAgentServices\Extensions\PamProviders directory within the install directory. By default, this is:

C:\Program Files\Keyfactor\Keyfactor Platform\WebA-gentServices\Extensions\PamProviders

3. Under the Pam Providers directory, create a new directory with an appropriate name for the PAM extension (e.g. CyberArk). This name is for reference only and does not need to match any names used elsewhere.

- 4. Place the files you downloaded for the PAM extension in the new directory.
- 5. In the directory for the PAM extension, locate the file called manifest.json. The manifest.json file should be placed in the same directory as the DLL(s) for the extension.
- 6. Using a text editor, open the manifest.json file for editing and configure it appropriately for the extension, if needed. See the *Configuring the Server Side manifest.json File* instructions for your selected PAM extension for exact details. The following Delinea manifest.json file is provided as an example. Things to note:
  - · Areas highlighted in red and yellow, below, will vary between manifest.json files.
  - When you add your PAM provider into Keyfactor Command, the name you give it must match the name highlighted in red, below (for your manifest.json file).
  - In most cases, server-side files should not need customization.

- 7. If you'll be using PAM to store secrets for uses other than certificate stores, repeat the above steps for the PamProviders directories found here, by default:
  - C:\Program Files\Keyfactor\Keyfactor Platform\WebConsole\Extensions\PamProviders
  - C:\Program Files\Keyfactor\Keyfactor Platform\KeyfactorAPI\Extensions\PamProviders

**Note**: Step 1 (add a PAM provider type into Keyfactor Command) does not need to be repeated. The same PAM provider type and PAM provider may be used from multiple areas of the product.

8. Restart the web server services (iisreset) on the Keyfactor Command to complete the implementation.

### Installation on the Keyfactor Universal Orchestrator Server

To install a PAM extension on a Universal Orchestrator for use by that orchestrator only:

 Using the Keyfactor API, add a PAM provider type in Keyfactor Command for the custom PAM extension. See the Adding a PAM Provider Type instructions for your selected PAM extension. The following is an example request body for a POST /PamProviders/Types request to create a PAM provider type for the Delinea extension:

```
{
   "Name": "Delinea-SecretServer",
   "Parameters":[
      {
         "Name": "Host",
         "DisplayName": "Secret Server URL",
         "InstanceLevel":false,
         "DataType": "string"
      },
         "Name": "Username",
         "DisplayName": "Secret Server Username",
         "InstanceLevel":false,
         "DataType": "secret"
      },
         "Name": "Password",
         "DisplayName": "Secret Server Password",
         "InstanceLevel":false,
         "DataType": "secret"
      },
         "Name": "SecretId",
         "DisplayName": "Secret Server Secret ID",
         "InstanceLevel":true,
         "DataType": "string"
      },
         "Name": "SecretFieldName",
         "DisplayName": "Secret Field Name",
         "InstanceLevel":true,
         "DataType": "string"
      }
   ]
}
```

2. On the Universal Orchestrator server, locate the extensions directory within the install directory. By default, this is:

C:\Program Files\Keyfactor\Keyfactor Orchestrator\extensions

- 3. Under the extensions directory, create a new directory with an appropriate name for the PAM extension (e.g. CyberArk). This name is for reference only and does not need to match any names used elsewhere.
- 4. Place the files you downloaded for the PAM extension in the new directory.
- 5. In the directory for the PAM extension, locate the file called manifest.json. The manifest.json file should be placed in the same directory as the DLL(s) for the extension.
- 6. Using a text editor, edit the manifest.json file and configure it appropriately for the extension. See the Configuring the Client Side manifest.json File instructions for your selected PAM extension for exact details. The following Delinea manifest.json file is provided as an example. Things to note:
  - Areas highlighted in red and yellow, below, will vary between manifest.json files.
  - Areas shown in red text are examples of items that need to be customized for your environment.
  - When you add your PAM provider into Keyfactor Command, the name you give it must match the name highlighted in red, below (for your manifest.json file).

7. Restart the Universal Orchestrator service (see *Start the Universal Orchestrator Service* in the *Keyfactor Orchestrators Installation and Configuration Guide*).

### PAM Provider Configuration in Keyfactor Command

Any third-party privilege access management (PAM) providers you wish to configure for use with Keyfactor Command must be defined first on the PAM Providers page before they can be assigned to certificate stores (see Certificate Stores on page 409), used for explicit credentials on a CA (see Adding or Modifying a CA Record on page 355), or used to provide authentication in workflow steps

(see ). Keyfactor Command supports multiple custom-built PAM providers are available on the Keyfactor GitHub:

### https://keyfactor.github.io/integrations-catalog/content/pam

PAM providers can either be local (server side) or remote (client side). When configured locally, the configuration information to connect to the PAM provider exists on the Keyfactor Command server and the PAM provider must be routable from the Keyfactor Command server (for example, on the same network) to retrieve secret information. When configured remotely, the configuration information to connect to the PAM provider exists on the Keyfactor Universal Orchestrator managing the certificate stores using the PAM provider and the PAM provider must be routable from the Universal Orchestrator.

**Tip**: The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

PAM > Modify
PAM > Read
Certificate Stores > Modify

Permissions for certificate stores can be set at either the global or certificate store container level. See *Container Permissions* in the *Keyfactor Command Reference Guide* for more information about global vs container permissions.

## Adding or Modifying a PAM Provider

The PAM provider configuration can be edited at any time, even if it is used on existing records.

To define a new PAM provider or modify an existing one:

- 1. In the Management Portal, browse to System Settings Icon \*> Privileged Access Management.
- 2. On the PAM Providers page, click **Add** to create a new provider, or, to modify an existing provider, double-click the provider, right-click the provider and choose **Edit** from the right-click menu, or highlight the row in the providers grid and click **Edit** at the top of the grid.
- 3. In the PAM Providers dialog, check the **Remote Provider** box if you are adding a PAM provider for a PAM extension installed on a Universal Orchestrator.

A remote PAM provider generally exists outside the local network of the Keyfactor Command server. This option allows you to specify the secret information in Keyfactor Command in the same way as you would with a local PAM provider without needing to enter PAM provider configurations in Keyfactor Command (other than a base remote provider link). The PAM provider configuration information is, instead, supplied in the orchestrator's PAM manifest (see <a href="Installing Custom PAM Provider Extensions on page 745">Installing Custom PAM Provider Extensions on page 745</a>). Remote PAM providers are only supported for use with certificate stores and the Keyfactor Universal Orchestrator version 10.0 or greater.

Figure 394: Remote PAM Provider

4. Select a **Provider Type** in the dropdown. This is the name of the software vendor that provides your Privilege Access Management solution. This field cannot be modified on an edit.

**Note**: If a provider type does not already exist for the PAM provider you are adding, you will need to create a new supported type before completing this step (see <u>Installing</u> Custom PAM Provider Extensions on page 745).

5. In the **Name** field, enter the name for the PAM provider. This name is used to identify the PAM provider throughout Keyfactor Command.

**Important:** The name you give to your PAM provider in Keyfactor Command must match the name of the PAM provider as referenced in the manifest.json file (see <u>Installing</u> Custom PAM Provider Extensions on page 745).

6. The remainder of the fields in the dialog will vary depending on the provider type selected. If you checked Remote Provider, no further configuration is needed in this dialog. For example:

CyberArk Extension (Central Credential Provider)

- Application ID: The name/ID of the application created for Keyfactor Command.
- CyberArk Host and Port: The hostname or IP address where CyberArk is hosted, including port. Do not include http/https.
- CyberArk API Site: The web server site name to which CyberArk has been deployed. By default, this is AIMWebService.

Figure 395: Create CyberArk Provider

#### **Delinea Extension**

- **Secret Server URL**: The URL to the Secret Server vault instance, including port number if applicable (e.g. https://websrvr38.keyexample.com/SecretServer).
- **Secret Server Username**: The username of the user that will be used to connect to SecretServer.
- Secret Server Password: The password of the user that will be used to connect to Secret Server.

Figure 396: Create Delinea PAM Provider

### HashiCorp Extension

- **Vault Host**: The URL to the vault instance, including port number if applicable (e.g. https://websrvr35.keyexample.com:8200).
- Vault Token: The access token for the vault (assuming Kerberos authentication is not used).
- KV Engine Path: The path to the vault secrets. The default is v1/secret/data.

Figure 397: Create HashiCorp PAM Provider

7. Click Save to save the provider.

### **Deleting a PAM Provider**

To delete a provider, highlight the row in the providers grid and click **Delete** at the top of the grid or right-click the provider in the grid and choose **Delete** from the right-click menu.

**Tip:** If a PAM provider has been associated with any certificate stores or CAs, it cannot be deleted.

### 2.1.11.8 Identity Providers

Identity providers in Keyfactor Command are used to provide a method for authenticating access to the Keyfactor Command Management Portal and Keyfactor API. An identity provider for Keyfactor Command is selected during the installation process and typically would not need to be updated. However, if you decide to migrate your Keyfactor Command implementation from one identity provider to another, you can add the new provider to which you will migrate using the options in this interface. Authentication with only one identity provider at a time for a given Keyfactor Command server is supported.

**Tip**: Click the help icon (2) next to the page title to open the embedded web copy of the *Keyfactor Command Documentation Suite* to this section.

You can also find the help icon at the top of the page next to the **Log Out** button. From here you can choose to open either the *Keyfactor Command Documentation Suite* at the home page or the *Keyfactor API Endpoint Utility*.

### **Identity Provider Operations**

On the identity providers page, you can modify existing identity providers, but you cannot add new identity providers. New identity providers should be added by re-running the Keyfactor Command Configuration Wizard and adding a new identity provider on the Authentication tab (see *Install the Main Keyfactor Command Components on the Keyfactor Command Server(s): Authentication Tab* in the *Keyfactor Command Server Installation Guide*). Identity providers cannot be deleted.

To modify an identity provider:

- 1. In the Management Portal, browse to System Settings Icon \*> Identity Providers.
- 2. On the Identity Providers page, highlight a row and click **Edit** from the top of the grid or from the right click menu to modify an existing provider.
- 3. On the Editing Identity Provider page, fill in each tab of the dialog with the information desired for the selected identity provider.
  - a. On the Details tab, enter a short *Name* and *Display Name* for the provider. The *Typeld* cannot be edited.

**Important:** The value in the Name field must match the provider name referenced in the redirect URLs (see <u>Configuring Keyfactor Identity Provider and Collecting Data for the Keyfactor Command Installation</u>).

# Identity Providers 9

Editing Identity Provider: Command-OIDC

Figure 398: Details for an Identity Provider

b. On the Parameters tab, select each parameter to configure and click **Edit** to open the Edit <Parameter Name> Parameter dialog, the contents of which will vary depending on the parameter selected. For information about the specific parameters, see <a href="Table 76">Table 76</a>: Identity Provider Parameters.

Figure 399: Edit Parameters for an Identity Provider

### 4. Click **Save** to save the role.

Table 76: Identity Provider Parameters

Name	Туре	Example	Description
Admin Querying Client Id	1- String	Command-Token-Query	The client ID of the service account that Keyfactor Command uses to query the identity provider database for information when resolving substitutable special text tokens.  For Keyfactor Identity Provider, this is created as a client (see <i>Using Keyfactor Identity Provider: Service Accounts</i> in the <i>Keyfactor Command Server Installation Guide</i> ).  This parameter is required.
Admin Querying Client Secret	1- String		The client secret of the service account that Keyfactor Command uses to query the identity provider database for information when resolving substitutable special text tokens.

Name	Туре	Example	Description
			For Keyfactor Identity Provider, this is created as a client (see <i>Using Keyfactor Identity Provider: Service Accounts</i> in the <i>Keyfactor Command Server Installation Guide</i> ).  This parameter is required.
Audience	1- String	Command-OIDC-Client	The audience value for the identity provider. This should be set to the same value as the <i>Client Id</i> . For Keyfactor Identity Provider, this should be:  Command-OIDC-Client
			This parameter is required.
Authority  1 - https://my-keyidp-serv-er.keyexample.com/realr factor	er.keyexample.com/realms/Key-	The issuer/authority endpoint URL for the identity provider.  For Keyfactor Identity Provider, this is included among the information that can be found on the OpenID Endpoint Configuration page, a link to which can be found on the Realm Settings page (see Gathering Keyfactor Identity Provider Data for the Keyfactor Command Installation in the Keyfactor Command Server Installation Guide). It is automatically returned by the Discovery Document Endpoint  Fetch step. Review it to confirm that it appears correct.  This parameter is required.	
			Tip: When you add or update an identity provider, the provider's discovery document is validated based on this authority URL. The discovery document is also validated periodically in the background. The following are validated:  • That the discovery document is reachable using the Authority value provided and

Name	Туре	Example	Description
			can be parsed into a valid discovery document.  That the Authority URL matches the Issuer returned in the discovery document.  That all the URLs on the discovery document are using HTTPS.  That the JSONWebKeySetUri value is included on the discovery document.  That any endpoint configuration values (Authorization Endpoint, Token Endpoint, UserInfo Endpoint, JSONWebKeySetUri) that have been saved or are being saved match—including case—the values returned in the discovery document. The UserInfo Endpoint is not a required configuration field, but if a value is provided, it must match what's in the discovery document.  If any of these validation tests fail, any identity provider changes in process will not be saved and an error will be displayed or logged.
Authorization Endpoint	1- String	https://my-keyidp-serv- er.keyexample.com/realms/Key- factor/protocol/openid- connect/auth	The authorization endpoint URL for the identity provider.  For Keyfactor Identity Provider, this is included among the information that can be found on the OpenID Endpoint Configuration page, a link to which can be found on the Realm Settings page (see Gathering Keyfactor Identity Provider Data for the Keyfactor Command Installation in the Keyfactor Command Server Install-

Name	Туре	Example	Description
			ation Guide). It is automatically returned by the Discovery Document Endpoint  Fetch step. Review it to confirm that it appears correct.  This parameter is required.
Client Id	1- String	Command-OIDC-Client	The ID of the client application created in the identity provider for primary application use. For Keyfactor Identity Provider, this should be:  Command-OIDC-Client  For more information, see Gathering Keyfactor Identity Provider Data for the Keyfactor Command Installation in the Keyfactor Command Server Installation Guide).  This parameter is required.
Client Secret	2 - Secret		The secret for the client application created in the identity provider for primary application use.  For Keyfactor Identity Provider, see Gathering Keyfactor Identity Provider Data for the Keyfactor Command Installation in the Keyfactor Command Server Installation Guide for help locating this. It is automatically returned by the Discovery Document Endpoint Fetch step. Review it to confirm that it appears correct.  Supported methods to store secret information are:  Store the secret information in the Keyfactor secrets table.  A Keyfactor secret is a user-defined username or password that is encrypted and stored securely in the Keyfactor Command database.  Load the secret information from a PAM provider.  See Privileged Access Management (PAM) in the Keyfactor Command

Name	Туре	Example	Description
			Reference Guide for more information.
			This parameter is required.
Discovery Document Endpoint	1- String	https://my-keyidp-serv- er.keyexample.com/realms/Key- factor/.well-known/openid- configuration	The discovery URL for the identity provider.  For Keyfactor Identity Provider, this is the link to the OpenID Endpoint Configuration page, which can be found on the Realm Settings page (see Gathering Keyfactor Identity Provider Data for the Keyfactor Command Installation in the Keyfactor Command Server Installation Guide). Populate this value and click Fetch to populate the remainder of the fields in this section, if desired.  If you opt not to populate this field or if the discovery document does not return a valid response, the remainder of the fields in this section of the configuration will need to be configured manually. This value is not stored in the database.
Fallback Unique Claim Type	1- String	cid	A backup value used to reference the type of claim used for users in the identity provider in case the primary referenced name does not contain a value.  This parameter is required.
JSON Web Key Set Uri	1- String	https://my-keyidp-serv- er.keyexample.com/realms/Key- factor/protocol/openid- connect/certs	The JWKS (JSON Web Key Set) URL for the identity provider.  For Keyfactor Identity Provider, this is included among the information that can be found on the OpenID Endpoint Configuration page, a link to which can be found on the Realm Settings page (see Gathering Keyfactor Identity Provider Data for the Keyfactor Command Installation in the Keyfactor Command Server Installation Guide). It is automatically returned by the Discovery Document Endpoint  Fetch step. Review it to confirm that it appears correct.

Name	Туре	Example	Description	
			This parameter is required.	
Name Claim Type	1- String	preferred_username	The name used to reference the type of user claim for the identity provider. For Keyfactor Identity Provider, this should be:  preferred_username  This parameter is required.	
Role Claim Type	1- String	groups	The value used to reference the type of group claim for the identity provider. For Keyfactor Identity Provider, this should be:  groups  This parameter is required.	
Timeout	1 - String	60	The number of seconds a request to the identity provider is allowed to process before timing out with an error.	
Token Endpoint	1- String	https://my-keyidp-serv- er.keyexample.com/realms/Key- factor/protocol/openid- connect/token	The token endpoint URL for the identity provider.  For Keyfactor Identity Provider, this is included among the information that can be found on the OpenID Endpoint Configuration page, a link to which can be found on the Realm Settings page (see Gathering Keyfactor Identity Provider Data for the Keyfactor Command Installation in the Keyfactor Command Server Installation Guide). It is automatically returned by the Discovery Document Endpoint  Fetch step. Review it to confirm that it appears correct.  This parameter is required.	
Unique Claim Type	1- String	sub	The value used to reference the type of claim used for users in the identity provider. For Keyfactor Identity Provider, this should be (for subject):	

Name	Туре	Example	Description
			sub
			This parameter is required.
User Info Endpoint	1- String	https://my-keyidp-serv- er.keyexample.com/realms/Key- factor/protocol/openid- connect/certs	The user info endpoint URL for the identity provider.  For Keyfactor Identity Provider, this is included among the information that can be found on the OpenID Endpoint Configuration page, a link to which can be found on the Realm Settings page (see Gathering Keyfactor Identity Provider Data for the Keyfactor Command Installation in the Keyfactor Command Server Installation Guide). It is automatically returned by the Discovery Document Endpoint  Fetch step. Review it to confirm that it appears correct.
User Query Endpoint	1- String	https://my-keyidp-serv- er.keyexample.com /admin/realms/Keyfactor	The user query endpoint URL for the identity provider.  For Keyfactor Identity Provider, this is the base URL for the Keyfactor Identity Provider REST API and has an expected value of:  https:// <host>/admin/reals/<realm_name>  This parameter is required.</realm_name></host>

# **Using the Identity Provider Search Feature**

The search function allows you to query the database for information. The same query structure is used in multiple locations within the Keyfactor Command Management Portal.

When you first open the page, you will see the simple search option. To execute a search, select the field and comparison operators in the dropdowns and type something on which to search in the value field (if applicable). If you select an *is null* or *is not null* comparison operator, the value field will be grayed out. Click the **Search** button to execute the query.

Each query consists of three parts:

# **Query Field**

The available fields for querying vary depending on the area of the Management Portal in which the search is used. On this page, the queries can be done on the following built-in fields:

DisplayName	Private
Complete or partial matches with the display name of the identity provider.  Name	Whether the identity provider is marked as private, true/false.  ProviderType
Complete or partial matches with the name of the identity provider.	Complete or partial matches with the provider type for the identity provider. Supported provider types are:  • Active Directory • Azure
	Generic

# **Comparison Operator**

The query comparison operators vary depending on the type of field selected and the specific properties of the field. The list below shows the dropdown list comparison operators, as well as the equivalent query language syntax (in parentheses).

Most string fields (the vast majority of the built-in fields) support:

<ul><li>Is equal to (-eq)</li></ul>	<ul> <li>Starts with (-startswith)</li> </ul>
<ul> <li>Is not equal to (-ne)</li> </ul>	<ul> <li>Ends with (-endswith)</li> </ul>
<ul> <li>Contains (-contains)</li> </ul>	<ul> <li>Is null (-eq NULL)</li> </ul>
<ul> <li>Does not contain (-notcontains)</li> </ul>	<ul> <li>Is not null (-ne NULL)</li> </ul>
Most date and integer fields support:	
<ul><li>Is equal to (-eq)</li></ul>	<ul> <li>Is greater than (-gt)</li> </ul>
<ul> <li>Is not equal to (-ne)</li> </ul>	<ul> <li>Is greater than or equal to (-ge)</li> </ul>
<ul> <li>Is less than (-lt)</li> </ul>	<ul> <li>Is null (-eq NULL)</li> </ul>
<ul> <li>Is less than or equal to (-le)</li> </ul>	<ul> <li>Is not null (-ne NULL)</li> </ul>
Most Boolean (true/false) fields support:	
• Is equal to (-eq)	<ul><li>Is null (-eq NULL)</li></ul>
• Is not equal to (-ne)	• Is not null (-ne NULL)

### **Comparison Value**

The value you enter for comparison must match the field type. For example, integer fields only support numerical values. String fields support all alphanumeric characters. Boolean fields only support True or False. The value field is not case sensitive. Date fields support only properly formatted dates and will initially display as mm/dd/yyyy. You can choose to populate the date field by:

- Clicking in a date Value field to open a pop-up calendar to select a date that will populate the field.
- Clicking in a segment of the date format (i.e., mm/dd/yyyy) and entering a value. As you continue to type in any one segment, the cursor will keep moving onto the next segment.

The results that match your search criteria will be displayed in the results grid below the search selection options.

#### **Advanced Searches**

On any search page you can click **Advanced** to the right of the Search button to display the advanced search options. Click **Simple** to close the advanced search options again.

### **Multiple Criteria**

Using the advanced search options, you can build a query based on multiple criteria using AND/OR logic. As with a simple search, you select a field and comparison operator in the drop-downs and then enter a comparison value, if applicable. Click **Insert** to add the search criteria to the query field below the selection fields. Use the selection fields to build multiple search criteria. Each time you click the insert button, an AND is added between the previous search criteria and the newly added one. You can change the AND to an OR if desired. You can use parentheses around portions of the query along with AND/OR to change the query meaning.

For example, for certificate searches:

```
(CN -contains "appsrvr" AND IssuedDate -ge "01/01/2022") OR (CN -contains "appsrvr" AND TemplateShortName -contains "web")
```

This query will return all the certificates issued on or after January 1, 2022 with the string appsrvr in the CN and also all certificates issued at any time with the string appsrvr in the CN using a template referencing web. When you have entered all the desired search criteria, click **Search** to execute the query. If you wish to clear the query field and start over, click the **Clear** button.

### 2.1.11.9 SMTP Configuration

SMTP settings to enable Keyfactor Command to deliver reports and alerts via email are generally specified during initial Keyfactor Command installation and configuration, but can be modify through the Management Portal if needed.

**Tip:** The following permissions (see *Security Roles and Claims* in the *Keyfactor Command Reference Guide*) are required to use this feature:

To make a change to these settings:

- 1. In the Management Portal, browse to System Settings Icon \*> SMTP Configuration.
- 2. On the SMTP Configuration page, modify the configuration as needed.

Figure 400: SMTP Configuration

- 3. Enter the FQDN of your SMTP server in the Host field.
- 4. Enter the SMTP port (default is 25) in the **Port** field.
- 5. Check the **Use SSL** box if this option is supported by your mail server. Your mail server may not be configured to support TLS/SSL.
- 6. Set the **Sender Account** name in the form of an email address (e.g. user@keyexample.com). Depending on the email configuration in your environment, the sender account may need to be a valid user on your mail server or you may be able to put anything in this field.
- 7. Set the **Sender Name** as desired. This is the name that appears as the "from" in the user's mail client both with anonymous authentication and explicit credentials.
- 8. Select the appropriate authentication method for your environment. Some mail servers will accept anonymous. Others may not. If your mail server requires that you provide a username and password for a specific valid user, select the Explicit Credentials radio button and click Configure Credentials. Enter the valid user's Active Directory username and password in DOMAIN\username format in the Configure SMTP Relay Authorization Settings dialog. For most

- mail server configurations, the user you select here must have as a valid email address the email address you set in the *Sender Account* field.
- 9. You may test the settings prior to saving them. To test the SMTP settings, click the **Test** button, enter a valid email address for a mailbox you can open in the **Send a Test SMTP Message** dialog and click **Send**. Verify that the test email is delivered.

Figure 401: Send an SMTP Test Message

10. Click **Save** to save any changes you have made.

To cancel any changes you've made without saving, click the **Undo** button.

### 2.1.11.10 Component Installations

On the Component Installations page you can view the components installed on each of your Keyfactor Command servers and, optionally, delete a server if it has been removed from service. The server Hostname and Database name of the Keyfactor Command instance are found on this page.

To delete a server, highlight the row in the component grid and click **Delete** at the top of the grid or right-click the row in the grid and choose **Delete** from the right-click menu. Servers should not be deleted if they are serving any active role in the Keyfactor Command environment, as this operation cannot be undone.

### Component Installations 9

Component Installations lists the servers that various Keyfactor components have been installed on. Use this page to decommission a Keyfactor server that is no longer in use.

Figure 402: Component Installations

**Tip:** Click the help icon (②) next to the page title to open the embedded web copy of the *Keyfactor Command Documentation Suite* to this section.

You can also find the help icon at the top of the page next to the **Log Out** button. From here you can choose to open either the *Keyfactor Command Documentation Suite* at the home page or the *Keyfactor API Endpoint Utility*.

### 2.1.11.11 Licensing

In the Licensing section of the Management Portal you can view the details of your existing license and replace it with a new license, if desired.

To view your existing license, browse to *System Settings Icon* > *Licensing*. The license shows you the features that are enabled for your Keyfactor Command implementation.

For information on monitoring for license expiration, see <u>License Expiration Monitoring and Rotation on page 817</u>.

# Licensing

Figure 403: Keyfactor Command License

If you purchase a new license from Keyfactor that enables additional features or extends the expiration date, you can upload it on the Licensing page. To do this:

- 1. In the Management Portal, browse to System Settings Icon \*> Licensing.
- 2. On the Licensing page, click Replace. The Confirm Operation dialog box will open.
- 3. Click **OK** to open the dialog to upload a new license.

Figure 404: Upload a New Keyfactor Command License

- 4. Click the **Browse** button and browse to the location on the file system where the new license file provided by Keyfactor is stored.
- 5. The new license will appear next to the existing license. Compare them to confirm that you wish to install the new license and then click the **Save** to button to complete the license change.

### Licensing

Determines if the installation is validly licensed, and also the number of licenses where applicable.

Figure 405: Save a New Keyfactor Command License

6. On the Keyfactor Command server, restart the IIS services (iisreset) and refresh the browser.

**Important:** If you are installing a new license because your existing license is expiring and you use the Keyfactor CA Policy Module, be aware that the license needs to be installed separately for the policy module (see <u>License Expiration Monitoring and Rotation on page 817).</u>

**Tip:** Click the help icon (2) next to the page title to open the embedded web copy of the *Keyfactor Command Documentation Suite* to this section.

You can also find the help icon at the top of the page next to the **Log Out** button. From here you can choose to open either the *Keyfactor Command Documentation Suite* at the home page or the *Keyfactor API Endpoint Utility*.

# 2.2 Operations

Once your Keyfactor Command implementation is up and running, there are a few things you should do regularly to make sure that it stays that way, including backing up to prepare for disaster recovery and monitoring logs and alerts to identify potential issues early and have an overall sense of the health of your Keyfactor Command environment. This section includes information on these things along with some reference information and guidance for optional configuration.

# 2.2.1 Extending and Customizing Keyfactor Command

There are several options for adding to your Keyfactor Command implementation with custom extensions, handlers, and scripts. There are also a few options for customizations. This section provides an overview of some of the available options.

- PowerShell scripts can be executed from workflows and using event handlers in alerts. For more information, see PowerShell Scripts on page 219.
- The Keyfactor Universal Orchestrator supports the use of custom-built extensions to extend functionality to a variety of certificate store types and devices for management (see *Installing Custom-Built Extensions* in the *Keyfactor Orchestrators Installation and Configuration Guide*).
- The Keyfactor Universal Orchestrator supports the option to implement custom-built certificate store jobs using one or more scripts (PowerShell or Bash) rather than a full extension (see Configuring Script-Based Certificate Store Jobs in the Keyfactor Orchestrators Installation and Configuration Guide).
- Custom event handlers can be built for use with alerts (see <u>Custom Event Handler Operations on page 742</u>).
- The Keyfactor AnyCA Gateway REST and AnyCA Gateway (previous version) support the use of
  publicly available extensions to allow for functions such as certificate enrollment and management from Keyfactor Command to a variety of third-party CA vendors (e.g. DigiCert, Entrust,
  GoDaddy). For more information, see the separate gateway documentation and the Keyfactor
  GitHub:

Keyfactor AnyGateway (Older Version)

Keyfactor AnyCA Gateway REST

https://keyfactor.github.io/integrations-catalog/content/ca-gateway

- The Keyfactor Command logo on the banner at the top of the Management Portal can be replaced with an alternate image of your choosing (see <u>Customize the Management Portal Banner Logo on the next page</u>).
- Customizations can be done to orchestrator API configuration settings, SQL connection settings, Keyfactor Command Service job settings and more using appsetting.json files (see Keyfactor Command Appsetting.json Files on the next page).
- The executable used to run the Keyfactor Command Service can be changed from an exe to a signed dll for environments where this is an important requirement (see <a href="Keyfactor Command Service Executable on page 788">Keyfactor Command Service Executable on page 788</a>).
- Microsoft CA key recovery can be configured on the Keyfactor Command to allow private keys archived in a Microsoft CA to be retrieved in Keyfactor Command (see <u>Configuring Key</u> Recovery for Keyfactor Command on page 789).
- Client certificates used for orchestrator authentication can be renewed using a client certificate renewal extension (see Register a Client Certificate Renewal Extension in the Keyfactor Orchestrators Installation and Configuration Guide).
- Orchestrators can be auto-registered to Keyfactor Command using a custom auto-registration handler (see <u>Custom Auto-Registration Handlers on page 496</u>).
- At the conclusion of orchestrator jobs a custom handler can be run (see Editing Job Completion Handlers).

 Privileged Access Management (PAM) providers can be configured either on the Keyfactor Command server or the Keyfactor Universal Orchestrator (see <u>Installing Custom PAM Provider</u> Extensions on page 745).

### 2.2.1.1 Customize the Management Portal Banner Logo

You can replace the Keyfactor logo at the top left of the Management Portal with your logo, or any .png image, to customize the appearance for your users. The new image will be displayed across the product for every user accessing the Management Portal. This cannot be selectively applied.

To replace the Keyfactor logo:

1. In Windows Explorer, navigate to the \WebConsole\wwwroot\images directory under the directory in which Keyfactor Command is installed. By default, this is:

C:\Program Files\Keyfactor\Keyfactor Platform\WebConsole\wwwroot\images

- 2. Rename the Keyfactor *Banner.png* file to *Banner-original.png* (or any unique name of your choosing).
- 3. Copy the desired .png image to the folder above.
- 4. Rename it Banner.png.
- 5. Return to the Management Portal and refresh your browser (CTRL+F5 or F12) to display the changes.

Note: The image must be a .png format. Using any other format will cause an error.

**Tip:** The default Keyfactor logo size is 144 x 47 pixels. If you choose a different sized image, the spacing on the browser screens will change.

### 2.2.1.2 Keyfactor Command Appsetting.json Files

Select configuration settings for Keyfactor Command can be found in appsetting.json files within each area subdirectory of your Keyfactor Command installation (e.g. /WebConsole/Configuration/appsettings.json). There are settings that are unique to just one file (for example, connection settings for the orchestrator API) and settings that can be find in all of the files (for example, SQL retry settings). When a setting is found across all files, it should typically be configured identically across all files. For more information, see:

- Keyfactor Command WebConsole Services on page 786
- Keyfactor Command Claims Proxy Services on page 775
- Keyfactor Command Web Agent Services on the next page
- Keyfactor Command Keyfactor API on page 777

- Keyfactor Command Service Job Settings on page 778
- Keyfactor Command Changing SQL Retry Settings on page 787

### **Keyfactor Command Web Agent Services**

The WebAgentServices appsettings.json configuration file allows you to change default orchestrator API installation configuration settings.

To update the appsettings.json file:

- 1. Navigate to the WebAgentServices/Configuration folder on your server (located by default at: C:\Program Files /Keyfactor/Keyfactor Platform/).
- 2. Browse to open the *appsettings.json* file in a text editor (e.g. Notepad) and adjust the values as needed.
- 3. Save the files.

Table 77: Appsetting.json File Parameters - WebAgentServices

Setting	Description
ActiveDirectoryEnforced	This should be set to false if you are not using Active Directory. An IIS reset will be required to apply this setting if you change it.
CheckAuthCertificateRevocationStatus	Enter <i>true</i> to check the revocation status of the certificate provided for client certificate authorization, if being used, otherwise, enter <i>false</i> . The default is <i>true</i> .
ExtensionsDirectory	Enter the file path to the extensions to be loaded by the extension loader (for registration handler, workflow step, etc support). The default value is <i>Extensions</i> (translates to: <i>C:/Program Files/Keyfactor/Keyfactor Platform/WebAgentServices/Extensions</i> )
MaxRequestSizeKb	This application setting is only used for the Orchestrator CA Sync controller. It is used to configure the CA sync batch size. We used to just grab the maximum request size from the IIS configuration settings, but that can no longer be done in .NET 6. The default is 5000.
NLogConfigFile	Enter the file path to the Nlog_Orchestrators.config file.  The default is C:/Program Files\Keyfactor/Keyfactor Platform/WebAgentServices/Configuration

Setting	Description		
SqlRetryConfiguration	SQL retry settings (seeKeyfactor Command Changing SQL Retry Settings on page 787 for more information).		
	Setting	Description	
	NumberOfTries	The number of times it will try the connection before an exception is thrown	
	DeltaTime	The preferred gap time (in seconds) to delay before retry	
	MaxTimeInterval	The maximum gap time (in seconds) for each delay time before retry	
IdpInitializationTimeoutSeconds:		econds) used to make sure all are available before we allow	

```
{
  "ActiveDirectoryEnforced": true,
  "CheckAuthCertificateRevocationStatus": "true",
  "ExtensionsDirectory": "Extensions",
  "MaxRequestSizeKb": "5000",
  "NLogConfigFile": "Configuration\\NLog_Orchestrators.config",
  "IdpInitializationTimeoutSeconds": 10
  "SqlRetryConfiguration": {
     "NumberOfTries": "5",
     "DeltaTime": "00:00:00.5",
     "MaxTimeInterval": "00:02:00"
  }
}
```

Figure 406: Sample WebAgentServices Appsettings.json File

# **Keyfactor Command Claims Proxy Services**

The new ClaimsProxy appsettings.json configuration file allows you to view or modify the configuration settings for the Claims Proxy service.

To update the appsettings.json file:

- 1. Navigate to the ClaimsProxy/Configuration folder on your server (located by default at: CC:\Program Files\Keyfactor\Keyfactor Platform\ClaimsProxy\Configuration).
- 2. Browse to open the *appsettings.json* file in Notepad++ and adjust the values as needed as per Table 78: Appsetting.json File Parameters ClaimsProxy.
- 3. Save the file.

Table 78: Appsetting.json File Parameters - ClaimsProxy

Setting	Description		
NLogConfigFile	Enter the file path to the Nlog_Orchestrators.config file. The default is C:/Program Files\Keyfactor/Keyfactor Platform/WebAgentServices/Configuration		
ExtensionsDirectory	Enter the file path to the extensions to be loaded by the extension loader (for registration handler, workflow step, etc support). The default value is Extensions (translates to: C:/Program Files/Keyfactor/Keyfactor Platform/WebAgentServices/Extensions)		
SqlRetryConfiguration	SQL retry settings (see Keyfactor Command Changing SQL Retry Settings on page 787 for more information).		
	Setting	Description	
	NumberOfTries	The number of times it will try the connection before an exception is thrown	
	DeltaTime	The preferred gap time (in seconds) to delay before retry	
	MaxTimeInterval	The maximum gap time (in seconds) for each delay time before retry	
ReverseProxy	This setting should only be changed on advice and guidance from Keyfactor Support.		
Clusters	Clusters address field is populated by the URL for the API that is entered on the config wizard orchestrators tab and is automatically added to this file when the config wizard is saved.		

```
"NLogConfigFile": "Configuration\\NLog ClaimsProxy.config",

        }
      }
    }
}
```

Figure 407: Sample ClaimsProxy Appsettings.json File

### **Keyfactor Command Keyfactor API**

The KeyfactorAPI appsettings.json configuration file allows you to view or change the Keyfactor Command Keyfactor API installation configuration settings.

To update the appsettings.json file:

- 1. Navigate to the KeyfactorAPI/Configuration folder on your server (located by default at: C:\Program Files\Keyfactor\Keyfactor Platform\KeyfactorAPI\Configuration).
- 2. Browse to open the *appsettings.json* file in a text editor (e.g. Notepad) and adjust the values as needed.
- 3. Save the files.

Table 79: Appsetting.json File Parameters - KeyfactorAPI

Setting	Description	
NLogConfigFile	Enter the file path to the Nlog_KeyfactorAPI.config file. The default is C:/Program Files\Keyfactor/Keyfactor Platform/KeyfactorAPI\Configuration)	
ExtensionsDirectory	Enter the file path to the extensions to be loaded by the extension loader (for registration handler, workflow step, etc support). The default value is Extensions (translates to: C:/Program Files/Keyfactor/Keyfactor Platform/KeyfactorAPI/Extensions)	
ActiveDirectoryEnforced	This should be set to false if you are not using Active Directory. An IIS reset will be required to apply this setting if you change it.	
SqlRetryConfiguration	SQL retry settings (see Keyfactor Command Changing SQL Retry Settings on page 787 for more information).	
	Setting	Description
	NumberOfTries	The number of times it will try the connection before an exception is thrown

     "MaxTimeInterval": "00:02:00"
}
```

Figure 408: Sample KeyfactorAPI Appsettings.json File

### **Keyfactor Command Service Job Settings**

The Service appsettings.json file allows you to view or change the Keyfactor Command Service installation and configuration settings. By default, the Keyfactor Command Service job sets all service jobs to run based on the configuration wizard setting (see *Install the Main Keyfactor Command Components on the Keyfactor Command Server(s): Service Tab* in the *Keyfactor* 

Command Server Installation Guide). The setting for select service jobs can be changed in the appsettings.json file.

To update the appsettings.json file for service configuration:

- 1. Navigate to the Service/Configuration folder on your server (located by default at: *C:\Program Files\Keyfactor\Keyfactor Platform\Service\Configuration*).
- 2. Browse to open the *appsettings.json* file in a text editor (e.g. Notepad) and adjust the values as needed as per <u>Table 81: Keyfactor Command Jobs Services</u> and <u>Table 80: Keyfactor Command Services Configuration Settings</u>

```
"NLogConfigFile": "NLog TimerService.config",
"ExtensionsDirectory": "Extensions",
"ActiveDirectoryEnforced": true,
"ConcurrentWorkflows": 1000,
"LockTimeout": 5000,
"MetadataGeneration": {
 "Version": 1,
 "Parallelism": 8,
  "ProgressInterval": "00:07:00"
},
"SqlRetryConfiguration": {
  "NumberOfTries": "5",
  "DeltaTime": "00:00:00.5",
  "MaxTimeInterval": "00:02:00"
"Jobs": {
 "BulkAuditProcessing": true,
 "MetadataGeneration": true,
 "PrivateKeyCleanup": true,
  "PurgeAuditHistory": true,
 "EndpointHistory": true,
  "ReportingCleanup": true,
  "ScheduleSslJobs": true,
  "SuspendedWorkflows": true,
  "SyncTemplates": true,
  "StatsUpdate": true,
  "WorkflowCleanup": true,
 "CAHealth": true,
  "CAThreshold": true,

```

Figure 409: Appsettings.json File for TimerService Settings

3. Save the file.

Table 80: Keyfactor Command Services Configuration Settings

Setting	Description	
NLogConfigFile	Enter the file path to the Nlog_KeyfactorAPI.config file. The default is C:/Program Files\Keyfactor/Keyfactor Platform/KeyfactorAPI\Configuration)	
ExtensionsDirectory	Enter the file path to the extensions to be loaded by the extension loader (for registration handler, workflow step, etc support). The default value is Extensions (translates to: C:/Program Files/Keyfactor/Keyfactor Platform/KeyfactorAPI/Extensions)	
ActiveDirectoryEnforced		se if you are not using Active Directory. An IIS apply this setting if you change it.
SqlRetryConfiguration	SQL retry settings (see on page 787 for more in	Keyfactor Command Changing SQL Retry Settings formation).
	Setting	Description
	NumberOfTries	The number of times it will try the connection before an exception is thrown
	DeltaTime	The preferred gap time (in seconds) to delay before retry
	MaxTimeInterval	The maximum gap time (in seconds) for each delay time before retry
MetadataGeneration		
motadata donoration	Setting	Description
	Version	This timer service job iterates over the certificates in the database, looks for avalue less than the version set here, and if true, sets the certs' property with the version number specified here.
	Parallelism	The how many threads of the job run simultaneously.
	ProgressInterval	How often (in milliseconds) the work from cache is saved to the database.
LockTimeout	The wait time in milliseconds to acquire a lock on a job for High Availability.	

Table 81: Keyfactor Command Jobs Services

Туре	Service	Description	Notes
Maintenance	BulkAuditProcessing	Periodically add audit log entries for large jobs. Most audit log entries are added immediately at the time the activity generating the audit log takes place. However, some large jobs that might generate heavy server load (e.g. bulk revocation) save the audit log entries in a temporary location to reduce server load and then they are added to the audit log by this periodic job.	This job runs every 10 minutes.
Maintenance	MetadataGeneration	Periodically generate and assign metadata to certificates when they are imported into Keyfactor Command using a custom metadata extension.	This job runs every 15 minutes.
Maintenance	PrivateKeyCleanup	Periodically remove any stored private keys in the Keyfactor Command database that have expired and are eligible for deletion.	This job runs daily at 1:00 am. For more information about stored private keys, see Status Tabon page 24.
Maintenance	PurgeAuditHistory	Periodically remove any audit log history in the Keyfactor Command database that has expired and is eligible for deletion.	This job runs monthly on the first day of the month at 2:00 am.  For more information, see Application Settings: Auditing Tab on page 609.  Only audit logs belonging to unprotected categories are eligible for deletion.
Maintenance	EndpointHistory	Periodically remove any SSL endpoint history in the	This job runs daily at 1:00 am.

Туре	Service	Description	Notes
		Keyfactor Command database that is eligible for deletion, based on the setting in Application Settings:  Auditing Tab on page 609 (SSL > Retain SSL Endpoint History (days)).	
Maintenance	ReportingCleanup	Periodically remove records from temporary files generated while running reports.	This job runs daily at midnight.
Maintenance	ScheduleSSLJobs	Periodically identify and schedule SSL discovery and monitoring jobs.	This job runs every 5 minutes.
Other	SuspendedWorkflows	Periodically attempt to continue all suspended workflows that may be eligible to continue but have not done so due to locking conflicts. A locking conflict may occur if two users attempt to provide input to a workflow instance (e.g. approve a request) at exactly the same time.	This job runs daily at midnight.
Maintenance	SyncTemplates	Periodically synchronize certificate templates from the source (e.g. Active Directory) to pick up new templates.	This job runs every hour.
Maintenance	StatsUpdate	Periodically run the Microsoft SQL update stat- istics function in the Keyfactor Command data- base.	This job runs monthly on the first day of the month at 1:00 am.
Maintenance	WorkflowsCleanup	Periodically remove any completed workflow instances (both successful and failed) in the Keyfactor Command database that have aged X number of days	This job runs daily at midnight.

Туре	Service	Description	Notes
		past the completion date (last modified date), where X is defined by the Workflow Instance Cleanup Days application setting (see Application Settings: Console Tab on page 603). The default value is 14 days.	
Alerts	CAHealth	Periodically send email alerts when a CA is not responding.	The schedule for this is user configurable (see Certificate Authority Monitoring on page 379).
Alerts	CAThreshold	Periodically send email alerts when a CA is issuing certificates or experiencing issuance failures outside of the established norms.	The schedule for this is user configurable (see Advanced Tab on page 366).
Alerts	CRL	Periodically send email alerts for certificate revocation lists (CRLs) that are approaching expiration.	The schedule for this is user configurable (see Adding or Modifying a Revocation Monitoring Location on page 211).
Alerts	ExpirationAlerts	Periodically send email alerts for certificates approaching expiration.	The schedules for these are user configurable. See Configuring an Expiration  Alert Schedule on page 171.
Alerts	IssuedAlerts	Periodically send email alerts (typically to certificate requesters) for certificate requests made using a certificate template that requires manager approval that have been approved.	The schedule for this is user configurable (see Configuring an Issued Request Alert Schedule on page 193)
Alerts	PendingAlerts	Periodically send email alerts (typically to certificate	The schedules for these are user config-

Туре	Service	Description	Notes
		approvers) for certificate requests made using a certificate template that requires manager approval.	urable. See Configuring a Pending Request Alert Schedule on page 183.
Other	Queryltems	Periodically populates a cache of which certificates are in which collection in the database. This is used in for the workflow step types:  Certificate Entered Collection and Certificate Left  Collection	Runs every 10 minutes (see Workflow Definition Operations on page 235)
Other	Reporting	Deliver regularly scheduled reports via email or saved to a file system.	The schedules for these are user configurable (see Reports on page 91).
Alerts	SSHKeyRotationAlerts	Periodically send email notifications to SSH key users and/or administrators when a key is nearing the end of the key lifetime.	The schedule for this is user configurable (see Configuring a Key Rotation Alert Schedule on page 206).
Alerts	AgentNotificationAlert	Periodically runs a job that checks if an orchestrator has not checked in between job runs and sends an email notification as per settings in Application Settings: Agents Tab on page 615.	This is configurable at Application Settings: Agents Tab on page 615
Certificate Authority	CASync	Periodically synchronize certificates from certificate authorities.	The schedules for this are user configurable (see Certificate Authorities on page 350).
Alerts	CollectionQueryAlerts	Periodically update the temporary tables that store information on which certificates are in which certificate collections. These temporary tables (caches) are used to support faster	This value is user configurable with an application setting (see Application Settings:  Console Tab on page 603). The default is 20 minutes.

Туре	Service	Description	Notes
		processing of some systems.	
n/a	ConcurrentWorkflows	Sets the batch size used when suspended workflows are run by the Keyfactor Command service. Also used when running certificate entered collection and certificate left collection workflows to limit the number of certificates flowing through the workflow for each instance of the workflow initiated by the service.	The default value is 1000.

# **Keyfactor Command WebConsole Services**

The WebConsole appsettings.json configuration file allows you to view or change the Keyfactor Command Management Portal installation configuration settings.

To update the appsettings.json file:

- 1. Navigate to the WebConsole/Configuration folder on your server (located by default at: C:\Program Files /Keyfactor/Keyfactor Platform/Console/Configuration).
- 2. Browse to open the *appsettings.json* file in a text editor (e.g. Notepad) and adjust the values as needed.
- 3. Save the files.

Table 82: Appsetting.json File Parameters - WebPortalServices

Setting	Description
NLogConfigFile	Enter the file path to the Nlog_Orchestrators.config file. The default is C:/Program Files\Keyfactor/Keyfactor Plat-form/WebConsole/Configuration
ExtensionsDirectory	Enter the file path to the extensions to be loaded by the extension loader (for registration handler, workflow step, etc support). The default value is Extensions (translates to: C:/Program Files/Keyfactor/Keyfactor Platform/WebConsole/Extensions)
ActiveDirectoryEnforced	This should be set to false if you are not using Active Directory. An IIS reset will be required to apply this setting if you change it.

Setting	Description	
SqlRetryConfiguration	SQL retry settings (see Keyfactor Command Changing SQL Retry Settings below for more information).  Setting Description	
	NumberOfTries	The number of times it will try the connection before an exception is thrown
	DeltaTime	The preferred gap time (in seconds) to delay before retry
	MaxTimeInterval	The maximum gap time (in seconds) for each delay time before retry

```
"NLogConfigFile": "Configuration\\NLog_Portal.config",
"ExtensionsDirectory": "Extensions",
"ActiveDirectoryEnforced": true,
"SqlRetryConfiguration": {
  "NumberOfTries": "5",
  "DeltaTime": "00:00:00.5",
  "MaxTimeInterval": "00:02:00"
},
```

Figure 410: Sample WebConsole Services Appsettings.json File

## **Keyfactor Command Changing SQL Retry Settings**

The settings for SQL retries are configured in the appsettings.json file in each of the Keyfactor Program folders: Service, WebConsole, ClaimsProxy, WebAgentServices, and KeyfactorAPI (located by default at: C:\Program Files\Keyfactor\Keyfactor\Platform/...). Any changes must be made to match in each appsettings.json file.

To update the appsettings.json file for SQL configuration:

- 1. Navigate to the /Configuration folder on your server for each of the Keyfactor Program folders.
- 2. Browse to open the *appsettings.json* file in a text editor (e.g. Notepad) and adjust the values as needed.
- 3. Save the files.

Table 83: Appsetting.json file - SQL Retry Parameters

Setting	Description
NumberOfTries	The number of times it will try the connection before an exception is thrown
DeltaTime	The preferred gap time (in seconds) to delay before retry
MaxTimeInterval	The maximum gap time (in seconds) for each delay time before retry

```
"NLogConfigFile": "Configuration\\
"ExtensionsDirectory": "Extensions",

"ActiveDirectoryEnforced": true,

"SqlRetryConfiguration": {
  "NumberOfTries": "5",
  "DeltaTime": "00:00:00.5",
  "MaxTimeInterval": "00:02:00"
```

Figure 411: Sample Appsettings.json File for SQL Retry Settings

#### 2.2.1.3 Keyfactor Command Service Executable

By default, the Keyfactor Command Service is run using the CMSTimerService.exe executable. This executable is found in the following directory, by default:

```
C:\Program Files\Keyfactor\Keyfactor Platform\Service
```

This executable file does not shipped in a signed state. In environments where this is a concern, it is possible to change the Keyfactor Command Service to instead run using the CMSTimerService.dll. This file does ship in a signed state.

To make this change:

1. On the Keyfactor Command server, open a command prompt (NOT a PowerShell window) using the "Run as Administrator" option and type the following (h:

```
sc config KeyfactorTimerJobService binPath= "dotnet \"C:\Program
Files\Keyfactor\Keyfactor Platform\Service\CMSTimerService.dll\""
```

**Note:** If your Keyfactor Command is installed in a different location than the default, change this path to reflect your installation location.

- 2. Once the command completes, you should receive a success message:
  - [SC] ChangeServiceConfig SUCCESS

3. To confirm that the Keyfactor Command Service will now run as the dll, you can open the Properties for the service in the services.msc and view the *Path to executable* field to confirm that it ends with the dll rather than the exe. Note that this field should also begin *dotnet* \ once you switch to the dll.

Figure 412: Switch the Keyfactor Command Service to Run as the CMSTimerService.dll

4. Restart the Keyfactor Command Service.

## 2.2.1.4 Configuring Key Recovery for Keyfactor Command

The following instructions for configuring CA-level key recovery within Keyfactor Command assume that your Microsoft CA is already configured for key recovery and that you have the key recovery agent (KRA) certificate available as a PFX file for import on the Keyfactor Command administration server. Instructions for configuring key recovery on a Microsoft CA are beyond the scope of this guide.

**Tip:** CA-level key recovery is supported for Microsoft CAs to allow recovery of private keys for certificates enrolled outside of Keyfactor Command. CA-level key archiving is not supported for enrollments done through Keyfactor Command. CA-level key recovery is not supported for EJBCA CAs. For enrollments done through Keyfactor Command for either Microsoft or EJBCA CAs, use Keyfactor Command private key retention (see <a href="Details Tab on page 388">Details Tab on page 388</a>).

To configure your Keyfactor Command administration server to support key recovery:

1. Login on the Keyfactor Command administration server as the service account under which the Keyfactor Command application pool is running and open a command prompt. Alternately, if you

have previously logged on as this service account and created a user profile for the service account, you can open a command prompt as the service account using Shift-Right-Click and choose "Run as different user". Within the command prompt type the following to open the certificates MMC for the service account user:

certmgr.msc

2. Import the KRA PFX file into the service account user's personal certificate store.

This process needs to be repeated using the KRA certificate(s) from each CA for which you want to enable recovery within the Management Portal.

**Note**: To provide additional security over KRA private key(s), Keyfactor strongly recommends the use of a Hardware Security Module (HSM) such as the Thales NetHSM.

**Tip:** CA-level key recovery is not supported for EJBCA CAs. Instead, use private key retention within Keyfactor Command (see Details Tab on page 388).

### 2.2.2 SSH Reference

Please see the pages indicated for more detailed information about those specific SSH topics.

- SSH-Bash Orchestrator Job History Warning Resolution below
- SSH-SSSD Case Sensitivity Flag on the next page

#### 2.2.2.1 SSH-Bash Orchestrator Job History Warning Resolution

Previously, it was unlikely the Bash orchestrator would fail during a sync job once it was configured correctly. With the introduction of SSSD support, there is additional validation the orchestrator must do as it applies the configured state that is being passed down from the server. Namely, we must validate that:

- The home directory known by SSSD falls directly underneath the LogonHomeDirectories setting value.
- The location of the authorized\_keys directory as understood by SSHD is the home directory known by SSSD.
- The given logon must be resolvable in SSSD.

In the case where one or more of these criteria aren't valid assumptions, the logon won't be created or its keys will not be published. In this case, a message is returned on the Orchestrator Jobs page for the sync job with a Warning result (see <u>Job History on page 517</u>). These messages will continue to be returned until all issues are resolved. The intended resolution for this issue depends on the issue itself. See <u>Table 84: Bash Orchestrator Job History Warning Resolution</u> for examples of possible solutions to issues.

Table 84: Bash Orchestrator Job History Warning Resolution

Issue	Resolution	
The home directory known by SSSD doesn't fall directly underneath the LogonHomeDirectories setting value.	Change the logon's home directory in the identity source that SSSD is pulling the identity from to be exactly one directory level under the configured value for the <i>LogonHomeDirectories</i> setting.	
The location of the authorized_keys directory as understood by SSHD is not the home directory known by SSSD.	Modify the local SSHD configuration to ensure that the authorized_keys file can be resolved to the user's home directory and that the user's home directory is nested directly beneath the bash orchestrator's LogonHomeDirectories setting value.	
A given logon cannot be resolved in SSSD.	Tip: The bash orchestrator will treat SSSD logon names as case sensitive despite the fact that the look up will succeed regardless of case sensitivity. Ensure that the logon name entered matches the logon name as presented by SSSD (see SSH-SSSD Case Sensitivity Flag below).	
	<ul> <li>If the logon is found not be a valid logon on the server, delete the logon on the Keyfactor Command server and try adding the correct one.</li> </ul>	

### 2.2.2.2 SSH-SSSD Case Sensitivity Flag

As of RHEL 6 (SSSD package 1.6), a case\_sensitive option was added to the valid list of parameters for a given provider in the /etc/sssd/sssd.conf file. When this value is false, querying SSSD for a given user will return the username in all lower case, regardless of the casing in Active Directory. This value can be set to *Preserving*, which will return the casing used in the username in Active Directory.

The case sensitivity flag is important since attempting to create a new SSH logon in Keyfactor Command (see <u>Adding Logons on page 586</u>) requires that the username is entered as it appears in SSSD, regardless of this setting's value. Using *Preserving* makes the logons look like they do in Active Directory so it may be a less confusing experience for system administrators or those in charge of provisioning the accounts. If this flag is set to false, SSSD will return the name as all lower case characters to preserve POSIX compliance, which is how usernames will need to be entered into Keyfactor Command to create them.

**Note:** Besides the case-sensitive option setting, there are other SSSD settings that can affect how the username is presented which are not covered in this discussion.

Run the command below in your environment to determine how the username should be formatted.

A

Important: This value should not be changed once home directories have already been created on the server, even if done so prior to installing the Bash Orchestrator. Doing so will result in a conflict between Keyfactor Command's understanding of a login's casing and SSSD's. You will then receive an error until this logon is removed or its home directory is updated on the target server.

**Example:** User *BBROWN@keyexample.com* has a home directory /home/BBROWN@keyexample.com that is out of compliance with SSSD known directory /home/bbrown@keyexample.com. The resolution of this error, in the case of the case\_sensitivity property, is to either update the logon's home directory in AD or remove the logon's home directory on the local server and re-add it through Keyfactor Command.

**Example:** It is also possible for SSSD's understanding of a logon's home directory or account name to change if name of the domain changes in the SSSD config file. In this case, it's expected that the logon is removed from Keyfactor Command, in addition to its home directory on the Linux server, and re-added.

# 2.2.3 System Alerts

The System Alerts panel appears at the top of the Management Portal page just below the menu bar to display any errors or warnings found within Keyfactor Command. Click on the alerts indicator to toggle the System Alerts panel open/close. Warnings indicate things that may be of concern and appear in yellow. Errors indicate things that may be more urgent and appear in red. Click on the link included at the bottom of the system alert to be taken to the relevant page in the Management Portal to make the required configuration changes or corrections, if applicable. Some examples of conditions for which the system alerts appear include:

- The Keyfactor Command license is approaching expiration (warning)
- The Keyfactor Command license has expired (error)
- · Certificate store job failures
- SSL scanning job failures
- NTLM authentication has been detected (and thus enrollment requests won't succeed)

Some system alerts are global and will appear on the system alerts panel regardless of where you are in the Management Portal. Other system alerts (such as some related to SSL scanning) are specific to a particular Management Portal page and will only appear when you are on that page.

Figure 414: Management Portal Errors and Warnings

# 2.2.4 Log Monitoring

Logging information from your Keyfactor Command implementation is available in a variety of places:

- Dedicated text files for each application are written to the server.
   The logs for the various components of Keyfactor Command are saved, by default, under the local folder C:\Keyfactor\logs\.... For more information, see Editing NLog on page 796.
- The Windows event log on the Keyfactor Command server.
   For more information, see Keyfactor Command Windows Event IDs on page 806.
- The Audit Log in the Keyfactor Command Management Portal.
   Logs of auditable changes that affect your Keyfactor Command implementation—e.g. creation, change, or deletion of a record in an area of the product such as Certificates or Security—are viewable in the Management Portal, are output to a text file on the Keyfactor Command server, and can optionally be collected to a separate server for analysis with a centralized logging solution. For more information, see Audit Log on page 718.

In addition, transactions coming into the Keyfactor Command Management Portal are written into the IIS logs. For the most part, there is no need to look in the IIS logs unless you encounter a problem you need to troubleshoot. However, it is a good practice to monitor the text logs, the audit log, and the Windows event logs to make sure the system is operating smoothly and no errors are occurring.

By default, 10 main text logs are retained before the oldest ones are automatically deleted. Logs are rotated daily or when they reach a maximum file size, whichever comes first. Depending on the volume of log information you're generating, 10 logs may cover 10 days or a much shorter period. If you're using a centralized logging solution that runs daily to copy these to another location for analysis, the default log configuration of 10 logs with a maximum file size of 50 MB may be a sufficient retention policy. If you intend to analyze them in place on the Keyfactor Command server, you may wish to extend this retention setting.

In both the text-based logs and the Windows event logs, errors will generally appear with a tag of Error. For the text log, an error entry would look something like this, with more information following this line (and perhaps before it) with some further details:

2021-08-16 10:00:21.7105 CSS.CMS.CA.Client.CertificateAuthority [Error] - An error occurred while reading the CA database.

Some errors may be transitory. For example, a CA synchronization may fail because a CA was down for maintenance and then succeed on the next try when the server is back up. If you find errors in your logs and need help tracking down their cause, contact Keyfactor support (<a href="mailto:support@key-factor.com">support@key-factor.com</a>).

When troubleshooting an error, it may be helpful to turn up the logging level in the Nlog.config file relevant to the component of interest to *debug* or *trace*. However, this can result in a large volume of messages that can be hard to wade through. It is sometimes useful to add further filters to the Nlog.config file relevant to the component of interest to filter out log traffic unrelated to the error you are trying to investigate. Some of the NLog files for the various log components contain predefined filters such as:

```
<when condition="ends-with('${logger}', 'WebSecurityContext') and level &lt;
LogLevel.Warn" action="Ignore" />
<when condition="ends-with('${logger}', 'AlertsController') and level &lt;
LogLevel.Warn" action="Ignore" />
<when condition="ends-with('${logger}', 'WebPrincipal') and level &lt; LogLevel.Warn"
action="Ignore" />
<when condition="ends-with('${logger}', 'CertStoreController') and level &lt;
LogLevel.Warn" action="Ignore" />
```

These filter out messages that contain the referenced string (e.g. WebSecurityContext) at the end of the log source string (e.g. CSS.CMS.Web.Security.WebSecurityContext) but only for messages that are at an Info, Debug or Trace level (less than Warn) as in this log line:

```
2021-08-11 04:38:04.0366 CSS.CMS.Web.Core.Security.WebSecurityContext [Trace] - User 'KEYEXAMPLE\ggant' (Cached) has area permission 'Reports_Read' as requested by 'Execute'
```

You can add more lines like this that do things like filter out the periodic report cleanup process, for example:

```
<when condition="ends-with('${logger}', 'ReportCleanupManager') and level &lt;
LogLevel.Warn" action="Ignore" />
```

You can also filter out messages based on all or part of the message. Say you want to look at CA synchronization messages, but want to eliminate some of the chatter related to that. You don't want to filter out all the CA synchronization source messages in that case, but you might choose to get rid of entries like this:

```
2020-05-20 08:41:00.0487 CSS.CMS.CA.Client.CertificateAuthorityConnector [Trace] - Fetch succeeded
```

You can do that with a filter that looks like this:

```
<when condition="starts-with('${message}', 'Fetch succeeded') and level &lt;
LogLevel.Info" action="Ignore"/>
```

**Note:** For more information on how to make changes to your NLog configuration see <u>Editing</u> NLog below

Some informational, warning, and error messages generated by Keyfactor Command are coded in a manner to allow them to be redirected for output to the Windows Application event log. If you redirect these messages from being output to the event log to a file instead, they look something like:

2021-08-02 04:54:00.2260 CSS.CMS.Service.Jobs.CASync.LocalCASyncJob-EVENT [Info] - eventID=200&categoryID=2&eventMessage=Beginning+Full+synchronization+of+Certificate+Auth ority%3a+%27corpca02.keyexample.com %5cCorpIssuing2.+Last+scan+time%3a+11%2f10%2f2020+10%3a20%3a00+AM%2c+last+row+read%3a+0% 27

The -EVENT tag (highlighted in red, above) is what codes these messages for redirection to the event log. There are two configuration lines in the NLog.config files for the various log components that relate to Windows event log redirection—the first formats the data correctly for event log usage and assigns a source to the messages while the second captures all the messages coded -EVENT, prevents them from going to the regular text log, and redirects them to the event log for all messages at info, warning or error level. Debug and trace level messages are not designed to be output to the event log. To reduce the volume of messages to the event log, you can change minlevel="Info" to minlevel="Warn" or minlevel="Error". Be aware that if you do this, more verbose messages (e.g. info level messages) will fall through to the text-based log.

Figure 415: Nlog Configuration for Windows Event Logging

By default, messages redirected to the event log are marked with a source of *Keyfactor Command* for Keyfactor Command server, *Keyfactor Service* for the Keyfactor Command Service, and *Keyfactor Orchestrators* or *Keyfactor Orchestrator* for the Keyfactor Universal Orchestrator.

#### 2.2.4.1 Editing NLog

Keyfactor Command provides extensive logging for visibility and troubleshooting. For more information about troubleshooting, see <a href="Troubleshooting">Troubleshooting</a> on page 823.

By default, Keyfactor Command outputs logging information to both the Windows event log and the local file system, places file system log files in the C:\Keyfactor\logs directory, generates file system logs at the *Info* logging level, and stores the primary file system logs for two days before deleting them. If you wish to change these defaults you can open the configuration file for each type of log on each Keyfactor Command server where you wish to adjust logging, and edit the file in a text editor

(e.g. Notepad) using the "Run as administrator" option. Each Keyfactor component has its own NLog configuration file and NLog logging output path.

**Note**: By default, the filename for each component log is unique. This allows you to isolate and research issues on a component-by-component basis by viewing a specific log file. Alternatively, you may wish to change the default output filename to be the same for all logging components so all activity is reported in a single log file. You will note that the default Audit and Alert file names for each component (for those components that log audits or alerts) are the same so that all activity is logged in the same file across the platform for this reason.

**Tip:** If you use the default naming convention, and want to review an event that happened in the Management Portal, for instance, you would look in the Command\_API\_Log.txt and/or the Command\_Portal\_Log.txt.

**Important:** If you choose to name the log files the same across the platform, it is recommended that you also set the **maxArchiveFiles** values the same in each Nlog config file. If there is a different value for **maxArchiveFiles** for files with the same filename/location, the smallest value will override all others.

To make changes to your NLog configuration:

- 1. On each Keyfactor Command server where you wish to adjust logging, open a text editor (e.g. Notepad) using the "Run as administrator" option.
- 2. In the text editor, browse to open the desired Nlog.config file for the appropriate Keyfactor component (see <u>Table 85: NLog.config Files for Keyfactor Command</u>). The files are located in application subdirectories under the installed directory, which is the following by default:

C:\Program Files\Keyfactor\Keyfactor Platform

- 3. Each Nlog.config file may have a slightly different layout than the portal example shown here, but it will contain many of the fields highlighted in the below figure. The fields you may wish to edit are:
  - The path and file name of the active Keyfactor Command log file:

```
fileName="C:\Keyfactor\logs\Command_Portal_Log.txt"
fileName="C:\Keyfactor\logs\Command_API_Log.txt"
fileName="C:\Keyfactor\logs\Command_Service_Log.txt"
fileName="C:\Keyfactor\logs\Command_OrchestratorsAPI_Log.txt"
```

```
fileName="C:\Keyfactor\logs\Command_Configuration_Log.txt"
fileName="C:\Keyfactor\logs\Command ClaimsProxy Log.txt"
```

Important: If you choose to change the path for storage of the log files, you will need to create the new directory (e.g. D:\KeyfactorLogs) and grant both the service account under which the Keyfactor Command Service is running and the service account under which the IIS application pool for Keyfactor Command is running full control permissions on this directory. These roles may be served by the same service account.

• The path and file name of previous days' log files:

```
archiveFileName="C:\Keyfactor\logs\Command_Portal_Log_Archive_{#}.txt"

archiveFileName="C:\Keyfactor\logs\Command_API_Log_Archive_{#}.txt"

archiveFileName="C:\Keyfactor\logs\Command_OrchestratorsAPI_Log_Archive_{#}.txt"

archiveFileName="C:\Keyfactor\logs\Command_Configuration_Log_Archive_{#}.txt"

archiveFileName="C:\Keyfactor\logs\Command_Configuration_Log_Archive_{#}.txt"
```

Keyfactor Command rotates log files daily and names the previous files using this naming convention.

The path and file name of the active log file for alerting events:

```
fileName="C:\Keyfactor\logs\Command_Alert_Log.txt"
```

This entry is found on in the NLog.cong files on servers with the Keyfactor Command Service installed. Info level messages are written to this log whenever alerts (certificate expiration, pending certificate request, issued certificate, denied certificate request, or revocation monitoring) are run either as scheduled tasks or as tests. The log messages include the type of alert (e.g. expiration alert), the recipient of the alert (if an email was scheduled to be sent), and the alert subject line. You can change the level of logging in the log line that references writeTo="alertlogfile". These logs are generated separately from the general events to allow for separate tracking and log shipping of alerting events. By default, the alert log filename/location for all components is the same to allow for a central source for tracking alert events across the platform.

**Note**: This entry is not found in NLog\_Configuration.config and NLog\_ClaimsProxy.config files.

• The path and file name of previous days' Keyfactor Command log files for alert events:

archiveFileName="C:\Keyfactor\logs\Command\_Alert\_Log\_Archive\_{#}.txt"

**Note:** This entry is not found in NLog\_Configuration.config and NLog\_ClaimsProxy.config files.

• The path and file name of the active log file for auditable events:

fileName="C:\Keyfactor\logs\Command\_Audit\_Log.txt"

These logs are generated separately from the general events to allow for separate tracking of auditable events. By default, the audit log filename/location for all components is the same to allow for a central source for tracking auditable events across the platform.

Note: This entry is not found in NLog\_ClaimsProxy.config files.

• The path and file name of previous days' Keyfactor Command log files for auditable events:

archiveFileName="C:\Keyfactor\logs\Command\_Audit\_Log\_Archive\_{#}.txt"

**Note**: This entry is not found in NLog\_ClaimsProxy.config files.

 The level of log detail that should be generated for alert events and written to the alert logs:

name="EmailAlertLogger" minlevel="Info" writeTo="alertlogfile"

**Note:** This entry is not found in NLog\_Configuration.config and NLog\_ClaimsProxy.config files.

• The number of archive files to retain before deletion:

maxArchiveFiles="10"

This field is listed multiple times in most NLog.config files on a server with the Keyfactor Command Service installed—once for the main logging section, once for the alert logging section (if applicable), and once for the audit logging section. The default number of files to retain is 10 for the main log and the synchronization log but 14 for the alert log and audit

log. The alert and audit logs are small by default, and retaining a larger number of them shouldn't create a disk space issue.

• The maximum file size of each log file:

```
archiveAboveSize="52428800"
```

Once a log file reaches this size (50 MB by default), it will be rotated to archive even if the end of the day has not been reached.

• The level of log detail that should be generated:

```
name="*" minlevel="Info" writeTo="logfile"
```

This line applies to all the logs in the file. The default *Info* level logs error and some informational data but at a minimal level to avoid generating large log files. For troubleshooting, it may be desirable to set the logging level to *Debug* or *Trace*. Available log levels (in order of increasing verbosity) are:

- OFF No logging
- ° FATAL Log severe errors that cause early termination
- ERROR Log severe errors and other runtime errors or unexpected conditions that may not cause early termination
- WARN Log errors and use of deprecated APIs, poor use of APIs, almost errors, and other runtime situations that are undesirable or unexpected but not necessarily wrong
- INFO Log all of the above plus runtime events (startup/shutdown)
- DEBUG Log all of the above plus detailed information on the flow through the system
- ° TRACE Maximum log information—this option can generate VERY large log files

```
- Keyfactor expects at least 2 targets to be present: 'logfile' and 'eventLog'. Please do not change the name attribute of these targets
   <target xsi:type="AsyncWrapper" name</pre>
vules>
<!-- Internal ASP.NET logging, off by default -->
<logger name="CSS.CMS.Web.API.SimpleTracer" minlevel="Off" writeTo="LogfileAsync" final="true" />
<logger name="*-EVENT" minlevel="Info" writeTo="eventLog" final="true" />
<logger name="*-AUDIT" minlevel="Info" writeTo="auditlogfile" final="true" />
<logger name="*-AUDIT" minlevel="Info" writeTo="alertlogfile" final="true"/>
<logger name="*-minlevel="Info" writeTo="LogfileAsync">
<filters defaultAction="Log">
     when condition="mas-with('${logger}', 'WebSecurityContext') and level < LogLevel.Warn" action="Ignore" />
<when condition="mas-with('${logger}', 'AlertsController') and level &lt; LogLevel.Warn" action="Ignore" />
<when condition="ends-with('${logger}', 'CertStoreController') and level &lt; LogLevel.Warn" action="Ignore" />
```

Figure 416: Nlog\_KeyfactorAPI.config

4. Change the respective files and save your changes.

Tip: Some of the NLog.config files also contain a few filters that eliminate log messages of certain types from logging at debug and trace level as they can be chatty and may not be helpful except in special cases. You may find it helpful to emulate these with filters of your own when troubleshooting. For example, the following filters are found by default in the Keyfactor API and Management Portal log configurations:

```
<filters defaultAction="Log">
   <when condition="ends-with('${logger}', 'WebSecurityContext') and level < LogLevel.Warn"</pre>
action="Ignore" />
   <when condition="ends-with('${logger}', 'AlertsController') and level < LogLevel.Warn"</pre>
action="Ignore" />
   <when condition="ends-with('${logger}', 'CertStoreController') and level < LogLevel.Warn"</pre>
action="Ignore" />
   <when condition="starts-with('${logger}', 'Microsoft.') and level < LogLevel.Warn" action-</pre>
n="Ignore" />
</filters>
```

You can add additional filters to remove further messages. For example, this configuration shows logs related to reading certificate templates filtered out:

```
<filters defaultAction="Log">
   <when condition="ends-with('${logger}', 'WebSecurityContext') and level < LogLevel.Warn"</pre>
action="Ignore" />
```

The first, for TemplateSecurityReader messages, will filter out log messages such as these:

```
2023-10-11 03:59:15.0183 Keyfactor.ActiveDirectory.PKI.TemplateSecurityReader [Debug] - Template: CorpWebServer 2023-10-11 03:59:15.0183 Keyfactor.ActiveDirectory.PKI.TemplateSecurityReader [Trace] - KEYEXAMPLE\jsmith (S-1-5-21-2996571167-427620427-431932065-1000) mentioned for Enroll 2023-10-11 03:59:15.0183 Keyfactor.ActiveDirectory.PKI.TemplateSecurityReader [Trace] - Access control type is 'Allow'
```

The second, for CertificateTemplateReader, will filter out log messages such as these:

```
2023-10-11 03:59:22.6312 Keyfactor.ActiveDirectory.PKI.CertificateTemplateReader [Debug] - Leaving 'Load' method with 475 certificate template objects from AD 2023-10-11 03:59:22.6312 Keyfactor.ActiveDirectory.PKI.CertificateTemplateReader [Debug] - Creating CertificateTemplate objects 2023-10-11 03:59:22.6312 Keyfactor.ActiveDirectory.PKI.CertificateTemplateReader [Trace] - Adding Certificate Template 'User'.
```

Both these types of messages relate to building the cache of certificate authorities, templates and permissions that Keyfactor Command uses for enrollment. These messages are specific to Microsoft templates; other types of messages are generated for EJBCA templates. The cache is rebuilt every 10 minutes, so these messages will appear every 10 minutes. If you have a large number of templates and/or users granted rights to templates in your environment, the messages can be overwhelming if you enable debug or trace logging and you don't happen to be looking for template information.

Table 85: NLog.config Files for Keyfactor Command

Configuration File	Description
\WebConsole\Configuration\NLog_Portalconfig	The Portal file is for logging any activity to do with the Keyfactor CommandManagement Portal, including users connecting to the portal, loading various pages in the portal, and taking actions.
	Note: Many actions taken in the Keyfactor CommandManagement Portal are carried out using the Keyfactor API and Keyfactor is migrating the product to use the Keyfactor API more and more, so this file will have less and less activity going forward.
\KeyfactorAPI\Configuration\NLog_ KeyfactorAPI.config	The KeyfactorAPI file is the primary file for logging activity related to making requests with the Keyfactor API. Since many of the functions in the Management Portal use the Keyfactor API, this log also includes activity related to running the Management Portal.
\Service\Configuration\NLog_Timer- Service.config	The Timer Service file logs activity related to scheduled and automated events within Keyfactor Command such as CA synchronization, scheduled alerts, and scheduled reports.
\WebAgentServices\Configuration\NLog_ Orchestrators.config	The Orchestrators, or OrchestratorsAPI, file logs activity related to Keyfactor Orchestrators API. Look here for messages related to orchestrators communicating with Keyfactor Command.
\Configuration\NLog_Configuration.config	The Configuration file logs activity related to running the Keyfactor Command configuration wizard only. It may be useful to increase the logging level on this one if you are experiencing installation or upgrade issues.
\ClaimsProxy\Configuration\NLog_Claim- sProxy.config	The ClaimsProxy file logs activity related to using Keyfactor Identity Provider for authentication. Look here for messages related to authenticating to Keyfactor Command using token authentication.
	Note: The ClaimsProxy log offers a further option for extended logging beyond that found for the other logs since the type of messages generated for claims-related issues tend to occur not entirely within the realm of Keyfactor Command. To

Configuration File Description

configure extended logging, look in the targets section of the file for the target of type File:

```
<targets>
   <target xsi:type="AsyncWrapper" name ="Lo-</pre>
ogfileAsync">
      <target xsi:type="File" name="logfile"
fileName="C:\Keyfactor\logs\Command_Claim-
sProxy_Log.txt" layout="${longdate}
${logger} [${level}] - ${message}"
         archiveFileName-
e="c:\Keyfactor\logs\Command_ClaimsProxy_
Log_Archive_{#}.txt" archiveEvery="Day"
archiveNumbering="Rolling" maxArchiveFiles-
s="10" archiveAboveSize="52428800" Keep-
FileOpen="false" ConcurrentWrites="true"/>
   </target>
   <target xsi:type="OutputDebugString" name-</pre>
e="String" layout="${longdate} ${log-
ger}::${message}"/>
   <target xsi:type="Debugger"</pre>
name="debugger" layout="${longdate} ${log-
ger}::${message}"/>
</targets>
```

Within this target, look for the reference to \${message} and modify the message structure to \${message}\${newline}\${microsoftconsolelayout} like so:

```
<targets>
   <target xsi:type="AsyncWrapper" name ="Lo-</pre>
ogfileAsync">
      <target xsi:type="File" name="logfile"
fileName="C:\Keyfactor\logs\Command_Claim-
sProxy_Log.txt" layout="${longdate}
${logger} [${level}] - ${mes-
sage}${newline}${microsoftconsolelayout}"
         archiveFileName-
e="c:\Keyfactor\logs\Command_ClaimsProxy_
Log_Archive_{#}.txt" archiveEvery="Day"
archiveNumbering="Rolling" maxArchiveFiles-
s="10" archiveAboveSize="52428800" Keep-
FileOpen="false" ConcurrentWrites="true"/>
   </target>
   <target xsi:type="OutputDebugString" name-</pre>
e="String" layout="${longdate} ${log-
ger}::${message}"/>
```

Configuration File	Description	
	<pre></pre>	

### 2.2.4.2 Audit Log Output to a Centralized Logging Solution

Keyfactor Command audit logging supports collecting audit entries in real time, as they are generated, to a separate server for analysis by a centralized logging solution. A variety of solutions can be supported. Typically the logs are either delivered to an rsyslog daemon on a Linux server, where they are consolidated with other logs and delivered on to a centralized solution, or delivered straight into the receiving pipeline of a centralized solution using a tool such as Splunk or Logstash. Delivery of the logs over a TLS connection is supported for backend solutions that support this option. Configuration of a centralized logging solution for delivery of the audit logs to a backend solution is beyond the scope of this guide. However, a sample rsyslog.conf file showing typical TLS configuration can be found in *Prepare for External Log Shipping over TLS (Optional)* in the *Keyfactor Command Server Installation Guide*.

The log output settings can be initially configured during installation and can be updated on the auditing tab of the applications settings page. The application settings that relate to log output are:

- Host Name
   Set this to the fully qualified domain name of the server that will be receiving the logs.
- Port
   Set this to the TCP port on which your log receipt application is listening to receive the logs. The default value is 514 (the default rsyslog port).
- Use SysLog Server
   This option defaults to False. Set it to True to enable delivery of logs to an outside server.
- Use TLS Connection
   This option defaults to False. Set it to True to enable delivery of logs to an outside server over TLS.

When you click **Save**, Keyfactor Command will verify that a connection can be made to the specified server on the specified port.

## 2.2.4.3 Keyfactor Command Windows Event IDs

Both Keyfactor Command and Keyfactor Orchestrators generate Windows event log messages for both normal activity and errors in the Windows application event log. <u>Table 86: Keyfactor Command Windows Event IDs</u> shows some of the more common event IDs generated by the Keyfactor Command server (source Certificate Management System or CMS Timer Job Servce). <u>Table 88: Keyfactor Universal Orchestrator Windows Event IDs</u> shows some of the more common event IDs generated by the Keyfactor Orchestrator (source Certificate Management System Agent). Depending on the features in use on your server, you may not see all these events in your log. These codes can be useful to set up log analysis platforms such as Splunk and Kibana.

Table 86: Keyfactor Command Windows Event IDs

Event ID	Task Category	Description
200	CA Synchron- ization	Incremental CA synchronization started
201	CA Synchron- ization	Incremental CA synchronization finished
210	CA Synchron- ization	An error occurred during CA synchronization
220	CA Synchron- ization	Unable to connect to the CA during incremental CA synchronization
221	CA Synchron- ization	Unable to validate Keyfactor Command product license
222	CA Synchron- ization	Unable to read the Keyfactor Command database during incremental CA synchronization
230	CA Synchron- ization	Unable to connect to the CA during full CA synchronization
300	Monitoring	Monitoring service started
301	Monitoring	Monitoring engine started
304	Monitoring	Monitoring service timer elapsed
305	Monitoring	Monitoring service execution skipped
306	Monitoring	Monitoring job completed successfully
307	Monitoring	Monitoring engine failed
310	Monitoring	Monitoring job completed with errors

Event ID	Task Category	Description
322	Monitoring	Unable to read the Keyfactor Command database during monitor job run
323	Monitoring	An error occurred refreshing a key rotation, cert expiration, CA Health, cert issued, pending cert, or query item alert service job
330	Monitoring	OCSP endpoint is unavailable
331	Monitoring	OCSP endpoint is responding successfully
340	Monitoring	An error occurred configuring an expiration alert
350	Monitoring	An error occurred configuring a pending alert
360	Monitoring	An error occurred configuring an SSL alert
370	Monitoring	An error occurred configuring the CRL
371	Monitoring	CRL endpoint location could not be contacted
372	Monitoring	CRL at the endpoint is stale (past the CA's next publish date for the CRL but not yet at the expiration date)  Note: If a CRL is both in the warning period and stale, only the event log message for stale will appear in the log.
373	Monitoring	CRL at the endpoint is in the warning period configured for email alerts (X days before expiration)
374	Monitoring	CRL is in a good state
375	Monitoring	CRL at the endpoint has expired
380	Monitoring	An error occurred configuring a SSRS reporting job, CRL alert jobs, or certificate authority threshold jobs
390	Monitoring	Failed to configure the certificate authority threshold jobs
391	Monitoring	CA has failed to meet one of the threshold monitoring requirements
410	Web API	A general error occurred during a Keyfactor API request
411	Web API	Invalid token error occurred during a Keyfactor API request
413	Web API	Invalid template error occurred during a Keyfactor API request

Event ID	Task Category	Description
419	Web API	Invalid user error occurred during a Keyfactor API request
800	Timer Service	Keyfactor Command Service started
801	Timer Service	Keyfactor Command Service stopped
810	Maintenance	A general Keyfactor Command Service maintenance error occurred.
822	Timer Service	Unable to read the Keyfactor Command database during Keyfactor Command Service job
830	Timer Service	Keyfactor Command Service jobs failed to start (alerts, monitoring, sync, other)
930	Timer Service	An orchestrator job configuration failed
931	Timer Service	An orchestrator job execution failed
1001	Maintenance	Keyfactor Command product license is approaching expiration
1002	Maintenance	Audit logs failed to write to the audit log destination
1900	Configuration Wizard	The configuration wizard was started
1910	Configuration Wizard	The configuration wizard finished
1911	Configuration Wizard	The configuration wizard database creation process started
1912	Configuration Wizard	The configuration wizard database upgrade process started
1913	Configuration Wizard	The configuration wizard database conversion process started
1914	Configuration Wizard	The configuration wizard database upgrade process completed successfully
1915	Configuration Wizard	The configuration wizard database creation process completed successfully
1916	Configuration Wizard	The configuration wizard database conversion process completed successfully
1920	Configuration	A general failure occurred for the configuration wizard

Event ID	Task Category	Description
	Wizard	
1921	Configuration Wizard	The configuration wizard database upgrade process failed
1922	Configuration Wizard	The configuration wizard database creation process failed
1940	Configuration Wizard	Configuration wizard general warning
1941	Configuration Wizard	Configuration wizard SSRS reporting config warning
1942	Configuration Wizard	Configuration wizard agent pool config warning
2000	Alert	Whitelist policy failure
2300	Expiration Renewal	Renewal handler was able to successfully renew a certificate
2310	Expiration Renewal	Renewal handler failed to renew a certificate
2800	User Authentication	User login to Management Portal was authenticated
3000	Alert	Execution of an alert (pending, issued, expiration, or key rotation) configured in the Management Portal failed.
3001	Alert	Execution of an alert (pending, issued, expiration, or key rotation) configured in the Management Portal succeeded.
3002	Alert	Execution of an alert (pending, issued, expiration, or key rotation) configured in the Management Portal was canceled.
3003	Alert	Execution of an alert (pending, issued, expiration, or key rotation) configured in the Management Portal started.
3004	Alert	A CA threshold monitoring alert failed.
3005	Alert	A CA threshold monitoring alert succeeded.
3006	Alert	A CA threshold monitoring alert was canceled.
3007	Alert	A CA threshold monitoring alert started.
3008	Alert	A CRL alert for a revocation monitoring location configured in the

Event ID	Task Category	Description
		Management Portal failed.
3009	Alert	A CRL alert for a revocation monitoring location configured in the Management Portal succeeded.
3010	Alert	A CRL alert for a revocation monitoring location configured in the Management Portal was canceled.
3011	Alert	A CRL alert for a revocation monitoring location configured in the Management Portal started.
3012	Certificate Authority	Local CA sync failed.
3013	Certificate Authority	Local CA sync succeeded.
3014	Certificate Authority	Local CA sync was canceled.
3015	Certificate Authority	Local CA sync started.
3016	Other	Delivery of regularly scheduled reports has failed.
3017	Other	Delivery of regularly scheduled reports has succeeded.
3018	Other	Delivery of regularly scheduled reports has been canceled.
3019	Other	Delivery of regularly scheduled reports has started.
3020	Maintenance	The process to generate and assign metadata to certificates when they are imported into Keyfactor Command has started.
3021	Maintenance	The process to generate and assign metadata to certificates when they are imported into Keyfactor Command has failed.
3022	Maintenance	The process to generate and assign metadata to certificates when they are imported into Keyfactor Command has been canceled.
3023	Maintenance	The periodic process to generate and assign metadata to certificates when they are imported into Keyfactor Command has succeeded.
3024	Maintenance	The periodic process to remove any stored private keys in the Keyfactor Command database that have expired and are eligible for

Event ID	Task Category	Description
		deletion has started.
3025	Maintenance	The periodic process to remove any stored private keys in the Keyfactor Command database that have expired and are eligible for deletion has failed.
3026	Maintenance	The periodic process to remove any stored private keys in the Keyfactor Command database that have expired and are eligible for deletion has been canceled.
3027	Maintenance	The periodic process to remove any stored private keys in the Keyfactor Command database that have expired and are eligible for deletion has succeeded.
3028	Maintenance	The periodic process to add audit log entries for large jobs started.
3029	Maintenance	The periodic process to add audit log entries for large jobs failed.
3030	Maintenance	The periodic process to add audit log entries for large jobs was canceled.
3031	Maintenance	The periodic process to add audit log entries for large jobs succeeded.

# 2.2.5 License Expiration Monitoring and Rotation

As your license is approaching expiration, warnings will be written to the Windows event log on the server running the Keyfactor Command service 60 days, 30 days and 5 days in advance of the license expiration (or at the next start of the Keyfactor Command service that falls within these time periods) using event ID 1001.

Figure 417: License Expiration Event Log

New primary Keyfactor Command licenses may be updated on the Licenses page of the Keyfactor Command Management Portal (see Licensing on page 769).

**Tip:** An error message of "Denied by Policy Module" with "Class is not licensed for use 0x80040112" on an attempt to enroll against a CA running the Keyfactor CA Policy Module can be an indication that the license for the policy module has expired.

New licenses for the Keyfactor CA Policy Module should be installed on the CA where the policy module is installed as follows:

- 1. On the CA where the policy module is installed, open the Certification Authority management tool.
- 2. In the Certification Authority management tool, right-click the CA name at the top of the tree and choose **Properties**.
- 3. In the Properties dialog for the CA on the CA Policy Module tab, confirm that the *Keyfactor Custom Policy Module* is the selected module and click **Properties**.
- 4. On the Licensing tab of the Policy Module Configuration Properties page, click **Upload License** and browse to locate the license file provided to you by Keyfactor. This file should have the extension CMSLICENSE.

Figure 418: Upload a New Keyfactor Command License

- 5. Click **OK** as many times as needed to close the configuration dialogs and save the configuration.
- 6. Restart the CA services.

# 2.2.6 Disaster Recovery

Preparing for recovery of your Keyfactor Command server in the event of a disaster or in anticipation of a planned event such as a software upgrade or hardware migration involves backing up several different components. The bulk of the data for a Keyfactor Command server implementation is stored in a SQL database, so backing up this SQL database regularly is key. A portion of the data stored in this database is encrypted, so you will need the appropriate components to allow you to access this encrypted information.

Ideally, your disaster recovery plan would include backing up each server hosting a Keyfactor role as a whole entity. This greatly simplifies recovery. With a plan of this sort, you would need these backed up components:

· Keyfactor Servers

Each server hosting a Keyfactor role—your Keyfactor Command servers, any Keyfactor orchestrators, etc.—should be backed up as entire entities with the full OS and installed applications.

- Your Keyfactor Command SQL Database
  - All the Keyfactor Command data—both configuration data and synchronized data such as certificates—is contained within one database, which should be backed up regularly.
- The SQL server Database Master Key (DMK) and Service Master Key (SMK) for your SQL Database

If you need to restore your SQL database to a different SQL server instance than the one from which it was backed up, you will need either the DMK or the SMK. There are pros and cons to restoring with each of these, so it can be useful to have both available when you make the restore decision. These only need to be backed up once unless you change either of these in SQL. See SQL Encryption Key Backup on the next page.

If backing up each server as a whole entity is not feasible or you would like to also back up components on the servers that differ from a stock install, consider including the following items for backup:

· Your nlog.config Files

The various Keyfactor Command server components and most other Keyfactor products have an nlog.config file that sets the logging level for the product and the output path for the log files. If you have made any customizations to any of these configuration files, you may find it useful to make a backup of them. For Keyfactor Command server, the Nlog.config files for the various Keyfactor Command components are in application-specific subdirectories under the installation directory, which is by default:

C:\Program Files\Keyfactor\Keyfactor Platform

### For example:

- C:\Program Files\Keyfactor\Keyfactor Platform\WebConsole\NLog\_Portal.config
- C:\Program Files\Keyfactor\Keyfactor Platform\KeyfactorAPI\NLog\_KeyfactorAPI.config
- Customizations for PAM Configuration

If you have implemented a PAM solution and manually made configuration changes for this (see <a href="Installing Custom PAM Provider Extensions on page 745">Installing Custom PAM Provider Extensions on page 745</a>), you may want to include these files in a one-time backup.

· Event Handler Scripts

If you have implemented any event handler scripts for alerting (see <u>Using Event Handlers on page 218</u>), you may want to backup these files.

· PowerShell Scripts for Workflow

If you have implemented any custom PowerShell steps for that use external scripts (see Workflow Definitions on page 230), you may want to backup these files.

Any Other Text-Based Files

If you have modified any other text-based configuration files on your Keyfactor Command server (this is uncommon), you will want to have a one-time backup of these.

The process of restoring from backup depends on the components that have been affected. If only the Keyfactor Command server has been lost but the database is intact, the server may be restored

from backup and re-connected to the existing database. If a whole server backup does not exist, a fresh server may be installed, Keyfactor Command installed again and connected to the existing database, and any customized files restored or recreated. If the SQL database is lost, the database must be restored from backup along with either the DMK or SMK (see SQL Encryption Key Backup below).

For assistance with disaster recovery planning or implementation, please contact Keyfactor support (support@keyfactor.com).

### 2.2.6.1 SQL Encryption Key Backup

Keyfactor Command uses Microsoft SQL Server Encryption to encrypt portions of the database to protect secret data, including service account credentials. Understanding Keyfactor Command's use of SQL Server Encryption is important to a successful disaster recovery strategy.

SQL Server Encryption uses a SQL Server instance-level service master key (SMK) and a data-base-level database master key (DMK) to provide the top-level encryption hierarchy used when encrypting SQL data. The DMK is protected by one or more passwords and optionally the SMK. For an application—such as Keyfactor Command—to access SQL encrypted data, the application must either provide one of the DMK passwords or ask SQL Server to access the data via the SMK. Keyfactor Command uses the SMK. For more details on the mechanics of SQL Server Encryption and related disaster recovery procedures, see the SQL Server documentation.

When the Keyfactor Command database is created, the DMK is configured to be protected by the SMK and then the DMK password is set to a random value, which is not retained. This means the only way to get to the encrypted data is by leveraging the SMK, which happens automatically without any user interaction or the need to store the DMK password in a potentially insecure location.

Different restoration scenarios may require a backup of the SMK or the DMK or neither. Some restoration possibilities include:

- In the case where a Keyfactor Command database needs to be restored to the same SQL server where the backup was taken and the SQL Server software itself is not being restored, the correct SMK will still be present on the SQL server and restoration of the database itself is sufficient to be able to access the encrypted data.
- In the case where a Keyfactor Command database is being restored to a SQL Server with a different SMK (either a different SQL Server or the same SQL server that has been reinstalled or had its SMK changed), the encrypted data will be inaccessible because the server level SMK is not the same as it was when the DMK was created. In this scenario, either the DMK needs to be restored from the backup taken when the Keyfactor Command database was created or a known DMK password may be used to recover encrypted data within the Keyfactor Command database. To prepare for this scenario, the configuration wizard strongly encourages making a DMK backup when the Keyfactor Command database is created.
- In the case where a Keyfactor Command database needs to be restored to a SQL Server with a
  different SMK, the DMK cannot be restored and a DMK password is not known, a backup of the
  SMK may be used to restore the server, but this will affect any other databases on the server
  that make use of SQL encryption.

If no backup of the SMK or DMK exists, all DMK passwords are unknown, and the SQL server holding the SMK is lost, the encrypted data within Keyfactor Command is not recoverable (even with a database backup.)

To backup the DMK, as a user with *control* permission on the SQL server where the Keyfactor Command database is **select your Keyfactor Command database** and run the following SQL command:

```
BACKUP MASTER KEY TO FILE = 'path_to_file'
ENCRYPTION BY PASSWORD = 'SecurePassword#1234'
```

Replace "path\_to\_file" with a path and filename for the output file. This can be either a local path on the SQL server or a UNC path. The selected output directory must be writable by the service account under which SQL Server is running. By default, the SQL backup directory has appropriate permissions. Replace "SecurePassword#1234" with a secure password to protect the file. Store the backup file and the password in a safe, well-documented location. For more information, see:

https://docs.microsoft.com/en-us/sql/relational-databases/security/encryption/back-up-a-database-master-key?view=sql-server-ver15
https://docs.microsoft.com/en-us/sql/t-sql/statements/backup-master-key-transact-sql?view-w=sql-server-2017

To backup the SMK, as a user with *control server* permission run the following SQL command on the SQL server where the Keyfactor Command database is:

```
BACKUP SERVICE MASTER KEY TO FILE = 'path_to_file' ENCRYPTION BY PASSWORD = 'SecurePassword#1234'
```

Replace path\_to\_file with a path and filename for the output file. This can be either a local path on the SQL server or a UNC path. The selected output directory must be writable by the service account under which SQL Server is running. By default, the SQL backup directory has appropriate permissions. Replace SecurePassword#1234 with a secure password to protect the file. Store the backup file and the password in a safe, well-documented location. For more information, see:

https://docs.microsoft.com/en-us/sql/relational-databases/security/encryption/back-up-the-service-master-key?view=sql-server-ver15
https://docs.microsoft.com/en-us/sql/t-sql/statements/backup-service-master-key-transact-sql?view=sql-server-2017

To prepare for disaster recovery, you should have the DMK backup created during installation, an SMK backup, the passwords for these files and a recent database backup. You will likely only need either the DMK or the SMK if you need to restore to a SQL server instance other than the original SQL server instance, but it can be useful to have the flexibility to choose between the two at restoration time. If you need to restore to the original SQL server instance, you will only need a recent database backup and not either of the database keys. For information about restoring using the DMK or SMK, see <u>Disaster Recovery on page 818</u>.

# 2.2.7 SQL Database Migration

If you need to move your Keyfactor Command database from one SQL server to another, the process is similar to a controlled disaster recovery. You will need a backup of your Keyfactor Command database and the ability to decrypt the encrypted content within the database (see <a href="SQL Encryption Key Backup on page 820">SQL Encryption Key Backup on page 820</a>). By default, a new SQL server will have a different service master key (SMK) than your original SQL server. To support the migration, you have a few options:

- Set the SMK on the new server to match that of the old server and do a simple restore of the database. This may not be a feasible solution if there are any other applications on the new server that use SQL encryption.
- Temporarily add a known password to the database master key (DMK) on the Keyfactor Command database (if one is not known already).

To transfer a Keyfactor Command database between two SQL servers that do not share the same SMK, as a user with *control* permission on the Keyfactor Command database:

1. Add a known password to the DMK by issuing the following SQL command in the Keyfactor Command database. You can specify any password you want that meets the Windows password complexity rules.

ALTER MASTER KEY ADD ENCRYPTION BY PASSWORD = 'SecurePassword#1234'

**Important:** Note that at this point, in addition to the backup you are about to manually make, any automated backups of the Keyfactor Command database will contain this DMK password and anyone with access to the backup media and the password would be able to decrypt the sensitive information within the Keyfactor Command database.

- 2. Use your preferred SQL server tools to back up the database, copy the backup media to the target server, and restore the database on the target server.
- 3. Use the following SQL commands on the target server to manually open the DMK, protect the DMK with the target server's SMK, and remove the DMK password (referencing the password you used on your DMK):

OPEN MASTER KEY DECRYPTION BY PASSWORD = 'SecurePassword#1234'

ALTER MASTER KEY ADD ENCRYPTION BY SERVICE MASTER KEY

ALTER MASTER KEY DROP ENCRYPTION BY PASSWORD = 'SecurePassword#1234'

4. Open a new query window on the target server and use the following SQL to validate that the DMK is properly encrypted by the SMK and that the Keyfactor Command application will be able to ask SQL server to decrypt information in the database. The commands should run without error. OPEN SYMMETRIC KEY [CMS\_SecretsSymmetricKey] DECRYPTION BY CERTIFICATE [CMS\_SecretsCertificate];

CLOSE SYMMETRIC KEY [CMS\_SecretsSymmetricKey]

5. On the source server, if you are not going to remove the Keyfactor Command database, issue the following SQL command to remove the DMK that was added (referencing the password you used on your DMK):

ALTER MASTER KEY DROP ENCRYPTION BY PASSWORD = 'SecurePassword#1234'

Delete the backup or securely store the backup media that was used, along with the temporary DMK password, as it can be used to obtain the encrypted Keyfactor Command information.

### 2.2.8 Troubleshooting

The following error conditions and general troubleshooting tips may be helpful in resolving issues with the Keyfactor Command server. Generally speaking, issues on installation or upgrade are often related to SQL connectivity or permissions. When Active Directory is used as the identity provider, certificate enrollment issues are often related to Kerberos configuration problems.

# **IIS Authentication Configuration**

If authentication is not working as expected, it can be helpful to review whether the authentication configuration in IIS is correct for the identity provider you have configured. The correct IIS authentication configurations are:

• If you're using Keyfactor Identity Provider, the *KeyfactorAgents*, *KeyfactorAPI*, and *KeyfactorPortal* virtual directories should be set with Anonymous Authentication enabled and all other authentication methods disabled.

Figure 419: IIS Authentication for Virtual Directories with Keyfactor Identity Provider

• If you're using Active Directory, the default configuration for the KeyfactorAgents, KeyfactorAPI, and KeyfactorPortal virtual directories is Anonymous Authentication, Basic Authentication, and Windows Authentication enabled. You have the option to disable either Basic Authentication or Windows Authentication for the KeyfactorPortal and KeyfactorAPI virtual directories to force users to login with only one of these methods, if desired. The KeyfactorAgents virtual directory may be configured to Anonymous Authentication only if certificate-based authentication is in use for your orchestrators (see Appendices in the Keyfactor Orchestrators Installation and Configuration Guide).

Figure 420: IIS Authentication for Virtual Directories with Active Directory

**Note:** If you make customizations to the authentication settings such as disabling Basic Authentication for the KeyfactorPortal virtual directory and subsequently enable the OAuth option in the configuration wizard, these customizations will be lost.

- The KeyfactorAnalysis and KeyfactorProxy virtual directories are set with only Anonymous Authentication for all identity provider configurations.
- At the site level (e.g. Default Web Site), only Anonymous Authentication should be enabled for all identity provider configurations.

### **Debug Logging and Error Messages**

It is often helpful to enable debug logging on the server. For information on configuring this, see Editing NLog on page 796.

Once the logging is set at debug or trace level, it can be helpful to watch the logs live while activity is going on. There are tools on Windows with functionality similar to the Linux tail function to watch the log in real time. Notepad++, for example, has this functionality built in. Be sure to review all the logs that could be relevant. For example, installation and configuration messages are found in the configuration log. Messages related to using the Management Portal can be found in both the portal log and the Keyfactor API log.

Some messages in the Keyfactor API and orchestrators API logs include a correlation ID that helps to identify log messages that originated from the same request. The correlation ID is a randomly generated GUID that often appears just after the date in the log entry (C282ACA1-DED5-4F2E-B83B-F3F9E865E371 in the following example) and is the same for all log messages for the given request until the request completes.

```
2022-09-13 04:51:18.6884 C282ACA1-DED5-4F2E-B83B-F3F9E865E371 CSS.CMS.We-b.KeyfactorApi.Controllers.Enrollment.Enrollment2Controller [Trace] - Starting PFX Enrollment Process 2022-09-13 04:51:19.0477 C282ACA1-DED5-4F2E-B83B-F3F9E865E371 Keyfactor.Command.Workflows.Engine.WorkflowGraph [Error] - Invalid O provided: Value must be Key Example, Inc or Key Example.
```

### **General Errors**

Below are some possible errors you might encountered and some suggested troubleshooting tips or solutions.

A connection was successfully established with the server, but then an error occurred during the login process. (provider: SSL Provider, error: 0 - The certificate chain was issued by an authority that is not trusted.)

You many encounter this error when trying to install or upgrade to Keyfactor Command version 10 or later:

```
2022-03-04 09:58:55.7262 CSS.CMS.Install.ConfigurationWizard.ViewModels.DatabaseViewModel [Error] - Unable to configure database 2022-03-04 09:58:55.9821 CSS.CMS.Install.ConfigurationWizard.ViewModels.DatabaseViewModel [Error] - An error occurred while preparing the database at CSS.CMS.Install.ConfigurationWizard.ViewModels.DatabaseViewModel.b(Object A_0, RunWork-erCompletedEventArgs A_1)

A connection was successfully established with the server, but then an error occurred during the login process. (provider: SSL Provider, error: 0 - The certificate chain was issued by an authority that is not trusted
```

Keyfactor Command version 10 requires an encrypted connection to the SQL server. If the SQL server is not configured correctly to receive a secure connection (is not configured with a valid certificate that is trusted by the Keyfactor Command server), you may receive this message.

For information about configuring TLS for SQL server, see:

https://docs.microsoft.com/en-us/sql/database-engine/configure-windows/enable-encrypted-connections-to-the-database-engine?view=sql-server-ver15

The request subject name is invalid or too long

The certificate request failed with the reason 'The request subject name is invalid or too long. (Exception from HRESULT: 0x80094001).'

You may encounter this error on an enrollment when the CA rejects the request. If the request is clearly not excessively long, review the request for invalid characters. Be sure to also check the default subject (see the Subject Format application setting on the Application Settings: Enrollment Tab on page 610 and the subject defaults in certificate templates for both Configuring System—Wide Settings on page 383 and Enrollment Defaults Tab on page 399). Quotation marks should not be used in the fields of the default subject except in the case where these are part of the desired subject value, as they are processed as literal values. This is a change from earlier versions of Keyfactor Command where quotation marks were used around fields containing embedded commas.

This error can also appear if a Microsoft CA receives an enrollment request with no subject at all.

### An error occurred while reading the key ring

You may encounter this error in the Keyfactor Command logs when trying to connect to the Management Portal. This can indicate that one or more of the service accounts configured to run the IIS application pools for Keyfactor Command do not have private key permissions to the certificate used to provide application-level encryption in Keyfactor Command (see Application-Level Encryption and Install the Keyfactor Command Components on the Keyfactor Command Server(s): Database Tab in the Keyfactor Command Server Installation Guide). To resolve this, grant private key read permissions on that certificate to each application pool user.

```
Category: Microsoft.AspNetCore.DataProtection.KeyManagement.KeyRingProvider
EventId: 48

An error occurred while reading the key ring.

Exception:

System.Exception: Unable to decrypt enveloped PKCS7 data
```

### Request failed with status code 405

You may encounter this error either in the Keyfactor CommandManagement Portal or when submitting a Keyfactor API request. This error is typically not accompanied by any error in the Keyfactor Command logs. This error can occur if the IIS WebDAV Publishing feature is installed on the Keyfactor Command server. Keyfactor Command is not compatible with this IIS feature. Uninstall the WebDAV Publishing feature, reboot if required, and try your command again.

### Denied by Policy Module: Class is not licensed for use 0x80040112

This error may appear during certificate enrollment against a certificate authority running the Keyfactor CA Policy Module if the license for the policy module has expired. See <u>License Expiration Monitoring and Rotation on page 817 for license update information.</u>

### Incorrect property 'value' for basic certificate extension

You may encounter an error similar to the following in the EJBCA log (not one of the Keyfactor Command logs) on a certificate enrollment if you make an enrollment attempt through Keyfactor Command using an EJBCA certificate profile configured with one or more custom certificate extensions that do not have a matching enrollment field configuration in Keyfactor Command. This may occur when using templates intended for use with the Keyfactor Windows Enrollment Gateway with incomplete Keyfactor Command configuration.

```
2023-07-05 19:43:45,248 ERROR
[org.cesecore.certificates.certificate.CertificateCreateSessionBean] (default task-19)
Error creating certificate:
org.cesecore.certificates.certificate.certextensions.CertificateExtensionException:
```

Incorrect property 'value' for basic certificate extension with id : 0 and OID : 1.3.6.1.4.1.311.21.7

Figure 421: EJBCA Certificate Profile Custom Certificate Extensions

To operate correctly with Keyfactor Command, the profiles in EJBCA will need to be configured to not expect extension data. If you're using the the Keyfactor Windows Enrollment Gateway and wish to do direct enrollments in Keyfactor Command for your EJBCA CA as well as through the Keyfactor Windows Enrollment Gateway, you will need a separate set of certificate profiles in EJBCA that are not configured to expect extension data with the request to use for direct enrollment from Keyfactor Command.

### Web Server Errors When Authenticating with Keyfactor Identity Provider

If you encounter a web server error (e.g. a 502 error) while authenticating with Keyfactor Identity Provider or across the entire Keyfactor Command product once you have authenticated with Keyfactor Identity Provider, it can be helpful to enable extended logging for the ClaimsProxy log. For more information, see Table 85: NLog.config Files for Keyfactor Command.

### **Certificate Validation Errors**

On the Validation tab of the certificate details you will sometimes see a fail result for some of the validation tests. The following are some possible reasons why this might occur.

- If you see both *Full Chain* and *CRL Online* in a fail state, this generally indicates that you have not imported the root and/or intermediate certificate for the certificate into the appropriate store on the Keyfactor Command server (see *Configure Certificate Chain Trusts for CAs* in the *Keyfactor Command Server Installation Guide*).
- If you see just *CRL Online* in a fail state, this generally indicates that the Certificate Revocation List (CRL) for the CA could not be reached.

**Important:** Because a "+" (plus sign) in a URL can represent either a space or a "+" Keyfactor Command has chosen to read "+" as a space. For CRL URLs that require a "+" (plus sign), rather than a space, replace plus signs in your CRL's URL with "%2B". Only replace the plus signs you don't wish to be treated as a space.

• If you see *Revocation Status* in a fail state but *CRL Online* is in a pass state, this can indicate that the CRL is accessible but expired, that the CRL is not fully configured, or that the Authority

Information Access (AIA) for the CA has not been configured correctly or could not be reached. For EJBCA CAs, CRLs and AIA need to be configured both at the CA level and at the certificate profile level. One way to do this is:

- AIA: Set the path to the AIA in the CA issuer Default URI field in the CA. You can find this on the Fetch CA certificates page of your EJBCA public web. Check both the Authority Information Access box and the Use CA defined CA issuer box in each certificate profile.
- ORL: Set the path to the CRL distribution point (CDP) in the Default CRL Distribution Point field in the CA. If appropriate for your environment, set also the Default CRL Issuer and/or Default Freshest CRL Distribution Point (delta CRLs). Check both the CRL Distribution Points box and the Use CA defined CRL Distribution Point box in each certificate profile.

Figure 422: Certificate Validation Fails for Full Chain and CRL Online

### Slow SSL Jobs

If SSL jobs are taking longer to complete than expected and you check the log on the orchestrator and find messages similar to the following:

2021-08-24 17:22:48.4463 Keyfactor.WindowsAgent.Jobs.SSL.SslDiscovery [Error] - Error while sending SSL Batch for audit id 158558. Check the CMS Server log for more details. Response status code does not indicate success: 413 (Request Entity Too Large). at System.Net.Http.HttpResponseMessage.EnsureSuccessStatusCode() at Keyfactor.WindowsAgent.Jobs.GenericJobExecutor`7.f.h()

2021-08-24 17:22:48.4463 Keyfactor.WindowsAgent.Jobs.SSL.SslDiscovery [Info] - Splitting endpoint result batch of 29 into smaller pieces and retrying

You may want to make modifications to the IIS maximum request size settings on your Keyfactor Command server to allow it to accept larger incoming pieces of content to streamline SSL scanning. You can do this using the configuration editor built into the IIS management console. Make the setting changes at the Default Web Site level (or other web site, if you installed your Keyfactor Command in an alternate web site). There are three settings to change:

- system.webServer/security/requestFiltering/requestLimits/maxAllowedContentLength
- system.webServer/serverRuntime/uploadReadAheadSize
- system.web/httpRuntime/maxRequestLength

Set each system.webServer value to at least 1,000,000 bytes for best SSL scanning performance. The default value of 4096 KB for the maxRequestLength will probably be sufficient for SSL scanning in most environments, but if it has been reduced in your environment, you may need to increase it. (The system.webServer values are set in bytes while the system.web values are set in kilobytes.) If you are scanning networks with especially large numbers of returned certificates, you may need to increase all these values. Monitor the orchestrator logs after modifying the values to confirm that you have achieved the desired effect.

Figure 423: Modify IIS Settings for SSL Scanning: maxAllowedContentLength

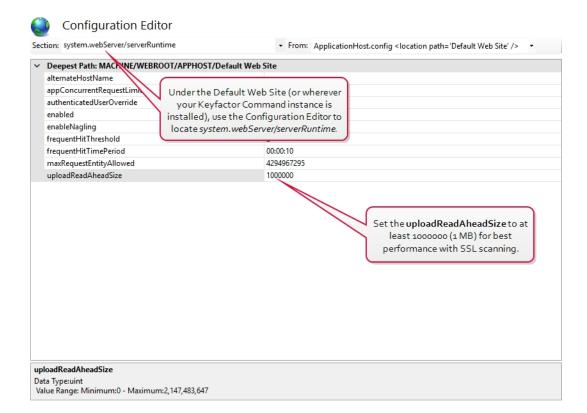

Figure 424: Modify IIS Settings for SSL Scanning:uploadReadAheadSize

Figure 425: Modify IIS Settings for SSL Scanning: maxRequestLength

### 2.2.8.1 Disable Loopback Checking

For some features of the Management Portal to function correctly when using Kerberos authentication (e.g. delegation of CA functions, alerting using the event logging event handler and a DNS alias or alternate target machine), it may be necessary to disable loopback checking on the Keyfactor Command server.

To disable loopback checking for selected FQDNs:

1. On the Keyfactor Command server, open the registry editor and browse to:

HKEY\_LOCAL\_MACHINE\SYSTEM\Cur-rentControlSet\Services\LanmanServer\Parameters

Right-click the Parameters registry key and choose New > DWORD (32-bit) Value. Name the
new DWORD value DisableStrictNameChecking. Set the DisableStrictNameChecking value to
1.

Figure 426: Disable Loopback Checking: DisableStrictNameChecking

3. In the registry editor browse to:

HKEY\_LOCAL\_MACHINE\SYSTEM\CurrentControlSet\Control\Lsa\MSV1\_0

4. Right-click the MSV1\_0 registry key and choose New > Multi-String Value. Name the new value BackConnectionHostNames. Edit the BackConnectionHostNames value and enter each fully qualified domain name—actual name or DNS alias—for a server that needs this feature on a separate line. For example, for full DNS alias support with CA delegation functions, you need to enter the DNS alias of the Keyfactor Command server. For event logging to a machine other than the Keyfactor Command server, you need to enter the name of that server.

Figure 427: Disable Loopback Checking: BackConnectionHostNames

5. After completing the registry configuration you must reboot the Keyfactor Command server before the changes will take effect.

### 2.3.2.1 Apache 2.0 License Text:

Version 2.0, January 2004

http://www.apache.org/licenses/

TERMS AND CONDITIONS FOR USE, REPRODUCTION, AND DISTRIBUTION

#### 1. Definitions.

"License" shall mean the terms and conditions for use, reproduction, and distribution as defined by Sections 1 through 9 of this document.

"Licensor" shall mean the copyright owner or entity authorized by the copyright owner that is granting the License.

"Legal Entity" shall mean the union of the acting entity and all other entities that control, are controlled by, or are under common control with that entity. For the purposes of this definition, "control" means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

"You" (or "Your") shall mean an individual or Legal Entity exercising permissions granted by this License.

"Source" form shall mean the preferred form for making modifications, including but not limited to software source code, documentation source, and configuration files.

"Object" form shall mean any form resulting from mechanical transformation or translation of a Source form, including but not limited to compiled object code, generated documentation, and conversions to other media types.

"Work" shall mean the work of authorship, whether in Source or Object form, made available under the License, as indicated by a copyright notice that is included in or attached to the work (an example is provided in the Appendix below).

"Derivative Works" shall mean any work, whether in Source or Object form, that is based on (or derived from) the Work and for which the editorial revisions, annotations, elaborations, or other modifications represent, as a whole, an original work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.

"Contribution" shall mean any work of authorship, including the original version of the Work and any modifications or additions to that Work or Derivative Works thereof, that is intentionally submitted to Licensor for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to submit on behalf of the copyright owner. For the purposes of this definition, "submitted" means any form of electronic, verbal, or written communication sent to the Licensor or its representatives, including but not limited to communication on electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as "Not a Contribution."

"Contributor" shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.

### 2. Grant of Copyright License.

Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.

### 3. Grant of Patent License.

Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes direct or contributory patent infringement, then any patent licenses granted to You under this License for that Work shall terminate as of the date such litigation is filed.

### 4. Redistribution.

You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:

You must give any other recipients of the Work or Derivative Works a copy of this License; and

You must cause any modified files to carry prominent notices stating that You changed the files; and

You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and

If the Work includes a "NOTICE" text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and do not modify the License. You may add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.

#### Submission of Contributions.

Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement you may have executed with Licensor regarding such Contributions.

### 6. Trademarks.

This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.

### 7. Disclaimer of Warranty.

Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions) on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.

### 8. Limitation of Liability.

In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work

stoppage, computer failure or malfunction, or any and all other commercial damages or losses), even if such Contributor has been advised of the possibility of such damages.

9. Accepting Warranty or Additional Liability.

While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with this License. However, in accepting such obligations, You may act only on Your own behalf and on Your sole responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor by reason of your accepting any such warranty or additional liability.

#### 2.3.2.2 BSD License Text:

Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met:

- 1. Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer.
- 2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.
- 3. Neither the name of the copyright holder nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission.

THIS SOFTWARE IS PROVIDED BY THE COPYRIGHT HOLDERS AND CONTRIBUTORS "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE COPYRIGHT HOLDER OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

### 2.3.2.3 MIT License Text:

Permission is hereby granted, free of charge, to any person obtaining a copy of this software and associated documentation files (the "Software"), to deal in the Software without restriction, including without limitation the rights to use, copy, modify, merge, publish, distribute, sublicense, and/or sell copies of the Software, and to permit persons to whom the Software is furnished to do so, subject to the following conditions:

The above copyright notice and this permission notice shall be included in all copies or substantial portions of the Software.

THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT. IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT HOLDERS BE LIABLE FOR ANY CLAIM, DAMAGES OR OTHER LIABILITY, WHETHER IN AN ACTION OF CONTRACT, TORT OR OTHERWISE, ARISING FROM, OUT OF OR IN CONNECTION WITH THE SOFTWARE OR THE USE OR OTHER DEALINGS IN THE SOFTWARE.

### 2.3.2.4 Microsoft Public License (MS-PL) Text:

This license governs use of the accompanying software. If you use the software, you accept this license. If you do not accept the license, do not use the software.

#### 1. Definitions

The terms "reproduce," "reproduction," "derivative works," and "distribution" have the same meaning here as under U.S. copyright law.

A "contribution" is the original software, or any additions or changes to the software.

A "contributor" is any person that distributes its contribution under this license.

"Licensed patents" are a contributor's patent claims that read directly on its contribution.

### 2. Grant of Rights

- (A) Copyright Grant- Subject to the terms of this license, including the license conditions and limitations in section 3, each contributor grants you a non-exclusive, worldwide, royalty-free copyright license to reproduce its contribution, prepare derivative works of its contribution, and distribute its contribution or any derivative works that you create.
- (B) Patent Grant- Subject to the terms of this license, including the license conditions and limitations in section 3, each contributor grants you a non-exclusive, worldwide, royalty-free license under its licensed patents to make, have made, use, sell, offer for sale, import, and/or otherwise dispose of its contribution in the software or derivative works of the contribution in the software.

#### 3. Conditions and Limitations

- (A) No Trademark License- This license does not grant you rights to use any contributors' name, logo, or trademarks.
- (B) If you bring a patent claim against any contributor over patents that you claim are infringed by the software, your patent license from such contributor to the software ends automatically.
- (C) If you distribute any portion of the software, you must retain all copyright, patent, trademark, and attribution notices that are present in the software.
- (D) If you distribute any portion of the software in source code form, you may do so only under this license by including a complete copy of this license with your distribution. If you distribute any portion of the software in compiled or object code form, you may only do so under a license that complies with this license.

(E) The software is licensed "as-is." You bear the risk of using it. The contributors give no express warranties, guarantees or conditions. You may have additional consumer rights under your local laws which this license cannot change. To the extent permitted under your local laws, the contributors exclude the implied warranties of merchantability, fitness for a particular purpose and non-infringement.

### 2.3.2.5 Microsoft Reciprocal License (MS-RL) Text:

This license governs use of the accompanying software. If you use the software, you accept this license. If you do not accept the license, do not use the software.

#### 1. Definitions

The terms "reproduce," "reproduction," "derivative works," and "distribution" have the same meaning here as under U.S. copyright law.

A "contribution" is the original software, or any additions or changes to the software.

A "contributor" is any person that distributes its contribution under this license.

"Licensed patents" are a contributor's patent claims that read directly on its contribution.

### 2. Grant of Rights

- (A) Copyright Grant- Subject to the terms of this license, including the license conditions and limitations in section 3, each contributor grants you a non-exclusive, worldwide, royalty-free copyright license to reproduce its contribution, prepare derivative works of its contribution, and distribute its contribution or any derivative works that you create.
- (B) Patent Grant- Subject to the terms of this license, including the license conditions and limitations in section 3, each contributor grants you a non-exclusive, worldwide, royalty-free license under its licensed patents to make, have made, use, sell, offer for sale, import, and/or otherwise dispose of its contribution in the software or derivative works of the contribution in the software.

### 3. Conditions and Limitations

- (A) Reciprocal Grants- For any file you distribute that contains code from the software (in source code or binary format), you must provide recipients the source code to that file along with a copy of this license, which license will govern that file. You may license other files that are entirely your own work and do not contain code from the software under any terms you choose.
- (B) No Trademark License- This license does not grant you rights to use any contributors' name, logo, or trademarks.
- (C) If you bring a patent claim against any contributor over patents that you claim are infringed by the software, your patent license from such contributor to the software ends automatically.
- (D) If you distribute any portion of the software, you must retain all copyright, patent, trademark, and attribution notices that are present in the software.

- (E) If you distribute any portion of the software in source code form, you may do so only under this license by including a complete copy of this license with your distribution. If you distribute any portion of the software in compiled or object code form, you may only do so under a license that complies with this license.
- (F) The software is licensed "as-is." You bear the risk of using it. The contributors give no express warranties, guarantees or conditions. You may have additional consumer rights under your local laws which this license cannot change. To the extent permitted under your local laws, the contributors exclude the implied warranties of merchantability, fitness for a particular purpose and non-infringement.

# 3.0 Glossary

#### Α

#### AIA

The authority information access (AIA) is included in a certificate--if configured--and identifies a location from which the chain certificates for that certificate may be retrieved.

### **AnyAgent**

The AnyAgent, one of Keyfactor's suite of orchestrators, is used to allow management of certificates regardless of source or location by allowing customers to implement custom agent functionality via an API.

### **AnyGateway**

The Keyfactor AnyGateway is a generic third party CA gateway framework that allows existing CA gateways and custom CA connections to share the same overall product framework.

### **API**

A set of functions to allow creation of applications. Keyfactor offers the Keyfactor API, which allows third-party software to integrate with the advanced certificate enrollment and management features of Keyfactor Command.

### **Argument**

A parameter or argument is a value that is passed into a function in an application.

#### **Authority Information Access**

The authority information access (AIA) is included in a certificate—if configured—and identifies a location from which the chain certificates for that certificate may be retrieved.

#### В

#### **Bash Orchestrator**

The Bash Orchestrator, one of Keyfactor's suite of orchestrators, is used to discover and manage SSH keys across an enterprise.

### **Blueprint**

A snapshot of the certificate stores and scheduled jobs on one orchestrator, which can be used to create matching certificate stores and jobs on another orchestrator with just a few clicks.

#### C

### CA

A certificate authority (CA) is an entity that issues digital certificates. Within Keyfactor Command, a CA may be a Microsoft CA or a Keyfactor gateway to a cloud-based or remote CA.

#### **Certificate Authority**

A certificate authority (CA) is an entity that issues digital certificates. Within Keyfactor Command, a CA may be a Microsoft CA or a Keyfactor gateway to a cloud-based or remote CA.

### **Certificate Revocation List**

A Certificate Revocation List (CRL) is a list of digital certificates that have been revoked by the issuing Certificate Authority (CA) before their scheduled expiration date and should no longer be trusted.

#### **Certificate Signing Request**

A CSR or certificate signing request is a block of encoded text that is submitted to a CA when enrolling for a certificate. When you generate a CSR within Keyfactor Command, the matching private key for it is stored in Keyfactor Command in encrypted format and will be married with the certificate once returned from the CA.

#### CN

A common name (CN) is the component of a distinguished name (DN) that represents the primary name of the object. The value varies depending on the type of object. For a user object, this would be the user's name (e.g. CN=John Smith). For SSL certificates, the CN is typically the fully qualified domain name (FQDN) of the host where the SSL certificate will reside (e.g. servername.keyexample.com or www.keyexample.com).

#### Collection

The certificate search function allows you to query the Keyfactor Command database for certificates from any available source based on any criteria of the certificates and save the results as a collection that will be availble in other places in the Management Portal (e.g. expiration alerts and certain reports).

### **Common Name**

A common name (CN) is the component of a distinguished name (DN) that represents the primary name of the object. The value varies depending on the type of object. For a user object, this would be the user's name (e.g. CN=John Smith). For SSL certificates, the CN is typically the fully qualified domain name (FQDN) of the host where the SSL certificate will reside (e.g. servername.keyexample.com or www.keyexample.com).

### **Configuration Tenant**

A grouping of CAs. The Microsoft concept of forests is not used in EJBCA so to

accommodate the new EJBCA functionality, and to avoid confusion, the term forest needed to be renamed. The new name is configuration tenant. For EJBCA, there would be one configuration tenant per EJBCA server install. For Microsoft, there would be one per forest. Note that configuration tenants cannot be mixed, so Microsoft and EJBCA cannot exist on the same configuration tenant.

### **CRL**

A Certificate Revocation List (CRL) is a list of digital certificates that have been revoked by the issuing Certificate Authority (CA) before their scheduled expiration date and should no longer be trusted.

#### **CSR**

A CSR or certificate signing request is a block of encoded text that is submitted to a CA when enrolling for a certificate. When you generate a CSR within Keyfactor Command, the matching private key for it is stored in Keyfactor Command in encrypted format and will be married with the certificate once returned from the CA.

#### D

### DER

A DER format certificate file is a DERencoded binary certificate. It contains a single certificate and does not support storage of private keys. It sometimes has an extension of .der but is often seen with .cer or .crt.

### **Distinguished Name**

A distinguished name (DN) is the name that uniquely identifies an object in a directory. In the context of Keyfactor Command, this directory is generally Active Directory. A DN is made up of attribute=value pairs,

separated by commas. Any of the attributes defined in the directory schema can be used to make up a DN.

### DN

A distinguished name (DN) is the name that uniquely identifies an object in a directory. In the context of Keyfactor Command, this directory is generally Active Directory. A DN is made up of attribute=value pairs, separated by commas. Any of the attributes defined in the directory schema can be used to make up a DN.

### **DNS**

The Domain Name System is a service that translates names into IP addresses.

#### Ē

#### **ECC**

Elliptical curve cryptography (ECC) is a public key encryption technique based on elliptic curve theory that can be used to create faster, smaller, and more efficient cryptographic keys. ECC generates keys through the properties of the elliptic curve equation instead of the traditional method of generation as the product of very large prime numbers.

### **Endpoint**

An endpoint is a URL that enables the API to gain access to resources on a server.

### **Enrollment**

Certificate enrollment refers to the process by which a user requests a digital certificate. The user must submit the request to a certificate authority (CA).

### **EOBO**

A user with an enrollment agent certificate can enroll for a certificate on behalf of another user. This is often used when provisioning technology such as smart cards.

#### F

#### **Forest**

An Active Directory forest (AD forest) is the top most logical container in an Active Directory configuration that contains domains, and objects such as users and computers.

#### G

### **Gateway Connector**

The Keyfactor Gateway Connector is installed in the customer forest to provide a connection between the on-premise CA and the Azure-hosted, Keyfactor managed Hosted Configuration Portal to provide support for synchronization, enrollment and management of certificates through the Azure-hosted instance of Keyfactor Command for the on-premise CA. It is supported on both Windows and Linux.

#### н

### **Host Name**

The unique identifier that serves as name of a computer. It is sometimes presented as a fully qualified domain name (e.g. servername.keyexample.com) and sometimes just as a short name (e.g. servername).

### **Hosted Config Portal**

The Keyfactor Hosted Configuration Portal is used to configure connections between on-premise instances of the Keyfactor

Gateway Connector and and on-premise CAs to make them available to Azure-hosted instance of Keyfactor Command. The portal is Azure-hosted and managed by Keyfactor.

### **Hosted Configuration Portal**

The Keyfactor Hosted Configuration Portal is used to configure connections between on-premise instances of the Keyfactor Gateway Connector and and on-premise CAs to make them available to Azure-hosted instance of Keyfactor Command. The portal is Azure-hosted and managed by Keyfactor.

#### Hostname

The unique identifier that serves as name of a computer. It is sometimes presented as a fully qualified domain name (e.g. servername.keyexample.com) and sometimes just as a short name (e.g. servername).

#### ı

### Java Agent

The Java Agent, one of Keyfactor's suite of orchestrators, is used to perform discovery of Java keystores and PEM certificate stores, to inventory discovered stores, and to push certificates out to stores as needed.

### Java Keystore

A Java KeyStore (JKS) is a file containing security certificates with matching private keys. They are often used by Java-based applications for authentication and encryption.

#### **JKS**

A Java KeyStore (JKS) is a file containing security certificates with matching private keys. They are often used by Java-based applications for authentication and encryption.

#### K

### **Key Length**

The key size or key length is the number of bits in a key used by a cryptographic algorithm.

### **Key Pair**

In asymmetric cryptography, public keys are used together in a key pair with a private key. The private key is retained by the key's creator while the public key is widely distributed to any user or target needing to interact with the holder of the private key.

### **Key Size**

The key size or key length is the number of bits in a key used by a cryptographic algorithm.

### **Key Type**

The key type identifies the type of key to create when creating a symmetric or asymmetric key. It references the signing algorithm and often key size (e.g. AES-256, RSA-2048, Ed25519).

### **Keyfactor CA Management Gateway**

The Keyfactor CA Management Gateway is made up of the Keyfactor Gateway Connector, installed in the customer forest to provide a connection to the local CA, and the Azure-hosted and Keyfactor managed Hosted Configuration Portal. The solution is used to provide a connection between a customer's on-premise CA and an Azure-hosted instance of Keyfactor Command for synchronization, enrollment, and management of certificates.

### **Keyfactor Gateway Connector**

The Keyfactor Gateway Connector is installed in the customer forest to provide a connection between the on-premise CA and the Azure-hosted, Keyfactor managed Hosted Configuration Portal to provide support for synchronization, enrollment and management of certificates through the Azure-hosted instance of Keyfactor Command for the on-premise CA. It is supported on both Windows and Linux.

### **Keyfactor Universal Orchestrator**

The Keyfactor Universal Orchestrator, one of Keyfactor's suite of orchestrators, is used to interact with servers and devices for certificate management, run SSL discovery and management tasks, and manage synchronization of certificate authorities in remote forests. With the addition of custom extensions, it can provide certificate management capabilities on a variety of platforms and devices (e.g. Amazon Web Services (AWS) resources, Citrix\NetScaler devices, F5 devices, IIS stores, JKS keystores, PEM stores, and PKCS#12 stores) and execute tasks outside the standard list of certificate management functions. It runs on either Windows or Linux servers or Linux containers.

### **Keystore**

A Java KeyStore (JKS) is a file containing security certificates with matching private keys. They are often used by Java-based applications for authentication and encryption.

#### i.

#### **Logical Name**

The logical name of a CA is the common name given to the CA at the time it is created. For Microsoft CAs, this name can

be seen at the top of the Certificate
Authority MMC snap-in. It is part of the
FQDN\Logical Name string that is used to
refer to CAs when using command-line tools
and in some Keyfactor Command configuration settings (e.g. ca2.keyexample.com\Corp Issuing CA Two).

### M

### **MAC Agent**

The MAC Agent, one of Keyfactor's suite of orchestrators, is used to manage certificates on any keychains on the Mac on which the Keyfactor MAC Agent is installed.

#### Metadata

Metadata provides information about a piece of data. It is used to summarize basic information about data, which can make working with the data easier. In the context of Keyfactor Command, the certificate metadata feature allows you to create custom metadata fields that allow you to tag certificates with tracking information about certificates.

#### C

### **Object Identifier**

Object identifiers or OIDs are a standardized system for identifying any object, concept, or "thing" with a globally unambiguous persistent name.

#### OID

Object identifiers or OIDs are a standardized system for identifying any object, concept, or "thing" with a globally unambiguous persistent name.

#### **Orchestrator**

Keyfactor orchestrators perform a variety of functions, including managing certificate stores and SSH key stores.

#### P

#### P12

A PFX file (personal information exchange format), also known as a PKCS#12 archive, is a single, password-protected certificate archive that contains both the public and matching private key and, optionally, the certificate chain. It is a common format for Windows servers.

#### **P7B**

A PKCS #7 format certificate file is a base64-encoded certificate. Since it's presented in ASCII, you can open it in any text editor. PKCS #7 certificates always begin and end with entries that look something like ---- BEGIN CERTIFICATE---- and ----END CERTIFICATE----. Unlike PEM files, PKCS #7 files can contain only a certificate and its certifiate chain but NOT its private key. Extensions of .p7b or .p7c are usually seen on certificate files of this format.

# P7C

A PKCS #7 format certificate file is a base64-encoded certificate. Since it's presented in ASCII, you can open it in any text editor. PKCS #7 certificates always begin and end with entries that look something like ---- BEGIN CERTIFICATE---- and ----END CERTIFICATE----. Unlike PEM files, PKCS #7 files can contain only a certificate and its certifiate chain but NOT its private key. Extensions of .p7b or .p7c are usually seen on certificate files of this format.

#### **Parameter**

A parameter or argument is a value that is passed into a function in an application.

#### PEM

A PEM format certificate file is a base64-encoded certificate. Since it's presented in ASCII, you can open it in any text editor. PEM certificates always begin and end with entries like ---- BEGIN CERTIFICATE---- and ----END CERTIFICATE----. PEM certificates can contain a single certificate or a full certifiate chain and may contain a private key. Usually, extensions of .cer and .crt are certificate files with no private key, .key is a separate private key file, and .pem is both a certificate and private key.

#### **PFX**

A PFX file (personal information exchange format), also known as a PKCS#12 archive, is a single, password-protected certificate archive that contains both the public and matching private key and, optionally, the certificate chain. It is a common format for Windows servers.

### **PKCS #7**

A PKCS #7 format certificate file is a base64-encoded certificate. Since it's presented in ASCII, you can open it in any text editor. PKCS #7 certificates always begin and end with entries that look something like ---- BEGIN CERTIFICATE---- and ----END CERTIFICATE----. Unlike PEM files, PKCS #7 files can contain only a certificate and its certifiate chain but NOT its private key. Extensions of .p7b or .p7c are usually seen on certificate files of this format.

### PKCS#12

A PFX file (personal information exchange format), also known as a PKCS#12 archive,

is a single, password-protected certificate archive that contains both the public and matching private key and, optionally, the certificate chain. It is a common format for Windows servers.

#### PKI

A public key infrastructure (PKI) is a set of roles, policies, and procedures needed to create, manage, distribute, use, store and revoke digital certificates and manage public-key encryption.

### **Private Key**

Private keys are used in cryptography (symmetric and asymmetric) to encrypt or sign content. In asymmetric cryptography, they are used together in a key pair with a public key. The private or secret key is retained by the key's creator, making it highly secure.

### **Public Key**

In asymmetric cryptography, public keys are used together in a key pair with a private key. The private key is retained by the key's creator while the public key is widely distributed to any user or target needing to interact with the holder of the private key.

### **Public Key Infrastructure**

A public key infrastructure (PKI) is a set of roles, policies, and procedures needed to create, manage, distribute, use, store and revoke digital certificates and manage public-key encryption.

#### R

### **Rogue Key**

A rogue key, in the context of Keyfactor Command, is an SSH public key that appears in an authorized\_keys file on a server managed by the SSH orchestrator without authorization.

#### **Root of Trust**

A root of trust (RoT) is a source within a cryptographic system that can always be trusted. It is typically a hardened hardware module. HSMs (hardware security modules) and TPMs (trusted platform modules) are examples of RoTs.

#### RoT

A root of trust (RoT) is a source within a cryptographic system that can always be trusted. It is typically a hardened hardware module. HSMs (hardware security modules) and TPMs (trusted platform modules) are examples of RoTs.

#### **RPC**

Remote procedure call (RPC) allows one program to call a function from a program located on another computer on a network without specifying network details. In the context of Keyfactor Command, RPC errors often indicate Kerberos authentication or delegation issues.

### rsyslog

Rsyslog is an open-source software utility used on UNIX and Unix-like computer systems for forwarding log messages in an IP network.

#### S

#### SAN

The subject alternative name (SAN) is an extension to the X.509 specification that allows you to specify additional values when enrolling for a digital certificate. A variety of SAN formats are supported, with DNS name being the most common.

### server name indication

Server name indication (SNI) is an extension to TLS that provides for including the host-name of the target server in the initial hand-shake request to allow the server to respond with the correct SSL certificate or allow a proxy to forward the request to the appropriate target.

#### **SMTP**

Short for simple mail transfer protocol, SMTP is a protocol for sending email messages between servers.

### SNI

Server name indication (SNI) is an extension to TLS that provides for including the host-name of the target server in the initial hand-shake request to allow the server to respond with the correct SSL certificate or allow a proxy to forward the request to the appropriate target.

### SSH

The SSH (secure shell) protocol provides for secure connections between computers. It provides several options for authentication, including public key, and protects the communications with strong encryption.

### SSL

TLS (Transport Layer Security) and its predecessor SSL (Secure Sockets Layer) are protocols for establishing authenticated and encrypted links between networked computers.

### **Subject Alternative Name**

The subject alternative name (SAN) is an extension to the X.509 specification that allows you to specify additional values when enrolling for a digital certificate. A variety of

SAN formats are supported, with DNS name being the most common.

#### т

#### **Template**

A certificate template defines the policies and rules that a CA uses when a request for a certificate is received.

### **TLS**

TLS (Transport Layer Security) and its predecessor SSL (Secure Sockets Layer) are protocols for establishing authenticated and encrypted links between networked computers.

#### **Trusted CA**

A certificate authority in the forest in which Keyfactor Command is installed or in a forest in a two-way trust with the forest in which Keyfactor Command is installed.

#### U

#### **Untrusted CA**

A certificate authority in a forest in a oneway trust with the forest in which Keyfactor Command is installed or in a forest that is untrusted by the forest in which Keyfactor Command is installed. Non-domain-joined standalone CAs also fall into this category.

#### W

### Web API

A set of functions to allow creation of applications. Keyfactor offers the Keyfactor API, which allows third-party software to integrate with the advanced certificate enrollment and management features of Keyfactor Command.

### **Windows Orchestrator**

The Windows Orchestrator, one of Keyfactor's suite of orchestrators, is used to manage synchronization of certificate authorities in remote forests, run SSL discovery and management tasks, and interact with Windows servers as well as F5 devices, NetScaler devices, Amazon Web Services (AWS) resources, and FTP capable devices, for certificate management. In addition, the AnyAgent capability of the Windows Orchestrator allows it to be extended to create custom certificate store types and management capabilities regardless of source platform or location.

### Workflow

A workflow is a series of steps necessary to complete a process. In the context of Keyfactor Command, it refers to the workflow builder, which allows you automate event-driven tasks when a certificate is requested or revoked.

#### X

#### x.509

In cryptography, X.509 is a standard defining the format of public key certificates. An X.509 certificate contains a public key and an identity (e.g. a host name or an organization or individual name), and is either signed by a certificate authority or self-signed. When a certificate is signed by a trusted certificate authority it can be used to establish trusted secure communications with the owner of the corresponding private key. It can also be used to verify digitally signed documents and emails.
